Copyright, in the United States of America, 1911, by The Encyclopædia Britannica Company.
INITIALS USED IN VOLUME XVIII. TO IDENTIFY INDIVIDUAL CONTRIBUTORS,\(^1\) WITH THE HEADINGS OF THE ARTICLES IN THIS VOLUME SO SIGNED.

A. Ca.  
Arthur Cayley, LL.D., F.R.S.  
See the biographical article, Cayley, Arthur.

A. E. G.  
Rev. Alfred Ernest Garvie, M.A., D.D.  
Principal of New College, Hampstead. Member of the Board of Theology and the Board of Philosophy, London University. Author of *Studies in the Inner Life of Jesus*; &c.

A. E. S.  
Arthur Everett Shipley, M.A., D.Sc., F.R.S.  

A. F. P.  
Alfred Frederick Pollard, M.A., F.R.S., H.S.  
Professor of English History in the University of London. Fellow of All Souls' College, Oxford. Assistant Editor of the *Dictionary of National Biography*, 1893-1901. Lothian Prize (Oxford), 1892; Arnold Prize, 1898. Author of *England under the Protector Somerset; Henry VIII.; Life of Thomas Cranmer*; &c.

A. Go.*  
Rev. Alexander Gordon, M.A.  
Lecturer on Church History in the University of Manchester.

A. G. D.  
Arthur George Doughty, M.A., Litt.D., C.M.G.  
Dominion Archivist of Canada. Member of the Geographical Board of Canada. Author of *The Cradle of New France*; &c. Joint-editor of *Documents relating to the Constitutional History of Canada*.

A. Ha.  
Adolf Harnack.  
See the biographical article, Harnack, Adolf.

A. H.-S.  
Sir A. Houtum-Schindler, C.I.E.  
General in the Persian Army. Author of *Eastern Persian Irak*.

A. J. G.  
Rev. Alexander James Grieve, M.A., B.D.  
Professor of New Testament and Church History at the United Independent College, Bradford. Sometime Registrar of Madras University and Member of Mysore Educational Service.

A. J. L.  
Andrew Jackson Lamoureux.  
Librarian, College of Agriculture, Cornell University. Formerly Editor of the *Rio News*, Rio de Janeiro.

A. L.  
Andrew Lang.  
See the biographical article, Lang, Andrew.

A. M. C.  
Agnes Mary Clerke.  
See the biographical article, Clerke, A. M.

A. N.  
Alfred Newton, F.R.S.  
See the biographical article, Newton, Alfred.

A. Se.*  
Adam Sedgwick, M.A., F.R.S.  
Professor of Zoology at the Imperial College of Science and Technology, London. Fellow, and formerly Tutor, of Trinity College, Cambridge. Professor of Zoology in the University of Cambridge, 1907-1909.

A. V. G.  
Baron Alfred von Gutschmid.  
See the biographical article, Gutschmid, Alfred, Baron von.

A. Wa.  
Arthur Waugh, M.A.  

\(^1\) A complete list, showing all individual contributors, appears in the final volume.
INITIALS AND HEADINGS OF ARTICLES

B. J.
BERNHARD JÜGL (1832-1886).
Formerly Professor of Classical Philology in the University of Innsbrück. Author of Mongols: Language.

B. M.*
BUDGETT MEAKIN (1866-1906).

MEDAL (Fr. médaille, from Lat. metalum), strictly the term given to a memorial piece, originally of metal, and generally in the shape of a coin, used however not as currency but as an artistic product. "Medallion" is a similar term for a large medal, but is now usually restricted to a form of bas-relief in sculpture. The term "medal" is, artistically, extended by analogy to pieces of the same character not necessarily shaped like coins. The history of coins and medals is inseparable, and is treated under the general heading of Numismatics. That article may be supplemented here by an account of (1) the more recent progress in the art of the medallist, and (2) the use of medals for war decorations.

1. The medal—as it is understood to-day—enjoys a life entirely independent of the coin on the one hand, and, on the other, of the sculptured medallion, or bas-relief; and its renaissance is one of the chief phenomena in art during the period since about 1870. It is in France that it has risen to the greatest perfection. Its popularity there is well-nigh universal; it is esteemed not only for memorials of popular events and of public men, but also for private celebrations of all kinds. No other nation approaches in excellence—in artistic feeling, treatment, and sensitiveness of execution—the artists and the achievements of France. In England, although the Royal Academy seeks to encourage its students to practise the art, the prize it offers commonly induces no competition. The art of the medallist is not properly appreciated or understood, and receives little or no support. The prevailing notion concerning it is that it consists in stamping cheap tokens out of white metal or bronze, on which a design, more or less vulgar, stands out from its relief from a dazzling, glittering background. These works, even the majority of military and civic medals, demonstrate how the exquisite art of the Renaissance had been degraded in England—almost without protest or even recognition—so that they are, to a work of Roty or Chaplain, what a nameless daub would be to a picture by Rembrandt or Velasquez.

It is probable that Jacques Wiener (d. 1809), of Belgium, was the last of the medallists of note who habitually cut his steel dies entirely with his own hand without assistance, though others in some measure do so still. Although most modern workers, exclusively medallists, have themselves cut dies, they now take advantage of the newest methods; and the graveur en médaillages has become simply a médailleur. His knowledge of effect is the same—though the effect sought is different: in earlier times the artist sought chiefly of his shadows; now he mainly regards his planes. Otherwise his aims are not dissimilar. At the present day the medallist, after making conscientious studies from life (as if he were about to paint a picture), commonly works out his design in wax, or similar substance, upon a disk of plaster about 12 or 14 inches in diameter. From that advanced model a simple mould, or matrix, is made, and a plaster cast is taken, whereupon the artist can complete his work in the utmost perfection. Then, if a struck medal is required, a steel cast is made, and from that a reduction to the size required for the final work is produced by means of the machine—the tour à réduire. It is this machine which has made possible the modern revival, and has revolutionized the taste of designers and public alike. It was invented by Contamin, who based it upon that tour à portrait which Houlot produced in 1766, and which helped to fame several engravers now celebrated. This machine was first exhibited in Paris in 1839, and was sold to the Munich Mint; while a similar invention, devised at the same time by the English engraver Hill, was acquired by Wyon for £2000, and was ultimately disposed of to a private mint in Paris. From that city comes the machine, based by the French inventor M. Ledru upon the two already referred to, now in use at the Royal Mint in London. A well-versed medallist, therefore, need trouble himself nowadays about little beyond the primary modelling and the final result, correcting with his own hand only the slightest touches—refining, perfecting—but sometimes merely confining himself to giving his directions to the professional engraver.1

The great majority of the artistic medals at present in the world (in the great collection of France there is a total of not fewer than 200,000 medals) are cast, not struck. There is in them a charm of surface, of patina, of the metal itself, which the struck medal, with all the added beauties which it allows of delicate finish and exquisite detail, can hardly give. But the production of the cast medal is much slower, much more uncertain, and the number of fine copies that can be produced is infinitely smaller. All the early medals were cast, being first modelled in wax, and then cast by the cire perdue (waste wax) method of preparing the dies, &c., is the same for medals as for coins, save that for larger and heavier work more strokes are required, as in the case of L. Coudray's popular "Orphée"—rather a sculpture-relief than a medal. The dies are capable of a great yield before becoming quite worn-out; it is said that no fewer than three million copies were struck of Professor J. Tautenhayn's Austrian Jubilee medal of the Emperor Francis Joseph. In France, Thonellier's perfected machine, substituting the lever for the screw, has been in use for coins since 1844; but for the striking of medals the same old-fashioned screw-press retains which had till then been employed both for coins and medals since the time of Louis XIV. In its present form the machine consists of an iron or bronze frame, of which the upper part is fitted with a hollow screw wherein works an inner screw. This screw, moved by steam or electricity, drives the dies, set in iron collars, so that they strike the blank placed between them. This machine can deliver a strong blow to produce a high relief, or a delicate touch to add the finest finish. In the Paris Mint large medals can be struck with comparative ease and rapidity. A hydraulic press of nearly two million pounds pressure is utilized for testing the dies.

XVIII. 1
process, and were usually worked over by the chaser afterwards; indeed, it was not until the beginning of the 16th century that dies, hitherto used only for coins executed in low relief, were employed for larger and bolder work. The medallists of those days always cast in bronze or lead, and only proceeded to use silver and gold as a luxurious taste began to demand the more precious metals. There is little doubt that the material to be preferred is dull silver (mat or sablé—sand-blasted), as the work, with all its variations of light and shade, can be better seen in the delicate grey of the surface.

The medal, properly considered, is not sculpture. Vasari was happy in his definition when he described the medallic art as the link between sculpture and painting—that is to say, painting in the round with the colour left out. Less severe than sculpture, it need not be less dignified; it is bound down by the conventions of low relief, and by compulsions of composition and design, dependent on shape, from which sculpture, even when the relief is the lowest, is in a great measure free.

In the medal, otherwise than in sculpture, elaborate perspective and receding planes are not out of place. The genius of the modern Frenchman rebelled against the rule that commonly governs the composition of medals, and has triumphed in his revolt, justifying the practice by his success. The medal and the plaque aim at being decorative yet vigorous, reticent and dignified, delicate and tender, graceful and pure; it may be, and often is, all these in turn. Imagination, fancy, symbolism, may always be brought into play, allied to a sense of form and colour, of arrangement and execution. By the demonstration of these qualities the artist is to be differentiated from the skilful, mechanical die-sinker, who spreads over the art the blight of his heavy and insensitive hand and brain. So with portraiture. Accurate likeness of feature as well as character and expression are now to be found in all fine works, such as are seized only by an artist of keenly sensitive temperament.

It is thus that he casts the events and the actions of to-day into metallic history, beautifully seen and exquisitely recorded; thus that the figure on the medal is no longer a mere sculpture-symbool, but a thing of flesh and blood, suave and graceful in composition, and as pleasing in its purely decorative design as imagination can inspire or example suggest.

In the modern medalists—of which the means of permanent memorial, has afforded to men of restricted means the eagerly seized opportunity of forming small collections of masterpieces of art at a small outlay.

France.—In France the example of Oudiné, coming after that of David d’Angers, did much to revolutionize the spirit animating the modern medallist, but Chapu, by his essentially modern treatment, did more. To Ponsarcme (pupil of Oudiné) is chiefly due the development of the ground as well as the subject on the medal, the suppression of the raised lines and the founding of the typographic lettering hitherto in vogue, together with the mechanical regularity of its arrangement. Degeorge, with his pictorial-portrait, was followed by Daniel Dupuis, whose delicate and playful fancy, almost entirely pictorial, makes for a greater value in the material and the die. J. C. Chaplin is unsurpassed as a modeller of noble heads, including those of four presidents of the French Republic—Macmahon, Casimir-Périer, Faure and Labour— and his finely finished plaques have been long admired (see Plate); but L. Oscar Roty (pupil of Ponsarcme) is at the head of the whole modern school, not only by virtue of absolute mastery of the technique of his art, but also by its originality of arrangement. Of the modern French medals, that of the delicate fancy, the exquisite touch, the chasteness and purity of taste—wedding a modern sentiment to an obvious feeling for the Greek. Though expressly less virile than Chaplin, Roty is yet effectively a descendant of that school, having first revived the form of the plaque, or rectangular medal, which had been abandoned and forgotten along with many other traditions of the Renaissance (see Plate). Alphée Dubois, Lagrange, and Borrel must be considered among those who are understood in their own dies. Followers are to be found in Mouchon, Lechere, Verdier, Henri Dubois, Patey, Bottée (see Plate)—all sterling artists if not innovators. Medallists of more striking originality but less finish, and of less elegance of the ground as well as the subject on the medal, J. Michel Cazin, Levillain (who loves as much as Bandinel to make over-display of his knowledge of muscular anatomy), Charpentier, and their school, who aim at a manner which makes less demand of highly educated artistry such as that of Roty or of Chaplin. It is learned and accomplished in its way, but lumpy in its result; breadth is gained, but refinement and distinction are in a great measure lost. It may be added—to give some idea of the industry of the modern medallist, and the encouragement accorded to him—that between 1879 and 1900 he has executed more than 150 pieces, each having an obverse and a reverse.

Austria.—The two leading medallists of the Austrian school are Josef Tautenhayn (see Plate) and Anton Scharf, both highly skilled men who yet not satisfied with the taste, ability and "keeping" which distinguishes the French masters. About 330 pieces have come from the hand of Anton Scharf, Stefan Schwartz, Franz Pawlik, Staniek, Marschall and J. Tautenhayn, justly ranked the only original and genuine modern Austrian medal.

Germany.—A characteristic florid style is here cultivated, such as lends itself to the elaborate treatment of costume, armorial bearings, and the like; but delicacy, distinction, and the highest excellence in modelling and draughtsmanship—qualities which should accompany even the most vigorous or elaborate designs—are lacking in a great degree. Professors Hildebrand and Kowarzik have wrought some of the most artistic works there produced.

Belgium.—Although sculpture so greatly flourishes in Belgium, metal work shows little of the artistic pretensions of its sister. The influence of the three brothers Wiener (Jacques, Léopold and Charles)—good medallists of the old school—has not yet been shaken off. The remarkable architectural series by the first-named, and the reminiscence of the French, an imitation of the Duchesse de Bourgogne medal, is perhaps the best example of Belgian modernism. Lemaire has perhaps done as well as any, followed by Paul Dubois, J. Dillens (a follower of the French), G. Devreese and Vincotte (see Plate)—whose plaque for the Brussels Exhibition was marked with the originality of his pupil—costume, still a finish.

Holland.—In Holland not very much has been done. Patriotism has founded many medals of Queen Wilhelmina, and the best of them are doubtless those of Bart van Hove and Wortman. Baars is the only Dutch artist who follows Chaplin at a distance, and his extensive cypher medal is interesting for the sake of his early Netherlandish manner; the incongruity is not unpleasant.

Switzerland.—The medal is also popular in Switzerland. Here both Léopold and Henri Wiener, and Hans Priel of a more national sentiment. The last-named, however, is more remarkable as a revivalist than as an original artist.

Great Britain.—In England only two medals of repute can be practically mentioned in recent years, the art—G. W. de Castell of the Royal Mint, best known by the Diamond Jubilee medal of Queen Victoria and by his medal of Sir Gabriel Stokes, and Frank Bowcher (see Plate) by that of Thomas Huxley. These artists both cut their own dies when necessary. Emil Fuchs, who worked for the Royal Mint in the 1860's, but with greater freedom than is the wont of the older school, has produced several examples of the art: the medals commemorating the South African War and of Queen Victoria (two versions), all of which have the great merit of being free from all the usual devices. Besides these, the leading English sculptors have produced medals—Lord Leighton, Sir Edward Poynter, Hano Thyncroft, T. Brock, Ossows Ford, G. Frampton and Sir George Frampton (see Plate)—though the true antiques are not in the same hands. The sculptors, however, do not claim rank as medallists, nor have they sought to acquire that class of dexterity which constant habit alone can give. Alphonse Legros, who has cast a certain number of portrait medals, is usually included in the former group.

United States.—Among American medallists Augustus St Gaudens (see Plate) is perhaps the most prominent; but he is not, strictly speaking, a medallist, but a sculptor who can model in the flat.

MEDALS AS WAR DECORATIONS

Although the striking of medals to commemorate important events is a practice of considerable antiquity, yet the custom of using the medal as a decoration, and especially as a decoration to do honour to those who have rendered service to the state...

MEDAL

in time of war, is comparatively modern. It has been supposed that the circular ornaments on the Roman standards had medals in their centres, but there is no evidence to show that this was the case, and the standards shown on the column of Trajan appear only to have had plain bosses in their centres. It is true that the Chinese are said to have used military medals during the Han dynasty (1st century A.D.), but, as far as the West is concerned, we have to come to the 16th century before we find the custom of wearing medals as decorations of honour a recognized institution.

The wearing of decorative medals was common in England in the reign of Henry VIII., but the first medals commemorating a particular event that were evidently intended as a personal decoration, and were in all probability (though there is no absolute proof) bestowed as reward for military services rendered to the Crown, are the "Armada" medals of Queen Elizabeth, 1588-1589. Of these there are two. The earliest, generally styled the "Ark in flood" medal, is a large oval medal of silver (2 by 1-75 in.), and bears on the obverse a profile bust of the queen surrounded by the inscription, ELIZABETH D. G. ANGLAE. F. ET H. REG. On the reverse is an ark on waves, with above the rays of the sun, and around the legend, SAEVAS TRANQUILHA PER VNDAIS. This medal dates from 1588, and in the following year there was given another medal, a little larger (2-3 by 2-1 in.) and struck in gold, silver and copper. The obverse of this second medal bore a full-face bust of Elizabeth, with the legend, characteristic both of the monarch and the period, DITIOR IN TOTO NON ALTER CIRCULUS ORBE. The reverse has an island around which ships are sailing and sea-monsters swimming, and on the island there are houses, a flourishing bay-tree, standing unjurbed by a storm of wind, and lightning emerging from heavy clouds above. The island is inscribed NON IPSA PERICVLA TANGVNT. These medals are of special interest as demonstrating thus early the existence of a doctrine of sea-power, and of James I. (1603-1625), none of which have a distinct reference to war services, the "ark in flood" design was again reproduced on the reverse, this time with the legend slightly altered, viz. STET SALVVS IN VNDIS.

Other European nationalities were also about this period conferring decorative medals as a reward for war services, as for example, the "Medal to Volunteers" issued in Holland in 1622-1623 and the "Military Medal of Gustavus Adolphus" issued in Sweden in 1630. Here it may be noted that in following the history of medals as used as a decoration to reward military services, only those of British origin need be dealt with in detail, since Great Britain has utilized them in a much greater degree than any other nationality. The countless minor wars of the 19th century, waged by the forces of the Crown of every class, navy, army and auxiliary, have no equivalent in the history of other states, even in that of France, the United States and Russia. The great wars of the 19th century were divided by long intervals of peace, and the result is that with most of the great military powers the issue of campaign medals has been on a small scale, and in the main decorations have taken the form of "Orders" (see Knighthood and Chivalry: Orders), or purely personal decorations for some meritorious or exemplary service.

During the reign of Charles I. (1625-1649), we come across numerous medals and badges; a considerable number of these were undoubtedly associated with, and given, even systematically given, as rewards for war services; for a royal warrant "given at our Court of Oxford, the eighteenth day of May, 1643," which directed "Sir William Parkhurst, Knight, and Thomas Bushell, Esquire, Wardens of our Mint, to provide from time to time certain Badges of silver, containing our Royal image, and that of our dearest son, Prince Charles, to be delivered to the members of his majesty's army, and bestowed on the breast of every man who shall be certified under the hands of their Commanders-in-Chief to have done us faithful service in the Fornord-hope."

From the foregoing it must not be deduced that this medal was in any way intended to reward special valour. In those days "fornord-hopes" were not volunteers for some desperate enterprise, as to-day, but a tactical advanced guard which naturally varied, both in numbers and arm of the service, according to ground and circumstances. That a very free distribution of the award was contemplated is evident from the fact that "soldiers" alone were specified as recipients and that a clause was inserted in the warrant strictly inhibiting the sale of the medal. This letter ran:—

"And we do, therefore, most strictly command, that no soldier at any time do sell, nor any of our subjects presume to buy, or wear, any of these said Badges, other than they to whom we shall give the same, and that under such pain and punishment as our Council of War shall think fit to inflict, if any shall presume to offend against this our Royal command."

As there are in existence several medals of this period which bear the effigies of both the king and Prince Charles, it is uncertain which in particular was used for the "fornord-hope" award. Very probably it is one, an oval silver-gilt medal (2-7 by 1-3 in.) which bears on the obverse a three-quarters (3/4) bust of Charles, and on the reverse a profile (l.) bust of Prince Charles (see Mayo, Medals and Decorations of the British Army and Navy, vol. I. No. 16, Plate 5, No. 3). During the Commonwealth (1649-1660), parliament was lavish in the award of medals in recognition of war services, and for the first time we find statutory provision made for their bestowal as naval awards, in the shape of acts of parliament passed Feb. 22, 1648 and April 7, 1649 (cap. 12, 1648 and cap. 21, 1649), and Orders in Council of May 8 and Nov. 19 and 21, 1649, and Dec. 20, 1652. There is no doubt whatever that there was a "Medal of the Parliament" for sea service issued in 1649. This medal, oval (-95 by -85 in.) and struck in gold and silver, had on the obverse an anchor, from the stock of which are suspended two shields, one bearing the cross of St. George, and the other the Irish harp. The motto is MERVISI. On the anchor stock, T. S. The reverse has on it the House of Commons with the Speaker in the chair. This medal is referred to in a minute of the Council of State of Nov. 15, 1649:

"(5) That the Formes of the medalls which are now brought in to be given to the severall Mariners who have done good service this last Sufter be approved off, viz: the Arms of the Comon wealth on one side with Meruisht written above it, and the picture of the House of Coffions on the other."

That there was a "Medal of the Parliament" for land service as well, is proved by the following extract from the Journals of the House of Commons (vii. 6, 7):—

"Resolved, That a Chain of Gold, with the Medal of the Parliament, to the Value of One Hundred Pounds, be sent to Colonel Mackworth, Governor of Shrewsbury, as a mark of the Parliament's Favour, and good acceptance of his fidelity: And that the Council of State do take care for the providing the same, and sending it forthwith."

This order was duly carried out, as is shown in the minutes of the Council of State, June 2 and July 30, 1652, but there is no trace to-day of either medal or chain. It is not unlikely that this medal is one figured at page 117 of Evelyn's Numismata (the engraving, unnumbered, is placed between Nos. 39 and 40, and there is no allusion to it in the text), which has on the reverse a representation of the parliament, and on the reverse a bust of the Protector with a camp and troops in the background.

The most splendid of all the naval awards of this period were those given for the three victories over the Dutch in 1653, namely:—

1 Thomas Simon, master and chief graver of the mint. Most of the medals of this period were his work, and they are considered to be amongst the best specimens of the medallic art that have been produced in the country.
MEDAL

1. The fight of Feb. 18/20, when Blake, Deane and Monk defeated Van Tromp and De Ruyter, the battle beginning off Portland and ending near the Essex coast, when Monk, Deane (killed), Penn and Blake, again defeated Van Tromp and De Ruyter; (2) the fight of 31st of July off the Texel, in which Monk, Penn and Lawson beat Van Tromp in what was the decisive action of the war. The authorization for these awards will be found recorded in the Journals of the House of Commons (vii. 206, 207), under date Aug. 8, 1653. The medals, all oval, and in gold, were given in three sizes, as described below:

A (2-2 by 2 in.). Only four of these medals were issued, to Admirals Blake and Monk, each with a gold chain of the value of £300, and to Vice-Admiral Penn and Rear-Admiral Lawson, each with a gold chain of the value of £300. On the obverse is an anchor, from the stock of which are suspended three shields, bearing respectively St. George's cross, the saltire of St. Andrew, and the Irish harp, the whole encircled by the cable of the anchor. On the reverse is depicted a naval battle with, in the foreground, a sinking ship. Both obverse and reverse have been struck with very handsome border of naval trophies, and on the obverse side this border has imposed upon it the arms of Holland and Zeeland. Of these four medals three are known to be in existence. One, lent by the warden and fellows of Wadham College, Oxford (Blake, it may be noted, was a member of Wadham College) was exhibited at the Royal Naval Exhibition of 1891. A second is in the royal collection at Windsor Castle. The third, with its chain, is in the possession of the family of Stuart of Tempford House, Bedfordshire. This latter medal is known to have been the one given to Vice-Admiral Penn, an ancestor of the Stuart family. The one at Windsor is presumably Blake's, as Tancred states "the medal given to Blake was purchased for William IV. at the price of 150 guineas (Tancred, Historical Records of Medals, p. 30). The medal at Wadham was formerly in Captain Hamilton's collection. He purchased it at a low figure, but secrecy was kept so that no one knew the original chain that was with it went into the melting-pot: there is therefore nothing to show whether it was Monk's or Lawson's, as the chain would have done. It was sold at Sotheby's in May 1882 for £305.

B (2 by 1-8 in.). Four of these medals were issued, each with a gold chain of the value of £20, to the "Flag Officers," i.e. to the flag captains who commanded the four flag-ships. The obverse and reverse of this medal are, with the exception of the borders, precisely as in (A). The borders on both sides are a little narrower than those of (A), and of laurel instead of trophies. One of these medals—that given to Captain William Haddock, who was probably Monk's flag-captain in the "Vanguard," in the February fight, as he had been in that ship in the previous year, and who commanded the "Hannibal," (44) in the June battle—is now (1909) in the possession of Mr. C. D. Holworthy, who is maternally descended from Captain Haddock.

C (1 by 1-4 in.). This medal is precisely the same as (B), but has no border of any kind, and also was issued without the gold chains. It was in all probability one that was issued in some numbers to the captains and other senior officers of the fleet.

Some of these medals have in the plate of the reverse an inscription: FOR EMINENT SERVICE IN SAVING Y TRIUMPH FIERED IN FIGHT WH Y DVCelah IN JULY 1653. The medal so inscribed was given only to those who served in the "Triumph," and commemorates a special service. Blake, incapacitated by wounds received in the fight of February, took no part in this action, but his historic flag-ship, the "Triumph," formed part of the fleet, and early in the battle was fired by the Dutch fire-ships. Many of the crew threw themselves overboard in a panic, but those who remained on board succeeded by the most indomitable and heroic efforts in subduing the flames, and so saving the vessel.

But undoubtedly the most interesting of all the medals of the Commonwealth period, is that known as the "Dunbar Medal," authorized by parliament, Sept. 10, 1650, in a resolution of which the following is an extract:

"Ordered, that it be referred to the Committee of the Army, to consider what Medals may be prepared, both for Officers and Soldiers, that were in this Service in Scotland; and set the Proportions and Values of them, and their number; and present the Estimate of them to the House. (Journals of the House of Commons, vii. 464-465.)"

So came into being, what, in a degree, may be regarded as the prototype of the "war medal" as we know it to-day, for the "Dunbar Medal" is the very earliest that we know was issued to all ranks alike, to the humblest soldiers as well as to the commander-in-chief. It differed however in one very material point from the war medal of to-day—in that it was issued in two sizes, and in several different metals. There is no evidence to show what was the method that governed the issue of this medal; but the medal itself undoubtedly varied in size or metal, or both, according to the rank of the recipient. Of the two sizes in which the medal was issued, the smaller, 1 by .85 in. was apparently intended for seniors in the respective grades, for it was struck in gold, silver and copper. The larger, 1.35 by 1.15 in. was struck in silver, copper and lead (see Mayo. op. cit. i. 20-21). On the obverse of both issues of the "Dunbar Medal" is a left profile bust of Oliver Cromwell, with, in the distance, a battle. The reverse of the larger medal has the parliament assembled in one House with the Speaker; and, on the left, a member standing addressing the chair. The reverse of the smaller medal is the same as that of the larger, except that the member addressing the House is omitted. Cromwell himself expressed a wish to the "Committee of the Army, at London," in a letter dated the 4th of February 1650/51, that his likeness, to procure which accurately the committee had sent Mr. Simon to Scotland, should not appear on the medal. He writes:

"If my poor opinion may not be rejected by you, I have to offer to which I think the most noble end, to wit, The Commemoration of that great Mercie att Dunbar, and the Gratuitie to the Army, which might be better expressed upon the Medall, by engraving as on the one side the Parliament which I hear was intended and will do similarly well. So the other side an Anchor, with this inscription over the head of it, The Lord of Hosts which was our Word that day. Wherefore, if I may beg it as a favour from you, I most earnestly beseech you, if I may do it without ofence, that you will cause this to be done. If you will have any other offer, you may alter it as you see cause; only I doe think I may truly say, it will be very thankfully acknowledged by me, if you will spare the having my Effigies in it."

In spite of this request Cromwell's "Effigies" is made the prominent feature of the obverse of the medal, to which the representation of the "Army" is entirely subordinated. His wish that the "word" for the day should be commemorated is, however, observed in the legend on the obverse, as is also, on the reverse, his suggestion that on one side of the medal there should be a representation of the parliament.

During the reign of Charles II. the issue of medals was numerous, and though we have it on the authority of Evelyn that many of these were bestowed as "gratuities of respect," yet many were given as naval awards. At this time, there appears official authorization for the conferring of particular awards on those who had succeeded in the very hazardous service of destroying an enemy's vessel by the use of fire-ships. In what are probably the earliest "Fighting Instructions" issued—those of Sir William Penn, in 1653, and again in an abridged form in 1655—allusion to these awards is made, but that the custom of rewarding this special service prevailed, there is a piece of strong indirect evidence to show, in the shape of an amusing letter from a certain Captain Cranwill, of "ye Hare Pinke," to the Admiralty Committee, dated Feb. 4, 1655:

3 An excellent reproduction of this medal, both obverse and reverse, is given in Plate 8, figs. 4 and 5, of the same work, and on Plate 9 will be found equally well reproduced facsimiles of the three medals for "Victories over the Dutch, 1653," figs. 1, 2 and 3 and of the "Medal of the Parliament, for Sea Service, 1649," fig. 1.
As for ye Pay or Honrs were please to order mee for my service in ye Hare Pinke, I return most humble thanks, and am ready to serve ye Honrs and my Country for ye future.

For though ye Hare be mewed in ye sand yet Cranwell at your mercy still doth stand
A fire Ship now doth hee Crave,
And the Fox tain would he Have,
then has hee had both Fox and Hare,
then Spanish Admirall stand you cleare,
For Cranwell means ye Chaine of gold to ware;
Sett penn to paper it is done,
for Cranwell still will be your man.

all of which goes to show that it had not been unusual to bestow gold chains, with or without medals, on the captains of fireships. By the "Fighting Instructions" issued 20th of April, 1665, by James, duke of York, lord high admiral, it was provided that in the case of the destruction of an enemy's vessel of forty guns or more, each person remaining on board the fireship till the service was performed was to receive £10, "on board ye Admiral immediately after ye service done," and the captain a gold medal and "shut other future encouragement by present and command shall be fit both to reward him and induce others to perform ye like Service."

If it was a flag-ship that was fired "ye Recompense in money shall be doubled to each man performing itt, and ye medall to ye Commander shall be shut as shall particularly express ye Eminensye of ye Service, and his with ye other officers preferement shalte suitable to ye meritt of itt." This was followed by an "Oder of the King in Council " dated Whitehall 12th of January 1669-1670, in which the lord high admiral is authorized "to distribute a Medall and Chaine to such Captaines of Fire Shippes as in the last Dutch Warrie have burnt any Man of Warr, as also to any of them that shall perform any such service in the present Warr with Algiers. Which Medalls and Chains are to be of the price of Thirty Pounds each or thereabouts"

To complete the story of fire-ships, it may here be noted (though out of chronological order) that in 1703 revised "Fighting Instructions" were issued by Admiral Sir George Rocke, in which it was provided that the captain was to have his choice between a gratuity of £100, or a gold medal and chain of that value. Lastly an order of the king in council, dated, St James's, 16th of December, 1742, ordered that all lieutenants of fire-ships (which originally carried no officers of this rank) should be entitled to a gratuity of £50 "in all cases where the Captain is entitled to the Reward of £100."

Though probably others were conferred, so thorough an investigation as that of John Hurdley Mayo, for many years military secretary at the India office, who had special opportunities of access to official records, traced but three authenticated fire-ships. Those were: (1) to Captain John Guy, who blew up his fire-ship the "Vesuvius" under the walls of St Malo in 1653; (2) to Captain Smith Callis who, with his fire-ship the "Duke," in 1742, destroyed five Spanish galleys which had put into St Tropez, to the eastward of Marseilles; (3) to Captain James Woolridge, who commanded the British fire-ships in Aix Roads on the 11th of April 1809, when four French sail of the line were burnt. This latter is believed to be the last award of the kind that was issued. Fire-ships awards are of special interest as affording a precedent, in future naval wars, for the award of special decorations for torpedo services.

It is in this reign also that we first find a case of medals being granted by the Honourable East India Company. The earliest of these would appear to have been a gold medal of the value of £20, conferred on Sir George Oxenden, president at Surat, 1622-1669, in 1668, for considerable civil and military services. Surat was then and until 1687, when Bombay took its place, the seat of government of the Western Presidency, and the most eminent of Sir George's services was the defence of the Company's treasures and possessions at that place against Sivajee and the Maharrats in 1664. It is not known what has become of this medal, but there is indirect evidence to show that it was a circular medal, three inches in diameter. On the obverse the "Arms of the Governor and Company of Merchants of London trading to the East Indies, with crest, supporters, and mottoes," and around the legend NON MINOR EST VIRTVS QUAM QVAERERE PARTA TVERI. The reverse was probably blank to admit of an inscription. This award was the forerunner of many given by the H.E.I. Co., several of which were "general distributions" of the very highest interest, which will be dealt with together later on.

The awards made in the reigns of James II., William and Mary, William III., Anne, George I., George II., may be very briefly dealt with. Almost without an exception they were both naval or conferred by the Hon. East India Company, and with only perhaps one or two exceptions, they were "personal" as distinct from "general" awards. Of the very few medals awarded by James II., one was an undoubted military award, though curiously enough the recipient was a bishop. This was Peter Mew, who had been made bishop of Bath and Wells in 1672, was translated to Winchester 1684, and next year was commanded by the king, in compliance with the request of the gentry of Somerset, to go against Monmouth, and did eminent service at the battle of Sedgemoor, where he managed the artillery; for which he was rewarded with a rich medal" (Hutchins's History of Dorset, 3rd ed., vol. iv. p. 149).

The possible exceptions in the way of a "general" distribution of a medal during the reigns under review are the cases of the medals struck after the battles of La Hogue, 1692, and Culloden, 1746. By an act of parliament passed in 1692 (4 Gul. and Mar. c. 25), it was enacted that a tenth part of the prize money taken by the navy should be set apart "for Medals and other Rewards for Officers, Mariners, and Seamen in their Majesties Service at Sea who shall be found to have done any signal or extraordinary service." (Later a Royal Declaration of Queen Anne, the 1st of June 1702, provided that all medal and monetary awards "shall be also paid out of Her Majesties Shares of Prizes.")) This is the first case in naval records authorising the issue of medals to men as well as to officers, and the confering of the "La Hogue" medal was the first case in which the enactment was carried into effect, at any rate as far as admirals and officers are concerned. Seamen and soldiers had a more substantial reward, for the queen sent £30,000 to be distributed amongst them, whilst gold and silver medals were struck for the admirals and officers. The medal, which was circular, 1.25 in. in diameter, had on the obverse the busts conjoined of William and Mary, r., with around GVL ET MAR D G M B F T H REX ET REGINA. On the reverse was a representation of the fight, showing the French flag-ship, "Le Saint Roy" (The Saint John), with above the legend NOX NVLLA SECVTA EST, and, in the exergue, PVGN NAV INT ANG ET FR 21 MAY 1692.

As regards the medal struck after Culloden, fought on the 16th of April 1746, and in which the adherents of the young Pretender were completely routed, there is nothing even to show that it was issued even by the authority of the government, though it was undoubtedly worn, and (if a contemporary portrait is to be relied upon, that of an ancestor of Mr W. Chandos-Pole of Radbourne Hall in Derbyshire) around the neck attached to a crimson ribbon with a green edge. There is no doubt it was struck in gold, silver and copper, but how it was awarded there is no proof, probably only to officers. The obverse had an r., bust of the duke of Cumberland, with above CUMBERLAND, below YEO I (Richard Yeo fecit), and, on the reverse, a classical figure of a laureate, lion, spear and sword, point ing to a dragon wounded by his arrow. The reverse legend was ACTVM EST IUCIT PERITI, and, in the exergue PROEL COLOD AP XVI MDCCCLXVI. The medal is a strikingly handsome one, with an ornamental border and ring for suspension, oval, 1.75 by 1.45 in., but very few specimens are known to exist. Those in gold were probably only given to officers commanding regiments and a very few specimen of these, originally conferred on Brigadier-General Fleming (at one time in command of the 36th Foot) is now in the collection of Major-General Lord
MEDAL

Cheylesmore. In his monograph, Naval and Military Medals, Lord Cheylesmore mentions another “Culloden” medal in his collection, a slightly larger one in white metal, which leads one to suppose that it was given in honour of the more junior branches, probably officers; but whether this was the case or not I am unable authoritatively to state.” However, one thing is fairly certain, that the issue of the “Culloden” medal was in no sense “general,” as we now understand the term, nor as were the issues for “Dunbar” or the issues of the Honourable East India Company, which will next be dealt with.

No medal awards were made to either the naval or military services for the Seven Years’ War, and the American War of Independence. In fact George III. had been more than thirty years on the throne when the first medal award by the Crown was given, in the shape of the navy gold medals, first issued in 1794. It will however be more convenient to deal later with these medals and the army gold medals and crosses given for services in the long and arduous struggle of 1793-1815, and to describe here in sequence those medals which were issued by the Honourable East India Company, the issue of which was, with certain limitations, “general,” thus reverting to the precedent first established in the “Dunbar” award, namely an issue to all ranks. They are nine in number, and are described below in the chronological order of the military operations for which they were awarded.

1. The “DECCAN” medal. Authorized, first in 1784, and again in 1785. Obverse: Figure of Britannia seated on a military trophy, with her right hand holding a wreath of laurel and extending a forward hand, with a sword in her left hand. This medal was awarded for services in the Bengal army in the civil wars in the Deccan, 1784-85. The reverse is similar to the obverse, the inscription being “FOR SERVICE IN THE DECCAN 1784 & 1785.”

2. The “CEYLON” medal. Authorized, 1793. Obverse: A seated figure of the God of Victory, holding a trumpet in one hand and a sword in the other, with a sword in the left hand, and a torn battle flag on the ground. The reverse shows a globe lying before the God of Victory, with the inscription “FOR SERVICE IN CEYLON.”

3. The “CEYLON” medal. Authorized, 1807. Obverse: An English inscription: “FOR SERVICES ON THE ISLAND OF CEYLON, A.D. 1795-6.” Reverse: A Persian inscription: “This Medal was presented to officers in command of the troops in the island of Ceylon during the years 1795-6.” This medal was issued in only one size, 2 in. diameter, and was awarded to a small force of Bengal native artillery which formed a fraction of a large body of British and native troops (the rest did not receive the medal) which captured Ceylon from the Dutch in 1795-96. It is the only instance of a war medal that has merely a verbal design on both obverse and reverse, and moreover it sets a precedent that was destined to be followed only too often in that it was only granted twelve years after the services was performed. Only 23 medals were struck, two in gold for native officers, and 121 in silver for other ranks. Like the two preceding, it was worn from the neck suspended from a yellow cord.

4. The “SERINGAPATAM” medal. Authorized, 1799, for services in Lord Harris’s campaign of that year, and the storm of Seringapatam. Obverse: A representation of the storming of the breach at Seringapatam, with the meridian sun denoting the time of the storm. In the exergue is a Persian inscription: “The Fort Seringapatam, the 5th of January, 1799.” Reverse: A British lion overcoming a tiger, the emblem of Tippoo Sultan, above is a standard, with the innermost part of the hoist immediately contiguous to the staff, the Union badge, and, in the fly, the lion’s paw (the lion’s head was the badge of the Governor-General). In the exergue: IV. MAY, MDCCCXIX. (the date of the assault). It was in one size, 1-9 in. but of five different kinds. Although the medal was authorized in 1799, it was 1801 before orders for the preparation of 30 gold medals, 15 silver-gilt, 50 silver, 1,000 copper, 5,000 brass, and 15,000 pure tin, were given, the artist being C. H. Kuchler, and the medals made by Matthew Boultun at the Soho Mint, Birmingham. It was 1808 before they came out to India for distribution, and it was not till 1815 that the Company’s European officers were able to receive their medals, or at least some of them, on public ceremonial occasions. For the first time the issue was absolutely “general,” to Europeans as well as natives, to Crown troops as well as to those of the H.E.I. Co., but it was not till 1841, when the First India G.S. Medal of Honour was issued, that the medals were made in all being worn by Europeans in uniform. The medal was given in gold to general officers, in silver-gilt to field officers, in silver to captains and subalterns, in copper bronzed to non-commissioned officers, and in brass to privates. On their return to England no steps were taken with regard to medals till 1807, when medals copied from the Soho Mint one, but 1-8 in. only in diameter, were made at the Calcutta Mint. Following the Bengal perfidious wars was a small number of medals, of which a significant part, the medals were struck in gold for officers, and in silver for the other ranks. A Bengal native officer therefore wore just the same medal as a general officer of any of the other forces, and similarly a Bengal sepoy wore the same medal as a British captain, or soldier of the C.S. Army, and the same medal can easily be distinguished from the others, for in the reverse the artist’s initials C.H.K. are rendered “C.H.M.” Some officers, amongst them Lord Harris himself and his second-in-command Sir David Baird, later an Inspectors-General of the Bengal artillery, wore the medal in the same as that worn with the Army Gold Medal (see below) and was in fact the only authorized military ribbon then in use; but though no ribbon was issued with the medal, recipients were given to wear a ribbon of red and yellow, or of red, white and blue. When wetted, the shading on the ribbon symbolizing the stripes in the fur of the tiger, Tippoo Sultan’s favourite emblem. The duke of Wellington’s medal (silver gilt), has the maze (or yellow as it is often termed) ribbon, and the medal was accordingly done, generally worn with this ribbon than with the red and blue one. There are also apparently occasional instances of it having been worn with a plain red ribbon.

5. The “EGYPT” medal. Authorized, 1802. Obverse: A Sepoy holding the Union Flag in his right hand; in the background a camp. In exergue, in Persian: “This medal has been presented in commemoration of the defeat of the French Army in Egypt by the victorious and brave English Army.” Reverse: A British ship drawing from the water, the crew on the poop and deck, and four pyramids. In the exergue, MDCCC. This medal was only awarded to native officers and men of the small force of Bengal and Bombay troops which formed part of the expeditionary force sent to Egypt, the body of the Egyptian fleet being commanded by Admiral Abercromby’s ships in the battle of the Nile. The medal was in one size, 1-9 in. diameter, 2 in. wide, 4.5 mm thick, the weight of silver, 1.6 oz. For the first time in a medal, a copy of the medal to enable them to prepare similar ones. The Bombay Mint would not however appear to have been equal to the occasion, for the sample was returned to Calcutta with the request that 1,439 medals might be struck the same, the medal as was accordingly done, but all of these medals were made of silver, and so the medal went to the Bombay troops in all ranks alike. As in the case of the “Deccan” medal, Sepoys, who had volunteered for Egypt, were exempted from the duties levied on pilgrims. This medal was worn suspended from the neck by a yellow cord.
### MEDALS AND DECORATIONS

**Plate I.**

#### Wars of the French Revolution and Napoleon Eras

- **Army General Service:** 1793-1814
- **Navy General Service:** 1793-1809

#### First and Second Sikh Wars

- **Punjab:** 1849-1850
- **Sutlej:** 1845-1846
- **Afghanistan:** 1878-1879

#### Indian Mutiny, 1857-1858

- **Indian Mutiny:** 1857-1858

#### Russian War

- **Turkey in Asia:** 1854-1856
- **Chinese:** 1856-1858

#### Reconquest of the Sudan

- **Khedive's Star:** 1883
- **Khedive's Sudan:** 1897

*Image is a diagram of Medals and Decorations with specific dates and medals represented.*
### Wars of the French Revolution and Napoleon Eras

- **Navy Gold Medal, 1794.** 1794-1815.
- **Army Gold Medal and Cross, 1810.** 1809-14.
- **Waterloo, 1815.** 1815.
- **Navy General Service, 1848.** 1793-1846. Medal dated 1848 but authorised 1847.
- **Army General Service, 1848.** 1793-1814. Medal dated 1848 but authorised 1847. Exchequer date 1793-1814, but first operations for which awarded took place 1817.

### India. Awards by the Hon. East India Company

- **Seringapatam, 1801.** 1799.
- **Ghazni, 1847.** 1839. Shah Soojah's original award of 1839 was, after his death, carried out by H. R. I. Co., in 1847.
- **Military Ribbon of India, 1842.** 1844-45. 1888. The Medals worn with this Ribbon are: 'Jubilee,' 'Zuck, Ghazni,' 'Bani,' 'Afganistan' (First Afghan War), 1842; 'Cádiz,' 1843; 'Kabul, 1842,' (Second Afghan War), 1843; 'Krigs-Grund,' 1844; 'Kaisar-Kandahar Star,' (Second Afghan War).
- **Sutlej, 1845.** 1845-46.
- **Punjab, 1849.** 1849-50.

### India. Awards by the Crown

- **First India G.S., 1851.** 1799-1826. Date given is as in exchequer, but the first action for which the Medal was awarded did not take place until 1816. This Medal is often termed 'Army of India' Medal.
- **Second India G.S., 1854.** 1852-1895.
- **Indian Mutiny, 1858.** 1857-59.
- **Afghanistan, 1879.** 1878-80. Second Afghan War.
- **Third India G.S., 1895.** Since 1856. The award of March 1905 made the 3rd Class.

### Russian War

- **China, 1842.** 1841-42, 1857-60, 1900.
- **Crimes, 1843.** 1854-56.
- **Turkish Crimea, 1855.** 1854-56.
- **Baltic, 1856.** 1854-55.
- **New Zealand, 1869.** 1845-47, 1860-66.

### Northern Africa

- **Abyssinia, 1868.** 1867-69.
- **Egypt, 1882.** 1882-89.
- **Khedive's Star, 1883.** 1882-90.
- **Khedive's Sudan, 1897.** 1896-98, and since. Since the repudiation of the Sudan this Medal has become a decoration for the Egyptian Army. Last award Dec. 1894. Making the 3rd Class.
- **Queen's Sudan, 1899.** 1896-98.

**Note:** Date following Title is that of authorization of first award, those under Title are the year, or years, in which the operations for which the Medal was awarded took place.
6. The "RODRIGUES, BOURBON AND MAURITIUS" medal. Authorized, 1811. Obverse: A sepoy, holding in his right hand the British flag, in left a musket with bayonet fixed, stands with his left foot trampling a French eagle and standards; beside the figure are inscribed "Java" and "Paul 1811." Within a wreath, in Persian: "This medal was conferred in commemoration of the bravery and devotion exhibited by the Sepoys of the English Company in the capture of the islands of Rodrigues, Bourbon, and Mauritius in the year 1811."

The government of Bengal also suggested the consideration of the governments of Fort St George and Bombay, that correspondence with the Burne, and that of the intrepid British arms and military forces that effected the reduction of these islands in 1805-10.

This medal was awarded to the native troops of the Bengal Cavalry for distinguished bravery and courage in the battle of Hugli, near Calcutta, in which they captured the French fort on the 18th of May, 1811. After the capture of the fort, the British forces were stationed within the walls of the place, and the French, who had been taken prisoners, were allowed to return, but were afterward re-captured. The medal was given to the native troops who had participated in the battle.

On a special order of the Governor-General, in the summer of 1811, these medals were presented to the British troops in India, who had been engaged in the capture of the French fort of Fort St. George, in the island of Ceylon, on the 18th of May, 1811.

This medal was given to the British troops in India, who had been engaged in the capture of the French fort of Fort St. George, in the island of Ceylon, on the 18th of May, 1811.

The medal was given to the British troops in India, who had been engaged in the capture of the French fort of Fort St. George, in the island of Ceylon, on the 18th of May, 1811.

This medal was given to the British troops in India, who had been engaged in the capture of the French fort of Fort St. George, in the island of Ceylon, on the 18th of May, 1811.

This medal was given to the British troops in India, who had been engaged in the capture of the French fort of Fort St. George, in the island of Ceylon, on the 18th of May, 1811.

This medal was given to the British troops in India, who had been engaged in the capture of the French fort of Fort St. George, in the island of Ceylon, on the 18th of May, 1811.

This medal was given to the British troops in India, who had been engaged in the capture of the French fort of Fort St. George, in the island of Ceylon, on the 18th of May, 1811.

This medal was given to the British troops in India, who had been engaged in the capture of the French fort of Fort St. George, in the island of Ceylon, on the 18th of May, 1811.

This medal was given to the British troops in India, who had been engaged in the capture of the French fort of Fort St. George, in the island of Ceylon, on the 18th of May, 1811.

MEDAL

deserving of the approbation of the Lords Commissioners of the Admiralty, although I am not enabled to make a particular statement of their merits.” For this reason the medal was never awarded to Rear-Admiral B. C. Collingwood, fifth in command on the great day, to his brother, R. B. Collingwood, Captain of the Flagship "Trafalgar," and to Captain G. H. Foulkes of the "Davies." The only case of line of battle ships engaged. One captain however, who was not mentioned in despatches, succeeded in gaining the medal, by a tour de force eminently characteristic of the superb breed of naval officers with whom the Admiralty have graced the British Navy. When Collingwood was awarded the medal for St Vincent, where he commanded the Excellent," he flatly refused to receive it unless all the captains at the same time. For alluding to this latter precedent H. A. Suggs, who had been flag-captain to Bowyer in the "Barfleur." When Collingwood was awarded the medal for St Vincent, where he commanded the Excellent," he flatly refused to receive it unless the medals were also given to every officer engaged. Following, the same day, the death of the admiral, the commander-in-chief of the fleet, who had received the medal but not the cap, was also included in the award, "for his services both before and since, and for the great and wonderful exertions he made at the time of the action, in saving and getting off his ships." The record of the "Nelson" was found guilty by court martial of failure in duty, did not receive the medal. Several posthumous awards of the smaller medals were made to the relatives of officers who were either killed in action or died of wounds. These were the "Ajax," the "Juniper," the "Thunderer," the captains of those two ships being at the time of the action in England giving evidence at the court martial of Sir Robert Calder. In all, of the eighteen awards of the Navy Gold Medal, eight were for fleet actions (one of which was posthumously), seven for actions, one between line of battleships, six in which frigates were engaged, two for shore operations (in both cases the taking of islands from the Dutch), and lastly the re-capture of the "Hermione" by the British. The Navy Gold Medal is circular in form, and its size is not memorable, not only because it was the first time that the medal was awarded to a frigate captain, but also because it is the only case in which the medal was awarded for boat service pure and simple. The Davison's medal was conferred in only three cases on officers below the rank of post captain. These were Commander Mounsey of the "Boone Citoyenne," for the capture of the "Furieuse" and Lieutes. Fifold and Stockham, who at Trafalgar commanded respectively the "Nile" and "Bellerophon." Following the action, the medals were divided among these two officers. At the present day, the medals are presented to the three men who were engaged in the battle of Trafalgar, and who have been awarded the medal. The navy medals worn by the recipient of the medal were presented by a private individual. The Gold Medal given by George III. to the superior officers in command at the battle of Trafalgar, in Sicily, on the 4th of July 1806 is an award of special interest, for not only was it the first military award made by the Crown during the reign, but it was moreover the prototype of the superb army gold medals and crosses which were so widely distributed during the years that followed. A general order of the duke of York, commander-in-chief, dated Horse Guards, 22nd of February 1806, awarded a gold medal for Maida to Sir John Stuart, K.B., his three brigadiers, and nine other officers. Subsequently four other officers were awarded this medal, and all but one of the recipients received the award. It was prescribed that the medal should be worn suspended by a Riband of the colour of the Sash, with a blue edge, from a button of the coat on the left side." It was in fact to be worn in the same way as the small Navy Gold Medal, and as this grant established blue and white as the specific navy ribbon, so did the Maida award establish red with a blue border as the regulation military ribbon. The Maida ribbon is in fact precisely the same as the Waterloo ribbon shown in Plate I. The Maida medal was 1.5 in. in diameter and struck in gold only. It was issued precisely alike, quite irrespective of rank, to each of its seventeen recipients.

Obverse: Head of George III., laureated and facing left, with below the legend: GEORGIUS TERTIUS REX. Reverse: Britannia casting a spear with her right hand, and on her left arm the Union shield, above, and approaching her is a Flying Victory holding out a wreath. In front of Britannia in four lines, is MAI/DA/IV/MDCCCVII; behind her the triqueta or trinacria, the symbol of the Island of Sicily. In the exergue are crossed spears.

Two and a half years after the Maida award the king authorized the "Army Gold Medal," the first grant of which was notified by the commander-in-chief, in a Horse Guards general order dated 6th March, 1807, that "the medal may be authorized and granted with the bestowal of the medal on 107 senior officers mentioned by name. The battles commemorated were Roleia, Vimiera (1808), the cavalry actions of Sahagun and Benevente (1808), Coruna and Talavera (1809). The Army Gold Medal so awarded was in two sizes, large, 2.1 in. in diameter, for general officers, small, 1.3 in. in diameter, for officers of lower rank: and the regulations provided that it should be worn from a red ribbon edged with blue, the larger round the neck, the smaller on the left breast from a button-hole of the uniform. The ribbon was the same width, 1.2 for both ribbons, and precisely the same later on for the Gold Cross. Both large and small medals were of identical design, in fact there was no difference, either in medals or in ribbons, except in size and the style in which they were worn."

Obverse: Britannia seated on a globe, holding in her right hand a laurel wreath, and in her left, which rests upon a Union shield, a sword, and upon the globe an eagle with broad wings. Reverse: A wreath of laurel, enwrapping the name of the battle or operations for which the medal was granted.

In the following years subsequent orders similar to the original grant extended the award of the Army Gold Medal, until eventually twenty-four distinct awards were made, commemorating twenty-six actions, or series of operations, which took place not only in the Peninsula, but also in North America, and both the East and the West Indies.

The Peninsula medals were for Roleia and Vimiera, Sahagun and Benevente, Coruna, Talavera, Busaco, Barrosa, Fuentes d'Oñor, Albuera, Ciudad Rodrigo (1812), Badajoz (1812).
Salamanca, Vittoria, Pyrenees, St Sebastian, Nivelle, Nive, Orthes, Toulouse. The West Indies medals were for Martinique (Feb. 1809) and Gaudeloupe (Jan.–Feb. 1810), the North American for Fort Detroit (Aug. 16, 1812), Chateaugay (Oct. 26, 1813) and Chlyster's Farm (Nov. 11, 1813), and there was, lastly, a medal awarded for Java (Aug.–Sept. 1811).

From the above it will be seen that as time went on many officers became entitled to two, three and even more medals, and as this was found inconvenient, the method of granting the award was very materially amended as notified by the commander-in-chief, in a general order, dated Horse Guards, October 7, 1813. This order formulated regulations which were as follows:

1. That one medal only was to be borne by each officer recommended for the distinction.
2. That for a second and a third action a gold clasp was to be attached to the ribbon from which the medal was suspended inscribed with the name of the action.
3. When a fourth distinction was earned, the medal and two clasps were to be replaced by a Gold Cross having the four actions for which it was awarded inscribed upon it, one upon each arm.
4. On every occasion the recipient was awarded the decoration after the fourth a Gold Clasp worn on the ribbon was added to the Cross.

The regulations further laid down that only officers should be recommended who had been "personally and particularly engaged" on the occasion, and that officers were to be named by special selection and report of the Commander of the Forces upon the spot, as having merited the distinction by conspicuous service. Further, the Commander of the Forces was empowered, in his selection to General Officers, C.O. of Brigades, C.O. of Artillery or Engineers, and certain staff officers holding field rank, and Commanding Officers of Units, and Officers succeeding to such command during an engagement.

It was also ordered that awards earned by deceased officers should be transmitted to their respective families. The Gold Cross that was, under these regulations, instituted is as follows:

A Maltese Cross, 1½ inches square, with an ornamental border; in the centre, a lion, facing right; in each limb of the cross the name of one of the actions for which it was conferred. The back of the cross is the same as the front. The cross was precisely the same irrespective of whether it replaced a large or a small medal. The clasps were all of the same pattern, whether worn with the cross, the large gold medal, or the small gold medal. They are 2 in. in length by ½ in. in width, and bear, within a border of laurel, the name of the action for which they were conferred. At the close of the war in the Peninsula the issue of this handsome and much coveted decoration was discontinued, the enlargement of the Order of the Bath (January 1815) affording another method of reward which the Crown deemed more appropriate.

On the occasion of this extension all officers who had obtained the cross with one clasp, i.e., who had been decorated for five or more actions, were made Knights Commander of the Bath. In all 847 awards of this superb decoration were made. The medal alone went to 469 officers, whilst 143 received it with one clasp, and 72 with two clasps. The cross was issued singly in 61 cases, with one clasp in 46, with two in 18, with three in 17, with four in 8, and with five clasps in 7 cases. The cross with six clasps was gained by Sir Colin Campbell (Lord Clyde), Sir Alexander Dickson (d. 1840) and Sir George Murray (d. 1846). Two officers, Viscount Beresford and Sir Denis Pack (d. 1823) received it with seven clasps. The Duke of Wellington's had nine, the decoration therefore commemorating fourteen out of the twenty-six battles, sieges or operations for which the Gold Medals, Cross and Clasps were awarded. On the limbs of this cross are, ROLAY AND VMIERA, TALAYERA, BUSACO, FUENTES DE ONOR. The clasps are for CIUDAD RODIGO, BADAJOZ, SALAMANCA, VITTORIA, PYRENEES, NIVELLE, NIVE, ORTHES and TOULOUSE. Not until 1850 did Captain Sayers of the royal navy, who commanded the "Leda" 36, and landed in command of the 500 seamen who erected and manned the batteries for the attack of Fort Corelins, received the small medal for Java. This is the only case of the Army Gold Medal having been conferred on a naval officer.

after the close of the Great War, however, do we meet with the real prototype of the war medal as we know it to-day; for the Waterloo Medal of 1815 is the first actual "general" medal that was ever issued, because it was issued precisely alike to all ranks. In the twelve cases in which we have seen that a medal was given to all ranks, the medals differed either in size or in metal, or in both, according to the rank of the recipient, and in eight out of the nine issued by the Hon. East India Company the award was withheld from the British officers and men employed. Again in none of the cases quoted were the awards made by the Crown. The "Dunbar" medal was awarded by the Commonwealth parliament. The men of the Nile and Trafalgar wore their medals through the generosity of private individuals. In the other nine cases the award was made by the directors of the Hon. East India Company. It was with the issue of the Waterloo Medal that all this was changed and for this well-merited and much prized boon the Services owe all gratitude to the duke of Wellington. Writing from Orville on June 28, 1815, to H.R.H. the dukes of York, he says:

"I would likewise beg leave to suggest to your Royal Highness (the then Commander-in-chief) the expediency of giving to the non-commissioned officers and soldiers engaged in the battle of Waterloo, a medal. I am convinced it would have the best effect in the army; and, if that battle should settle our concerns, they will well deserve it."

Again, writing from Paris, Sept. 17, 1815, to Lord Bathurst, then war secretary:

"I have been long intended to write you about the medal for Waterloo. I recommend that we should all have the same medal, hung to the same ribbon as that now used with the medals." (i.e. the army gold medals and crosses). It is also fair to point out that in his place in the House of Commons, and on the day after the duke's letter to the commander-in-chief had been penned, William Watkins Wynn urged that medals should be given to the survivors of Waterloo, and that they should be the same for both officers and men, "so that they who had been fellows in danger might bear the same badge of honour." And so came into being that type of "general" medal, which beginning with Waterloo has continued down to the present.

The description of these later medals, and the points of interest about them, will now be given as fully as exiguities of space will allow.

1. Waterloo, 1815.—Awarded by the Prince Regent, 1816. Obverse: Bust of the Prince Regent, Leg. GEORGE P. REGENT. Reverse: Figure of Victory seated; in her right hand, a palm branch; in her left, an olive branch. Above, WELLINGTON; below, WATERLOO, JUNE 18, 1815. Ribbon: Crimson with blue borders (Plate I). Clasps: Nil.

This award was made in a memorandum by H.R.H. the commander-in-chief, dated Horse Guards, March 10, 1816, and it is worth noting that the prince regent commanded that the ribbon "shall never be worn but with the medal suspended to it." The medal was conferred on all the British troops, including the King's German Legion, present on the 16th June at Quatre Bras, on the 17th in the fighting that took place during the retirement through Genappe to Waterloo, and on the 18th at Waterloo. It was also given to four regiments, 2nd Batt. 55th, 1st Batt. 54th, 2nd Batt. 74th, 1st Batt. 95th, and to six officers of General Colville's Brigade, which was detached. The reverse of this medal would appear to have been copied from the Greek Coin of Elis, about 450 B.C., a specimen of which is in the British Museum. The medals most prized by collectors are those of the 1st, 2nd, and 6th Dragons (6th Dragoons General brigade), and the 28th and 42nd Regiments of Foot, as those regiments suffered very severely and consequently fewer survivors received the medal than in other corps.

2. Ghuznee, 1839.—Awarded by the Government of India, 1842. Obverse: Elephant Gateway of the Fortres... Below, GHUZNEE, Reverse: In centre a space for name of recipient; above, 23rd July; below, a mural crown with underneath it 1839; the whole within a wreath of laurel. Ribbon: Particoloured, crimson and green (Plate I). Clasps: Nil.

This medal originated with Shah Soojah, whose part the Indian government took in the Afghan troubles of the time. His downfall and death having taken place before the medals were ready, the actual award was made by the Government of India. It was originally ordered (Bengal Military Proceedings, May 27, 1842; Nos. 151 and 152) that the ribbon should be green and yellow, and it was undoubtedly so worn by some recipients; but there is no official record to show why the colours were altered to green and crimson.
MEDAL

The medal was awarded to all troops both of the Crown and of the Company that were actually present at the siege and capture of the fortress, July 21, 22, and 23, 1839.

3. Syria, 1840.—Awarded by the Sultan of Turkey, 1841. Obverse: A figure of the Virgin Mary, in a Turkish dress, is flying, and above six stars; below, in Turkish, "The People of Syria; and the Citadel of Acre, A.H. 1258." Reverse: Cypher of the Sultan, within a laurel wreath. Ribbon: Red with white edges. Clasps: Nil.

The medal, thus globular in shape, was awarded to the officers and men of the British fleet that were engaged in the operations off the coast of Syria, against Mehmet Ali, which culminated in the bombardment and capture of St Jean d'Acre, Nov. 3, 1840. The medal was only struck in small numbers, in pure Turkish silver, although a few artillery and engineering officers doing duty in the fleet received it. It was given in gold to officers of flag rank and captains (or field officers), in silver to quarter-deck and warrant officers, and to the rest of the crew as in the case of the "Surma" medal. This is the only instance of there being a difference made according to the rank of the recipient since the "Surma" medal.

4. China, 1840-42 (1st Medal); China, 1857-60 (2nd Medal).—Awarded for the capture of Nanking, 1842, by the naval and military forces, both of the Crown and of the Hon. East India Company, that took part in the first China War, 1840-42. Another medal was struck, and is to be found in proof, but it was never issued as it was deemed it might give offence to China. This is the same medal as above, but the reverse has the under the same motto, the British lion trampling upon the Chinese dragon, and in the exergue, NANKING 1842. The second China medal was similarly awarded to both the naval and military forces, British and Indian, that took part in the second China war, 1857-60, to those, however, who were already in possession of the first China medal, the second medal was not awarded, they receiving a clasp CHINA 1842 to go on their original medal, together of course with the clasp to the system of the medal worn by the wrong arms. This medal was the second medal in fact not a new decoration but a re-issue. The first China medal was the first to be issued with the effigy of Queen Victoria upon it. The first medal with clasps for the second China war was struck in 1844. It was of iron, the Royal Marine Artilleryman, and it is now in the Cheshamese collection. Medals specially awarded by the Company to officers on Service in China, October 14, 1842, Lord Ellenborough, governor-general of India, dated Simla, are granted. The first medal is a crown and lion on a blue ribbon. The second medal is a crown and lion on a blue and yellow ribbon.

5. India, 1845-46. —Awarded by the Honourable East India Company, for the capture of Ferozeshuhur, 1846. Reverse: Head of Queen Victoria, as on First China Medal. Obverse: Reverse: Head of Queen Victoria as on First China Medal. Medals were also struck in the following years:

6. India, 1845-46. —Awarded by the Honourable East India Company, for the capture of Ferozeshuhur, 1846. Reverse: Head of Queen Victoria as on First China Medal. Obverse: Reverse: Head of Queen Victoria as on First China Medal. Medals were also struck in the following years:

7. Kelat-i-Ghilzie, 1842.—Awarded by Government of India, 1842. Obverse: A shield inscribed KELAT I GHILZIE encircled by a laurel wreath, and surmounted by a mural crown. Reverse: Another medal, in bronze, was struck at Khichhine on Peshawur in the year 1842 and the reverse showing the capture of Ghurza, and then joined hands with the column under Major-General Pollock at Cabul. The medal with reverse 4 was struck at Khichhine on Peshawur in the year 1842, and the reverse being on route by the victorious garrison at Jellalabad. This is the first of the four occasions on which the reverse of a medal has been used to denote the actual part taken in the operations by the respective regiments or companies. The reverse of this medal is also unusual in that the medals the one with the No. 1 reverse is the rarest, as its issue was confined to the small portion of his army that Major-General Nott left behind him in Candahar. The medal with the No. 2 reverse in Candahar was struck with a No. 1 reverse and was found in silver.

8. Sine, 1843.—Awarded by Queen Victoria to the forces of the Crown, and by the Government of India to the troops of the Company. Obverse: Head of Queen Victoria as on First China Medal. Reverse: CANDAHAR, 1843. Obverse: Another medal, in bronze, was struck at Khichhine on Peshawur in the year 1842, and the reverse showing the capture of Ghurza, and then joined hands with the column under Major-General Pollock at Cabul. The medal with reverse 4 was struck at Khichhine on Peshawur in the year 1842, and the reverse being on route by the victorious garrison at Jellalabad. This is the first of the four occasions on which the reverse of a medal has been used to denote the actual part taken in the operations by the respective regiments or companies. The reverse of this medal is also unusual in that the medals the one with the No. 1 reverse is the rarest, as its issue was confined to the small portion of his army that Major-General Nott left behind him in Candahar. The medal with the No. 2 reverse in Candahar was struck with a No. 1 reverse and was found in silver.

The award of a medal to the troops of the Crown and the Hon. East India Company engaged in the Gwalior Campaign of 1843 was first notified in governor-general's G.O., dated Camp, Gwalior Residency, January 4, 1844; and the Queen's permission for it to be worn by Crown troops given June 26, 1844. The force moved to Gwalior, the main base, on 30 January, 1844, and Sir Hugh Gough, the smaller under Major-General Gray. Each force fought an action on the same day, December 29, 1843, the former at Maharajpoor, the latter at Punniar, and the star was inscribed according to the order of the victory. The star was awarded by the Government of India, 1843, to each rank and file. The medals were manufactured from the marks of the captured guns. The star given to Sir Hugh Gough had in the centre a silver elephant in a line of silver and it was originally intended that all should be the same, but the silver star was substituted for reasons of economy. As there were few troops awarded the star it was a very rare and uncommon.

10. Sulej, 1843-46 (1st Sikh War).—Awarded by Government of India, 1845. Obverse: Head of Queen Victoria as on First China Medal. Reverse: No. 1. CANDAHAR 1845 within a laurel wreath; above, a crown. No. 2. GUZNEE CABUL 1845 both within a laurel wreath; above, a crown. Clasps: Royal military ribbon of India (Plate 1). Clasps: Nil.

The authority for this medal is a G.O. of the government-general dated Gwalior, 1845. It was struck at Khichhine on Peshawur in the year 1845, and the Hon. East India Company, which took part in the operations in Afghanistan in 1842, that is to say the second phase of the First Afghan War. The medal, with reverses 1, 2, and 3, was awarded to those who had been present at either Meeanee or Hyderabad, and the Hon. East India Company, which took part in the operations in Afghanistan in 1842, that is to say the second phase of the First Afghan War. The medal, with reverses 1, 2, and 3, was awarded to those who had been present at either Meeanee or Hyderabad. The medals the one with the No. 1 reverse is the rarest, as its issue was not only the smallest of the three, but it is also the only one that was not presented in the form of a medal.
This award, given to all the troops, both Crown and Hon. East India Company engaged in the First Sikh War, was first notified in governor-general’s G.O., dated Camp, Ferozepore, December 25, 1845, the queen’s consent for Crown troops to receive the medal being given on the same date. At a much later date, 1876, the Government of India issued the medals to the survivors of troops engaged in this campaign, the medal is not a very rare one, but a very rare combination is the medal with Ferrozesahur in the exergue and the clasp for Alival, as only half a company of native artillery was entitled to this clasp. As a matter of fact the clasp is a noticeably scarce medal, for it is the first time that “clasp” was issued with a “general” medal, the precedent followed being that of the Army Gold Medal. For every action after its first battle, which resulted in the award of medals, there were clasp medals awarded. Thus a medal with “Moodkee” in the exergue might carry one, two or three clasps; a “Sobraon” medal could have no clasps. This and the “Punjab” medal, to be described later, are generally considered to be the two finest pieces of medal work by W. Wyon, R.A.

This combination is particularly interesting as the clasp for Sobraon was given to all the men engaged in the action and therefore was awarded to the whole army, whereas in other cases, medals were issued to officers and clasp medals awarded to men. The clasp was not used with clasps for the Royal Army and Navy, and in the case of the British Army, it was never intended that any man should receive more than one clasp, but in 1845 the clasp was granted to all those who had participated in the battles of Sobraon. It is therefore not very surprising that the clasp is not very rare.

1. NAVY GENERAL MEDAL, 1793–1840.—Awarded by Queen Victoria, 1847. Obverse: Head of Queen Victoria as on First China Medal; under, “Naval General Medal” in small capitals. The date “1793” below the head in two lines, the name “VICTORIA” above in large capitals. Crown. Reverse: The date “1793” below in two lines, the name “VICTORIA” above in large capitals. Crown.

The obverse of this medal is inscribed “Naval General Medal,” while the reverse bears “1793,” indicating that it was awarded in 1793. The medal is designed with the head of Queen Victoria and the date “1793” below, along with her name “VICTORIA” in large capitals. The reverse also features the date “1793” and her name again. This medal is considered to be quite rare, as it was only awarded to naval personnel and later retired officers.

2. MEDAL, 1847–1851.—Awarded by Queen Victoria, 1847. Obverse: Two figures of Victory, one holding a palm and the other a shield, with the date “1847–1851” below. Reverse: A figure of Justice, with the date “1847–1851” below. Crown.

The obverse of this medal features two figures of Victory, one holding a palm and the other a shield, with the dates “1847–1851” beneath them. The reverse depicts a figure of Justice, with the same dates. This medal was awarded to officers who served with distinction in the Punjab campaign, and it is considered to be quite rare.

The obverse of this medal shows a crowned lion with the dates “1857–1860” below. The reverse features a crowned shield with the same dates. This medal was awarded to officers who served in the Indian Mutiny, and it is considered to be quite rare.

The obverse of this medal displays a crowned lion with the dates “1860–1862” below. The reverse shows a crowned shield with the same dates. This medal was awarded to officers who served in the Indian Mutiny, and it is considered to be quite rare.

The obverse of this medal features a crowned lion with the dates “1862–1863” below. The reverse shows a crowned shield with the same dates. This medal was awarded to officers who served in the Indian Mutiny, and it is considered to be quite rare.

The obverse of this medal displays a crowned lion with the dates “1863–1864” below. The reverse features a crowned shield with the same dates. This medal was awarded to officers who served in the Indian Mutiny, and it is considered to be quite rare.
DEIG, NEPAUL, KIRKE, POONA, KIRKHE-POONA; SEETABULDEE, NAGPORE, SEETABULDEE--NAGPORE; MAHEIDPOOR, CORYGAU, AVA, BURHPTOUR.

This medal was awarded "to the surviving officers and soldiers of the crown and of the East India Company" who took part in any one of seventeen specified actions and operations which occurred in India, Nepal and Burma, during the first twenty-five years of the 19th century, "including the officers and seamen of the Royal Navy and the Company's Marine who took part in the East Indies and China War." The announcement to the grant of this medal was announced in the London Gazette by a Notice of the Court of Directors, dated March 21, 1851. It was subsequently notified to the British Army by a Horse Guards G.O., dated March 21, 1851; to the Royal Mail and the Post Office, dated April 16, 1851. In this medal there is a discrepancy in dating, for though it is dated 1799-1801, the first action for which it was awarded, the storming of the fort of Ava, had occurred during the year of 1850. The medals were issued without clasps, the largest combination of clasps known being five. According to the India Office records there were apparently men entitled to as many as seven clasps, but whether any medal was issued with more than five is very doubtful. The first medal to the Duke of Wellington had three clasps, "Assaye," "Argaum," and "Gawilghur." With the exception of medals issued with the Ava and Bhurtpoor clasps, this medal is a rare one, with only a large number of the clasps, all except perhaps those in the "Assaye," "Argaum," which was issued to only two Europeans, and "Corygaum," as only two Europeans and two natives are known to have received it. "Defence of Delhi" is also a very rare clasp, as the greatest number of men to whom this clasp was awarded was 21, as is the "Corygaum," which was issued to only two Europeans, and thirty-five natives. The only European troops present at Corygaum were an officer and twenty-six men of the Madras Artillery, of whom one and two men respectively were awarded clasps. In the Burmese War, the Burma medal had already been given to the Company's native officers and soldiers for the First Burmese War, only the European officers and men of the Company's service received the medal with the Ava clasp; but as the Company's officers and men of the native armies were engaged in the same operations, they were entitled to the same clasp. A Burmese native, who actually served "within the hills," the medal with clasp "Nepal" was granted to those native troopers who had not received the Nepal medal, as well as to all the Company's Europeans of that rank.

15. India, 1852-55 (2nd India G.S., officially styled "India 1854").—Awarded by the Government of India as far as the first two issues with their clasps are concerned, all subsequent issues and clasps are those of the Court of Directors. Overhead: Head of Queen Victoria as in First China Medal. Reverse: Victory sitting, crowning a naked warrior sitting. In exergue, a lotus flower standing, with a large number of clasps, all except perhaps those in "Ribbon:" Red, with two blue stripes, forming five 1-inch stripes (Plate 1.). Clasps: PEGU, PERSIA, NORTH-WEST FRONTIER, UMBELAY, BHOUTAN, LOOSHAI, PERAK 1875-76; JOWAKI, NATUN, SAMANA 1880-81, BURMA 1881-82; HAZARA, BURMA 1880-81, MIAUWA 1880-81, LOOSHAI 1880-81, SAMANA 1881, HAZARA 1881, N.E. FRONTIER 1881, HUNZA 1881, BURMA 1889-92, LUSAYH 1889-92, WAZIRISTAN 1894-95, CHIN HILLS 1892-93, KACHIN HILLS 1892-93; Colonial Office: W. India 1852-60, China, Japan 1855-60, S. India 1855-60; South Africa 1856-57, with the clasp "Persia," was awarded by the Court of Directors January 19, 1858, and sanctioned by the Queen in the same month. The first issue of the medal by the Crown was authorized April 15, 1859, with the clasps "North-West Frontier" and "Umbeya," the former covering various expeditions between 1849 and 1859, the latter the hard-fought Umbeya Campaign of the latter mentioned year. All subsequent issues of the award were made by Queen Victoria, with the exception of those that carried with them the clasp "North-West Frontier," of which it was awarded April 29, 1859, to the men who had served in the campaigns for which the clasp was issued. The clasp was not issued with more than two or three clasps are rare. Seven of them is the greatest number awarded with any one medal, and a clasp with this number, viz. "Umbeya, North-West Frontier," was not awarded in the 1879-80 campaign. The rarest of all the clasps is probably "Hunza 1891," as less than a thousand men were employed, and the majority of these were Cashmere Imperial Service Troops. No European troops received the clasps, "Looshai," "Naga 1879-80," or "Hunza 1891," though a very rare clasp received by Indian troops employed, the only Europeans being two companies of the 2nd Derbyshire Regiment. So also is "N.E. Frontier 1881," for the Manipur expedition for which this clasp was given about 3000 men were employed. The number of men employed on the King's Royal Rifle Corps. It was with the issue of this medal with the clasp "Burma 1885-87," that the precedent was set of awarding the medal and clasp in bronze to all authorized followers, a precedent that has been followed ever since. In exergue, 1853, in the exergue of the re-issued medal, the place of the date is taken by a trophy of four assegais and a Zulu shield. Ribbon: Orange watered, with two broad and two narrow blue stripes (Plate II.). Clasps: 1877-78, 1877-78, 1877-78, 1877-78.

The command of the queen that a medal should be awarded to the survivors of the forces that had been engaged in the first, second and third Zulu Wars. In 1880, the Viscount Hardinge, the commander-in-chief, in a G.O., dated Horse Guards, November 22, 1854. No clasps were issued with this medal. The medal was accorded only to the "regular forces" (including the Auxiliary Forces). A clasp was given to the men of the "Native and Kaffir War a Small Naval Brigade and a detachment of Royal Marines took part in the operations, and the survivors received the medal. The award of the re-issue was notified in a G.O. by the Duke of Marlborough, Viscount Abergavenny, to "be granted to Her Majesty's Imperial Forces, and to such of Her Majesty's Colonial Forces, European or Native, as were regularly organized and disciplined as combatants, whether raised by the Colonial Government or by the General Officer Commanding." In 1880, in Zulu War of 1879, the Royal Navy and Royal Marines had a part, and received the medal. The clasp issued with this medal was as noted above and record the year, or years, of service covering all the operations in which the recipient was engaged. No one received a medal with more than one clasp. The medal without a clasp was issued in 1880-81 and 1882-83. This medal was issued to the battalions of the 24th Foot, 42nd Foot and 60th Foot, from January to September 1879, but never crossed the border into Zululand.

17. Crimea, 1854-55.—Awarded by Queen Victoria, in 1854, as in the Crimea Medal. Overhead: Head of Queen Victoria as in First China Medal; below, Victory in the center. Reverse: Victory crowning a Roman soldier, who holds a sword in his right hand, and bears on his left arm a shield on which is the figure of a lion. On the left, CRIMEA; Ribbon: Light blue, in a double scroll. A clasp was being entitled "Crimea," "Balaklava, Inkermann, Sebastopol, AZOFF." This medal, awarded to all Services, was first notified by a commander-in-chief's G.O., dated December 15, 1854. The grant was sanctioned by the Queen on January 9, 1855—the day on which Sevastopol fell—"unless they shall have been engaged after that date in some expedition or operation against the enemy." This latter proviso applied in the main to the naval clasps "AZOFF," the period for which award was extended to the 22 of November. The clasps for this medal are very ornamental, being in the shape of oak leaves, ornamented with acorns. The Royal Navy and Royal Marines, besides the "Azoff" clasp, received the clasp "Balaklava," "Inkermann," and "Sebastopol." The Royal Navy and Royal Marines.
The largest number of clasps to any one medal is four. Certain non-combatants received the medal without a clasp.

This award, notified by Admiral Order, June 3, 1856, was granted to officers and men of the Baltic Fleet, to the Royal Navy, and to the French and Russian navies, as to such officers and Men of Her Majesty’s Army as were employed in the operations in the Baltic in the years 1854 and 1855. The medal is, of course, practically a naval one, but two officers and nine other ranks were added to the list of recipients of the medal employed in the expedition, especially at Bomarsund, and received it.

19. Turkish Crimea Medal.—Awarded by the Sultan, 1856. Obverse: A trophy composed of a field piece, a mortar, and an anchor, surrounded by a border composed of the inscription, “For the operation of the Crimea,” and having a map of the Crimea spread over the wheel and breech. Behind are the Turkish, British, French and Sardinian flags. The flag of the nation to which the recipient belonged is in the front with that of Turkey; the flags of the other two nationalities behind. In exergue, “Crimea 1855,” “Crimea 1855,” or “La Crimee 1855,” according to whether the medal was intended for British, French or Sardinian recipients. Reverse: The Sultan’s cypher, below, in Turkish, "Crimea," and the year of the Hejira, 1271. Ribbon: Crimson watered, with bright green edges (Plate I.). Clasps: Nil.

This medal was distributed to all the Allied Forces, both naval and military, which shared in the operations in the Black Sea and the Crimea. It is known that of the British Forces in the Crimea, the medals was sunk, the remainder were issued indiscriminately, and a large number of the British received medals which were originally intended either for the French or Sardinians. The" in the exergue is, however, correctly written, and the medal is well known among the recipients of the medal.

This was the first notified in an Admiralty Notice dated, January 30, 1857. It was given to the crews of Her Majesty’s ships which were engaged in the expedition to Abyssinia, in the French Navy, and to such volunteers as accompanied those expeditions; also to those engaged in expeditions "equipped by the government and citizens of the United States:" also to the "concentration." It is only known that the medal was given to Her Majesty’s forces in the Crimea, but it is probable that it was given to the Royal Navy and Royal Marines by an Admiralty Order, dated June 3, 1869. Incompleteness in the returns many medals were issued without the reverse, which was not in existence at the time the medals were distributed. The dates on the reverse, in some cases, varied considerably, but it is known that the medal was issued to the French Army with one, and to the Navy with five different dates; for the Second Maori War, the medal was issued to the Army with twenty-one, and to the Navy with five different dates. No medal was dated 1856, but only of the Army of the medals bore date of a period covering that year, although no such medal was issued.

21. Indian Mutiny, 1857–59.—Awarded by the Government of India, 1858. Obverse: Head of Queen Victoria as on First China Medal. Reverse: Britannia standing facing left with a lion on her right, a sword and a shield. The right arm is the Union shield, and in her left hand a wreath. Above, INDIA. In exergue, 1857–1858. Ribbon: White, with two red stripes, forming five inch stripes (Plate I.). Clasps: DELHI (Plate II.), 1857–1858. of the First Expedition which terminated to Sep, 25, 1857; RELIEF OF LUCKNOW (Nov., 1857); LUCKNOW (March 2 to 21, 1858); CENTRAL INDIA (Jan. to June, 1858).

The grant of this award was first notified in a dispatch from the Court of Directors to the Government which stated that “the Queen has been graciously pleased to command that a Medal shall be granted to the troops in the Service of Her Majesty, and of the East India Company, employed in the suppression of the Mutiny in India.” This is the last medal given by the Honourable East India Company. The medal without clasp was awarded to all, including civilians, who had taken part in operations against the mutineers. The clasp was granted to those and of the numbers of those, during the five days of those actions, were engaged on the north of the Praj in maintaining and protecting the communications of the main army. In all, with and without the clasp, 21,256 medals were issued to the Forces in India and the Services. Over eighteen years later this same medal was reissued as a “general service” medal, the award being for operations in Central Africa, and on the East and West Coasts, during the period 1896–8, 1897–8, 1898–9, and 1899–1900.

1 These clasps were all naval awards, but two companies of the West India Regiment took part in the operations for which the clasp “Gambia, 1894,” was awarded.

2 The medal was awarded by the Admiral, to certain local forces which co-operated with the U.S. troops in the successful campaign.

3 Mwele, 1855, is not strictly speaking a clasp, as it is engraved on the edge of the medal. Recipients already in possession of the medal were entitled to have the clasp engraved thereon. It corresponds, however, to a clasp in that it commemorates a particular service, and so has been included.
Africa Medal" (see Army Order 253, of Dec. 1894) is somewhat of a misnomer, for very frequently the medal has been granted for services in Central Africa and in the Hinterland of the East Coast as well as for the operations in South Africa. In this connection, "Ashantee" medal, the clasp only was given to those who already had the medal, so subsequent issues do not make it a new award. As will be seen later, the same medal was subsequently issued with a clasp and reverse clasp which may or may not be described as a clasp badge that could be worn in conjunction with the older one. With the exception of those issued with "Mwele, 1895" engraished on the medal, none of these medals have been issued without a clasp since 1886. The first reverse clasp was issued in 1886 which with this medal was first awarded, and it is said that yellow and black (the Imperial Russian colours) were chosen as the colours of the ribbon, in compliment to his consort the grand duchess Marie of Russia.

28. Egypt, 1882-1889.—Awarded by Queen Victoria, 1882. Obverse: Head of Queen Victoria as in the West African Medal. Legend: VICTORIA REGINA ET IMPERATRIX. Reverse: A ship panned in Ice; above, an Arctic shell in the sky with the word "Ice" in the centre. (Plate I.) Clasps: ALEXANDRIA, 11th July; Tel-el-Kebir, 1882; El-Teb, Tamaa, El-Teb-Tamaa, The Nile, 1884-85. (Khedive, 1885-86, 3rd King, 1885-86, 2nd King, 1885-86, 1st King, 1885-86. ZAH, 1888; TOSKI, 1889. This medal was first awarded (Admiralty Circular, Oct. 1882; G.O. by the commander-in-chief, Oct. 17, 1882; and G.O. by governor-general of India, Oct. 27, 1882;) to the crews of Her Majesty's ships which took part in the operations between July 16, and Sep. 14, 1882. The first two clasps were also given with this issue. One military officer (Major-General Sir A.B. Tulloch, then of the Welsh Regiment) received the clasp "Alexandria, 11th July" as he was serving in the fleet as military advisor to Admiral Sir Beauchamp Seymour. A second issue was made in 1884, and with it the next four clasps were given; "Suklin, 1884," for those who landed at Suklin or Trinikat between Feb. 19 and March 26, 1884, was, however, ordered to be issued. Around 1882 medal, those not so possessed receiving the medal without a clasp. A third issue was made in 1885: the next five clasps were: Suklin, 1885; 1882-85; a fourth clasp was awarded to those who served south of Assouan on or before March 7, 1885; Suklin, 1885, to those who were engaged in the operations at Sukhna between March and May 14, 1885: but the former clasp was only for those who refused the medal only. The medal in slightly raised letters on a medallion with the inscription "The Nile, 1882-84," was the medal alone was also given to all on duty at Sukin between March 27, 1884, and May 14, 1885. No medals were issued with single clasps for "Toresk," recipients of which were not "V.C." or "K.T." and "K.C.M.G.," recipients of which got also clasp "The Nile, 1884-85." In 1886, the medal without was issued to those who had previously received it and had served at, and south of Wady Halfa, 1885-86, but no clasps were issued with this issue, although the operations included the battle of Ginni. The last issue was made in 1890. The medal with clasp "Gazimag, 1882-1886" to all who served in the second battle of that action near Sukin, Dec. 20, 1888: the medal alone to all employed on the Nile, Dec. 23, 1889. The medal with clasp "Korosko, 1889, and clasp "Toresk, 1889," to all present at that action, Aug. 3, 1889. Beside those already enumerated, there was a clasp to all employed on the Nile and the "Nile, 1889-90." Kandahar. At the conclusion of the first phase of the Second Afghan War, it was proposed that the (Second) India G.S. Medal should be issued for this campaign with clasps "Afghanistan," "All Musjid," "Peiwar Kotal," "Charasia, Kabul, Ahmed Khel, Kandahar," and grant a separate medal. The first official intimation of the award is in a telegram from the secretary of state for India to the viceroy, dated Aug. 7, 1880. The award, with the regulations to govern the grant, was promulgated by order in council on Dec. 16, 1880, and subsequent G.O.'s. The medal without clasp was awarded to all who had served across the frontier between Nov. 22, 1878, and May 26, 1879 (first phase of the war), and between July 23, 1879, and Aug. 5, 1880 for Southern Afghanistan (second phase of the war). The "Kabul" clasp was awarded to all who had shared in the operations at and near that place from the 10th to the 23rd Dec., 1879, including the column under the command of Brigadier-General C. J. S. Gough, C.B., which joined Sir Frederick Roberts on the 24th Dec., 1879. The clasp for "Kandahar" distinguished the whole garrison of the beleaguered city, but only the troops actually engaged in the operations under Sir Frederick Roberts' command against Sirdar Mahomed Ayub Khan on the 1st Sep., 1880. The greatest number of class medals were awarded for the operations against the Persians to which such medals were issued are the 72nd Highlanders, 5th Ghorkas, 5th Punjab Infantry and 23rd Punjab Pioneers. The bust of the Queen by Sir Edgar Boehm, R.A. has not been re-produced on any of the medals. The "Kabul" clasp was awarded to Queen Victoria, 1880. This decoration took the form of a five-pointed star, 1 inch across from point to point, with a ball between the points; between the ball and the point, the words "Kabul to Kandahar" were embossed on the medal for suspension. Obverse: In the centre the imperial monogram V.R.I., surrounded by a band inscribed KABUL TO KANDAHAR. Reverse: Plain, with a hollow centre, round which the reclining figure of the Queen is inscribed. Above, the word "Kabul," below the word "Kandahar," and round the edge, the word "KABUL TO KANDAHAR." This old rainbow-coloured military ribbon is worn with this star. The grant of this award was first notified in a despatch from the secretary of state for India to the viceroy, dated Nov. 30, 1880. This awarded the decoration "to the force which marched from Kabul to Kandahar," and later, Aug. 26, 1881, a G.O. by the Governor-General extended the grant "to the troops which then composed the garrison of Kelat-i-Ghilzai, and accompanied the force under the command of Lieutenant-General Sir F. S. Roberts, G.C.B., in the operations from Kabul to Kandahar."

1. Issued to the Royal Navy and Royal Marines only.
2. (Clasp not issued to Royal Navy and Royal Marines.)

### LONG SERVICE AND GOOD CONDUCT

- **Navy and Royal Marines, 1831:**
- **Army, 1833:** The "Meritorious Service" Medal is worn with a similar Ribbon.
- **Militia, 1894:**
- **Imperial Yeomanry, 1904:**
- **Hon. Artillery Company, Long Service Medal, 1906:**

---

Note: The date following the title is that of authorization of first award, those under titles are the year, or years, in which the operations for which the medal was awarded took place.
31. **Canada (General Service).**—Awarded, 1899. Obverse: Head of Queen Victoria, as in Third India G.S. Medal. Reverse: Within a wreath, the Dominion flag, above, CANADA. Ribbon: Red, with white centre (Plate I.). Clasps: FENIAN RAID, 1866-1868; DURBAN, 1878-79; EGYPT, 1882; RED RIVER, 1870. One battalion of the King's Royal Rifles received this medal with the Red River Clasp. Otherwise issue confined to Canadian forces.

32. **Queen's Sudan.** 1886-1898.—Awarded by Queen Victoria, to British officers and men of the Royal Horse Artillery, and other contingents, including non-commissioned officers and men of the Sudanese tribes. to the Royal African Company. Obverse: In the centre, the obverse impression of a clasp, above, the name of clasp, within a wreath, below the Empire's emblem, the Star of Nile, in a circle, to the right: DE LA SALLE. Reverse: A winged Victory, seated, with, on either hand, the Union Jack and the Egyptian flag. The left hand holds a laurel wreath, the right, a sword, the right hand of the former including the name of clasp, the latter, the word SYDNEY, and below this lotus leaves. Ribbon: Half black, half yellow, divided by a narrow red stripe. Clasp: none.

Given for the operations of the army and navy, and for the campaign of 1896-7

33. **Khedive's Sudan.** 1896-1900.—Awarded by the khedive in 1897. Obverse: Abbas Hilmi II., and date, in Arabic. Reverse: A clasp, with two narrow centres, on a tablet below "Recovery of the Sudan," in Arabic. Ribbon: Yellow, with blue centre (Plate I.). Clasps: FIKRET, HAFIR, SUDAN, 1897; SUDAN, 1898; ABU HAMED, THE ATBARA, KHAZIR, JIDBALLI, SUDAN, 1899; EGYPT, 1901, 1903; CEDID, BAHR-EL-GHAZAL, 1900-1902; THEROK, NYAM NYAM, TALODI.

This medal was awarded to officers and men of the British Navy and Army, to the Egyptian Army engaged in the reconquest of the Sudan. Those with the clasp were awarded a suitable title.

34. **Cape Colony General Service.** 1900.—Awarded by the government of Cape Colony. Obverse: Bust of Queen Victoria as on the Volunteer Long Service Medal. Reverse: Arms of Cape Colony. Ribbon: Blue, with narrow yellow edge (Plate I.). Clasps: BASUTOLAND, TRANSEK, BECHUANALAND. Issued to Colonial troops only, for services in various minor campaigns.

This medal was issued by a chartered company since the close of the Company's rule in India. It was awarded to British officers and men of the British service, to the Mounted Rifles, BechuanaLand police, and the Chartered Company's own forces, engaged in the first Matabeleland and Mashonaland Campaigns 1893, 1896, and 1897.

This medal only differs from the West African in that it has a different clasp, the clasp, dated 1894-96, implying the proclamation of the Anglo-Boer War, and the clasp, dated 1896-97, referring to the later expedition. It was awarded to local forces (and of course their British officers) received this medal. But a few officers and men of the Indian Army and of the Royal Navy have also received it.

This medal was awarded to local officers and also to officers and men of the Indian Army and Royal Navy.

38. **Ashanti Star, 1896.**—Awarded by Queen Victoria in 1896. Obverse: Portrait of the Ashanti King, Asante. Ribbon: Ashanti, 1896. Round it: Reverse: Inscribed from the Queen. The star is four-pointed, and is crossed by a saltire or St Andrew's cross. Ribbon: Yellow with black stripes (Plate II.).

This medal was issued for the expedition against Accra in 1896. As there was no actual fighting, no medal was given, but sickness claimed many victims, amongst them Prince Henry of Hesse. The decoration was issued to officers and men of the British Army engaged in the campaign.

39. **Ashanti Medal, 1900.**—Awarded by King Edward VII. in 1901. Obverse: Head and bust of King Edward VII. in the uniform of a field-marshal, by De Saulles. Reverse: a lion standing on a clasp, the obverse impression of a clasp, above, the name of clasp, below, Britannia, holding a shield, and black edges and black central stripe (Plate II.). Clasp: KUMASSI.

This medal was the first which was issued with an effigy of King Edward VII. It was given only to local forces, and the British officers and non-commissioned officers of the Naval volunteers, and the British and Indian Armies, and the (Wei-hai-Wei) Chinese Regiment, for operations during the Boxer rebellion.

This was the last war medal, as the "First China" was the first of the British medals to be awarded, and the Chinese who took part in the forming of the Tsien, the relief column, who had taken part in the former China War, received the new medal as well as the old.

40. **Africa General Service, 1899—.**—Awarded by King Edward VII. in 1902. Obverse: As in Ashanti Medal of 1900. Reverse: As in Uganda Medal above described. Ribbon: Yellow, with black edges and two narrow centres (Plate II.). Clasps: N. NIGERIA, with various dates; S. NIGERIA, with various dates; UGANDA, 1900; JUBALAND, GAMBIA, Lango, 1901 and 1902; JIBBALLI, KISSI, 1905; SOMALILAND, 1901 and 1902-04; BRITISH CENTRAL AFRICA, 1899-1900; ARO, 1901-02.

This medal represents an almost incessant warfare of a minor, but important, nature. Of the eighteen months, eleven clasps were awarded, some awards being of course retrospective. The clasp "Jubaland" is chiefly a naval award, but all the rest are almost exclusively earned by the West Africa Frontier Force and the Scottish Mounted Rifles. It is a justly merited and substantial recognition of the efforts of the troops in the Somaliland Campaign, within one year of the peace of Vereeniging, and received the medal and clasp. The "Somaliland, 1902-04" clasp commemorates the considerable campaign in which contingents from Great Britain and India took part.

41. **Queen's South African.** 1899-1902.—Awarded by King Edward VII. in 1901 shortly after Queen Victoria's death. Obverse: Portrait of the Queen, by De Saulles. Reverse: Britannia holding a long wreath in her right hand, and an African tablet in the background a coast line, the sea and war-ships. Ribbon: Centre orange bordered with blue, outside edges red (Plate II.). Clasp: none.

The "Queen's" medal for troops engaged in the South African War was authorized, shortly after Queen Victoria's death, by Army Order 94 of 1901. It was given "to all officers, warrant officers, non-commissioned officers, and men of the British, Indian, and South African forces, and to those members of the Royal Naval Reserve, who actually served in Africa between 11th of October 1899, and a date to be fixed hereafter" (the war not being concluded) "to all troops stationed in Cape Colony and Natal at the outbreak of hostilities in South Africa on the 8th of October 1899, and after the 8th of April 1900, and a date to be fixed hereafter."

The last provision showed a widening of the signification hitherto attaching to "war service," for the troops at St Helena were employed in guarding Boer prisoners, and others engaged in South Africa during October 1899, and April 1900, and others who actually served in Africa between 11th of October 1899, and a date to be fixed hereafter, were, in accordance with the terms of the award, general in character, to wit, SOUTH AFRICA, 1901 and SOUTH AFRICA, 1902.

42. **China.** 1900.—Awarded by King Edward VII. in 1902. Obverse: Portrait of Queen Victoria. Reverse: As in Ashanti Medal of 1900. Clasps: DEFENCE OF LEGATIONS, RELIEF OF PEKIN, TAKU FORTS.

They were awarded to members of the Royal Navy (including some Naval volunteers), British and Indian Armies, and the (Wei-hai-Wei) Chinese Regiment, for operations during the Boxer rebellion.

The ribbon of this medal is perhaps more frequently seen than
that of any other British war medal except those for South Africa.

In 1903 the medal was re-issued with the military effigy of King Edward VII. (as on the Ashanti, 1900, medal) on the obverse, and the date was omitted from the reverse. The medal is issued in gold, silver, and bronze. See to follow.

47. India. 1908.—A New India General Service Medal was authorized in 1908, to take the place of the medal granted by A.O. 43 of 1903. This was to be issued in silver to officers and men of all ranks (except the non-commissioned officers of the mercantile marine serving in chartered tramp ships). It is a sort of general service medal, clasps being added as earned. Up to 1910 only the above clasps had been authorized.

48. Polar Medal (or Antarctic Medal).—Awarded by King Edward VII to officers of the mercantile marine serving in chartered tramp ships. Medals, Ribbons, and clasps are of the same kind as the India General Service or Transport Medal. Reverse: In the foreground a sledge and travelers, in the background the steamer "Discovery" (Capt. R. F. Scott’s Expedition, 1904). Ribbon: As for 1st and 2nd Arctic Medals, white, with an additional dark blue stripe. Clasps: Clasps for officers and men of the "Discovery," whether belonging to the Royal Navy or not. It is given with a dated clasp for Antarctic expedition service.

Other Medals and Decorations.—The above forty-nine medals are given as rewards for participating in the operations they commemorate, and issued generally to all concerned, irrespective of individual distinction or bravery. There are other classes of medals and decorations, civil as well as military, which must be grouped with them, as being allied in character. These are either (i) awards personal to the recipient, being an acknowledgment of or reward for special individual service or conduct these are civil as well as military in respect of awards for bravery), or (ii) awards that are simply of a commemorative kind, though worn as war medals and for the most part given to officers and soldiers. The more important of these two classes will be named. Orders given for service are dealt with, for the most part in the article KNIGHTHOOD; but particulars are given here of certain distinctly military orders that have no knighthood rights and duties, and indeed little meaning apart from the deeds or services which led to the award—being so to speak, records of the past, rather than badges of a present membership. Individual decorations for services may be classed as (i.) for gallantry, (ii.) for special merit, and (iii.) for long service and good conduct.

1. Indian Order of Merit.—Awarded by H.E.I. Company and notified by G.O. of governor-general, April 17, 1837. Obverse: 1st Class—A Gold Star, 1½ in. diameter; in the centre, on a gold ground, a wreath of laurel leaves, the name of the recipient being inscribed "FOR VALOUR." There is a bronze laured bar for suspension, connected with the cross by a V. The reverse is plain, but the name, rank and corps of the recipient are engraved on the back of the laured bar. Ribbon: Red for the army; blue for the navy; and green for the air force. It is a distinction of bravery a clasp, bearing the date of such act, may be awarded.

Nothing save " the merit of conspicuous bravery " gives claim for the decoration, and it must be evinced by " some signal act of valour or devotion to their country performed " in the presence of the enemy. (For full time of act abrogated, but soon restored to force.) The original Royal Warrant has been supplemented by various Royal Warrants (Oct. 1857, Aug. and Dec. 1858, Jan., April and Aug. 1851), and now every officer and man in the Regular Forces, British and Colonial, are eligible, with the single exception of native ranks of the Indian army, who have an equivalent decoration in their own Order of Merit. In the case of recipients who have already been awarded a pension, a pension of £10 a year, and an additional £5 a year for each clasp. A larger grant is sometimes given to holders of the V.C. who are in need of monetary help. In all, up to 1904, the Cross was awarded to 521 recipients (including 15 posthumous awards).—Instituted by Royal Warrant, September, 30, 1862. Obverse: A military trophy, with, in the centre, the Royal Arms in the Long Service and Good Conduct Medals. Reverse: Inscribed—FOR DISTINGUISHED CONDUCT IN THE FIELD (Army).—Instituted by Royal Warrant, 7th of February 1881, authorized award of clasps for subsequent acts of gallantry.

2. Albert Medal.—Awarded to distinguished conduct in the field in any part of the world entitled to this medal, and only non-commissioned officers and men of the British forces are eligible for the award. Prior to its institution, distinguished gallantry was rewarded by the King in the form of a "King’s Royal Warrant." Single clasps have been occasionally conferred, and there is more than one case of a recipient having earned two clasps to his medal. The decoration is awarded only to those who " have, in saving or endeavouring to save the lives of others from shipwreck or other perilous situation..." and are "commended in a warrant..." a distinction confined " to cases of extreme and heroic daring..." the 2nd for acts which, though great courage may be shown, " are not sufficiently distinguished to deserve..." the 1st Class of the decoration.

3. Victoria Cross.—Instituted by Royal Warrant, January 29, 1856. A bronze Maltese Cross, 1½ in. diameter, with, in the centre, the Royal Crown (lion and crown), and below it a scroll inscribed "FOR VALOUR." There is a bronze laured bar for suspension, connected with the cross by a V. The reverse is plain, but the name, rank and corps of the recipient are engraved on the back of the laured bar. Ribbon: Red for the army; blue for the navy; and green for the air force. It is a distinction of bravery a clasp, bearing the date of such act, may be awarded.

3. Albert Medal.—Awarded to distinguished conduct in the field in any part of the world entitled to this medal, and only non-commissioned officers and men of the British forces are eligible for the award. Prior to its institution, distinguished gallantry was rewarded by the King in the form of a "King’s Royal Warrant." Single clasps have been occasionally conferred, and there is more than one case of a recipient having earned two clasps to his medal. The decoration is awarded only to those who " have, in saving or endeavouring to save the lives of others from shipwreck or other perilous situation..." and are "commended in a warrant..." a distinction confined " to cases of extreme and heroic daring..." the 2nd for acts which, though great courage may be shown, " are not sufficiently distinguished to deserve..." the 1st Class of the decoration.

4. Albert Medal (for saving life at sea).—Instituted by Royal Warrant, 7th of March 1866. Gold oval badge, enamelled in dark blue and gold, consisting of a crown, surmounted by a wreath of laurel leaves, the whole encircled with an anchor erect, all in gold, surrounded with a garter in blue, inscribed in raised letters of gold " FOR GALLANTRY IN SAVING LIFE AT SEA," and surmounted by a representation of the sovereign of the crown of the prince consort, the whole edges with gold. Ribbon: dark blue, with two white stripes. Clasps are awarded for any subsequent acts of bravery. By a subsequent Royal Warrant of the 12th of April 1887, the decoration was re-constituted as the Albert Medal for Conspicuous Gallantry. It is already described. Ribbon: Dark blue, with four white stripes (½ in. wide). Clasps: As authorized in original warrant. 2nd Class—Badge exactly similar to that of the 1st Class, except that it is entirely worked in bronze, instead of gold and bronze. Ribbon: Dark blue, with two white stripes. Clasps: As authorized for 1st Class.

The decoration is awarded only to those " who have, in saving or endeavouring to save the lives of others from shipwreck or other perilous situation..." and are "commended in a warrant..." a distinction confined " to cases of extreme and heroic daring..." the 2nd for acts which, though great courage may be shown, " are not sufficiently distinguished to deserve..." the 1st Class of the decoration.

5. New Zealand Cross.—Instituted by an Order of the governor of New Zealand in council, 10th of March, 1869. Silver Maltese Cross with gold star on each of the four limbs and in the centre, in a circle within a gold laurel wreath, NEW ZEALAND. Above a wreath is a scroll containing the words " King's Royal Warrant," and below a silver bar ornamented with laurel in gold. The name of the recipient is engraved on reverse. Width of Cross, 1½ in. Ribbon: Crimson. Clasps: Authorized for subsequent acts of valour. In authorizing this decoration Sir G. F. Bowen, the then governor, went outside the council in council and intimated " Her gracious desire that the arrangements made by it may be considered as established from that date by Her direct authority." It was, however, stipulated that the occasion must be " such as to form precedent." The gold badge is the one worn by " who may particularly distinguish themselves by their bravery in action, or devotion to their duty while on service," and only local " Militia, Volunteers or Armed Constabulary " to be eligible for it. Seventeen of these decorations were awarded, and 13 clasps were awarded.

To reward " acts of pre-eminent bravery in Action with the Enemy."

Firstly petty officers and seamen of the Royal Navy,

1 Now naval effigy of King Edward VII., as on Transport Service Medal.
and non-commissioned officers and privates of the Royal Marines, are eligible for this decoration. Prior to the institution of this decoration, acts of gallantry by sailors and marines were rewarded by the same medal as that given to the army before the "medal for military acts of courage" or "Medal for Meritorious Service" as the case may be. If the holder be a Chief or First Class Petty Officer, or a Sergeant of Marines, the award carries with it an annuity of £20 per annum; and if a recruit's service ends before the end of the term of that period, he may receive a gratuity of £20 on discharge.

7. Albert Medal (for saving life on land).—Instituted by Royal Warrant, 30th of April 1877. 1st Class—Similar to that of the 1st Class for saving life at sea, but the enamelling is in red instead of blue, and there is no anchor interlaced with the monogram V.A. Ribbon: Crimson, with four white stripes. Clasps: for subsequent acts of same character. 2nd Class—Badge similar to that of the 2nd Class for saving life at sea, but the enamelling is in red instead of blue, and there is no anchor interlaced with the monogram V.A. Ribbon: Crimson, with two white stripes. Clasps: As authorized for 1st Class.

The conditions governing the award of this decoration are the same that govern the award for saving life at sea. Originally the award was restricted to acts of gallantry performed within British dominions, but this restriction was removed by Royal Warrant, 5th of June 1908.

8. Distinguished Conduct in the Field (Colonial).—Instituted by a Royal Warrant, 24th of May 1894, which was later cancelled and superseded by Royal Warrant, 31st of May 1895. Obverse: same as "Distinguished Conduct in the Field" (Army). Reverse: same as "Distinguished Conduct in the Field" (Army). Three stripes equal width, outside white, centre blue. Clasps: none authorized.

This award is to recognize "Distinguished Conduct before the Enemy." Its grant is confined to "Warrant Officers or Sub-ordinates in the Royal Marines, who, in the course of their duty or in private capacities, have performed acts of gallantry, not done in the line of duty," and are not entitled to the "Conspicuous Gallantry" Medal; also, they, "by reason of not holding a commission in the Royal Navy, are not eligible to any existing Order or Decoration.

10. Edward Medal.—Founded in 1907 to reward acts of courage in saving life on land. It was instituted by Royal Warrant, 3rd December 1906 (R.W. Dec. 3) so as to be awarded "to those who, in the course of industrial employment endanger their own lives in saving or endeavouring to save the lives of others from perils incurred in connexion with such employment."

Certain important medals and decorations for saving life are not the gift of the Crown. These are allowed to be worn in uniform on the right breast. They are the medals of the Royal Humane Society, those given by the Board of Trade for gallantry in saving life at sea, the medals of the Royal National Lifeboat Institution, those of the Shipwrecked Fishermen and Mariners’ Royal Benevolent Society, Lloyd’s Honorary Silver Medal, Liverpool Shipwrecked and Humane Society’s Medals, and the Stanhope Gold Medal.

All these are suspended from a dark blue ribbon with the exception of the medals of the S.F. and M. Royal Benevolent Society, which has a red ribbon and the crossed gold and silver dollars in gold, in a broad dark blue centre, edged with yellow, and black borders. These medals are usually struck in silver or bronze, but occasionally gold medals are awarded. The Stanhope Gold Medal is annually awarded to the gallant men of all the acts of rescue for which the society have awarded medals during the year. This award has been frequently earned by officers or men of the Royal Navy. It is, in fact, the "Vicoria Cross" of awards of this character.

The following are decorations for special merit:

1. Order of British India.—Instituted by General Order of Governor-General of India, 17th of April 1837. 1st Class—A gold star of eight points radiated, 1½ in. in diameter, between the points a crown of five rays, in the centre, a device of the sun in gold, on a ground of light blue enamel, a gold lion statant, within a band of dark blue enamel, containing in gold letters ORDER OF BRITISH INDIA, the whole encircled by a gold laurel wreath. The whole hangs from the ribbon by a gold loop attached by a ring to the top of the crown, and is worn round the neck, outside the uniform. Ribbon: originally sky-blue, changed to crimson 1838. 2nd Class—Gold star similar to that of the 1st Class, but smaller, ¾ in. diameter, and without the crown. The centre also is similar to that of the 1st Class star, but the enamelling is all dark blue. Suspended and worn as in the 1st Class. Ribbon: As in 1st Class.

This, the highest military distinction to which in the ordinary course of their duty, officers of the Royal Marines may be entitled, besides the Victoria Cross to which qualification, in addition to those already mentioned, entitles them, is a reward for long, honourable and specially meritorious service. The 1st Class is composed exclusively of officers of and above the rank of Subedar in the artillery and infantry, or of 2nd Class Petty Officer in the marine department. For every year of service after the expiration of the 14th year of service, to which them, is a reward for long, honourable and specially meritorious service. The 2nd Class is open to all native commissioned officers, irrespective of their rank. Originally the order was limited to 100 in the 1st Class and the same number in the 2nd, but it now comprises 150 in the 1st Class and 100 in the 2nd Class. By Royal Warrant, 31st of May 1895, the 1st Class are entitled to the title of "Sirdar Bahadur," and receive a daily allowance of two rupees in addition to the pay, allowances or pension of their rank, while those of the 2nd Class are styled "Bahadur," and receive only extra "Ability and Good Conduct."—Instituted in 1842. Obverse: A paddle-wheel steamship. Reverse: Crown and anchor, and inscribed, FOR ABILITY AND GOOD CONDUCT. Ribbon: No authority for the appointment of officers.

8. The Distinguished Service Order (see Knighthood) is given only to officers (and naval and military officials of officer rank, not including Indian native officers) for services in war. Often it is the reward of actual conspicuous gallantry under fire, but its purpose, as defined in the Royal Warrant instituting the order, is to reward "individual instances of meritorious or distinguished service in war, and the same shall not be confined to those whose rank is so high as to render them eligible who have been mentioned in despatches for meritorious or distinguished service in the field, or before the enemy." In the main, therefore, it is awarded for special services in war, and not for save in the performance of a duty, and although recipients are a fact generally rendered in despatches, the order is in no sense a sort of second class of the Victoria Cross. Like the latter, the Distinguished Service Order is generally referred to by its initials.

5. The Royal Red Cross is also an Order. Membership is restricted to women (not necessarily British subjects), and is given as a reward for naval or military nursing service. Instituted 1883.

6. The Kaisar-i-Hind Medal is given for public services in India. 1887. The Volunteer Officers’ Decoration.—Instituted in 1892. An oval medallion with a silver cross, within the circle, the monogram V.R. and crown in gold. Worn from a ring. Ribbon: Dark green.

This decoration was instituted in 1892, and is the reward of twenty years and upwards of commissioned ranks of the volunteer force. It is generally called the "V.D."

1. Now naval effigy of King Edward VII, as on Transport Service Medal.
2. Other "Meritorious" or "Long Service" medals worn with a crimson ribbon are the former Long Service Medal of the H.E.I. Company’s European troops and the Meritorious and Long Service medals of the Indian Native Army.
3. Now replaced by military effigy of King Edward VII.
The Long Service and Good Conduct (Navy) Medal was instituted in 1831. Blue: Ribbon, white, with gold edges (Plate II).

The Volunteer Long Service Medal.—Instituted in 1894.Hooked on the reverse. Red, with white edges. Obverse: A scroll within a wreath, inscribed FOR LONG SERVICE IN THE VOLUNTEER FORCE. Replaced by the Territorial Long Service Medal (1908), of which the ribbon is green with a yellow centre; and the obverse a band of the king’s crown, faced and supported by two ribbons, with the Imperial Yeomanry Long Service Medal a yellow ribbon, the Honourable Artillery Company’s Medal a black, red and yellow ribbon. All these are shown on Plate II.1

The Medal for the Best Shot in the Army was instituted in 1896. Obverse: Bust of Queen Victoria (now effigy of King Edward VII). Reverse: A winged Victory crowning a warrior. Ribbon: Red, with two narrow black stripes on each edge, the two black stripes being divided by a narrow white one. There is also a Medal for the Indian Native Army, which has an orange ribbon.

The Medal for Naval Gunnery was instituted in 1903. Ribbon: Red centre, flanked by two narrow white stripes, two broad blue stripes at edges (Plate II).

Amongst medals of the last class may be mentioned the Jubilee Medals of 1887 and 1897, the Coronation Medal of 1902, the Royal Victorian Medal (this, however, is a sort of sixth class of the Royal Victorian Order, for which see Knighthood) and the medals awarded for Durbars.

United States.—The war medals and decorations of the United States, although few in number, are interesting, as they follow a peculiar system in the colours of the ribbons.

The principal military decorations of the United States is the "Medal of Honor," which is awarded for the most meritorious bravery or special good conduct during the Civil War. In its present form it is a five-pointed star, with a medallion in the centre bearing a head of Minerva and round it the words United States of America. On each ray of the star is an oak leaf, and the points themselves are trefoil shaped. A laurel wreath, in green enamel, encircles the whole, and this wreath is surmounted by VALOR, which in turn is surmounted by an eagle that attaches the decoration to the ribbon. The whole is attached by a blue ribbon.

The decoration is sometimes accompanied by a badge of blue silk with the thirteen stars in white.

The original form of the decoration, prior to the Civil War, consisted of a cross, the points of which were of laurel and oak, and the design in the central medallion was a figure of Minerva standing, with her left hand resting upon a conquer’s fasces and her right warding off with a shield the figure of Discord.

The background was formed by thirty-four stars. The decoration was surmounted by a trophy of crossed guns, swords, &c., with eagle above, and the ribbon was designed of the national colours, as follows: thirteen alternate red and white stripes, and across the ribbon at the top a broad band of blue (pale blue gues and apricot-wine red), the ornamentation being carried out by a clasp bearing two cornucopias and the arms of the U.S. The present decoration does not have this badge, but is suspended from a concealed bar brooch.

Another form of the decoration was the "Merit" Medal. This bears on the obverse an eagle, surrounded by the inscription VIRTUTIS ET AVDACIAE MONUMENTVM ET PRAEMIVM, and on the reverse the inscription FOR MERIT, surrounded by an oak-leaf wreath. On the upper part of the exergue is UNITED STATES ARM, and below fourteen stars. The ribbon is red, white and blue, in six stripes, two red stripes divided by a fine white line in the centre, two white on either side of the red and two blue forming the two outer edges.

When the obverse medals proper, issued generally to all those who took part in the events commemorated.

The Civil War Medal bears on the obverse the portrait of Lincoln, surrounded by an inscription taken from his famous Second Inaugural Address, and on the reverse the words FOR ALL. On the reverse is the inscription THE CIVIL WAR 1861-1865 surrounded by a wreath of oak leaves and olive branches. The ribbon is somewhat similar to that last described; the blue stripe, however, is in the centre, divided as before by a white line, and the design is carried out in gold.

The “Indian Wars” Medal is interesting from the fact that its reverse was copied on other medals, this making it, in a sense, a general service medal. On the obverse is a mounted Indian in full dress, and on the reverse, Indian Wars, in the lower a buffalo’s skull with arrow-heads on either side. What we have called the “general service” design on the reverse is composed of (a) an eagle perched on a cannon, supported by five standards (typifying the five great wars of the United States), rifles, Indian shield, spear and arrows, Filipino war carver’s baton, and a scroll inscribed with the words FOR SERVICE; (b) in exergue, above, UNITED STATES ARMY, below, thirteen stars.

The Ribbon of the Indian Medal, vermillion, with deep red edges.

The “War with Spain” Medal bears on the obverse a castle with two towers, and the words Peace With Spain, and on the reverse the words 1ST MAY 1898–1ST JUNE 1898.

The “Philippine Insurrection” Medal bears on the obverse a coco-nut palm tree, with, on the left of it, a lamp (typifying Enlightenment), and on the right a balance (representing Justice), surmounted by the words PHILIPPINE INSURRECTION August 1899. The ribbon is blue, with two red stripes near the edges.

The “China Relief” Medal bears on the obverse a Chinese dragon, surrounded by the inscription CHINA RELIEF EXPEDITION 1900, and at bottom the date 1900-1901. Reverse: As for “Indian Wars” medal. Ribbon: Lemon-yellow, with narrow blue edges.

It is interesting to note that in the case of two of these medals the national colours of the enemy (Spain and China) furnish those of the ribbon: on the reverse the Spanish flag were red, white and blue, and these also figure, in spite of their nationality, on the U.S. national colours, on the ribbons of the “Philippine” and “Congressional” Medals. The Indian ribbon is, similarly, of the colours of the buffalo, the colors used by the Indians, white, red, black, and yellow, being the nearest and the red nearest the centre.

The “China Relief” Medal is, similarly, of a gold or silver medal. It is awarded for bravery in saving life by land or sea.

Other Countries.—As has been mentioned above, foreign decorations for military service usually take the form of Orders in many classes. There are, however, numerous long service decorations, which need not be specified. The most famous of the European war and service decorations are the Prussian Iron Cross, the French Médaille Militaire, and the Russian St George’s Cross; all these are individual decorations.

The Iron Cross is given to officers and soldiers for distinguished service in war. It was founded, in the enthusiasm of the War of Liberation movement, on the 1st of March 1813, and revived at the outbreak of the "War for Unity" against France, 19th of July, 1870. The cross is a Maltese cross of cast iron edged with silver. The 1813-15 crosses have the initials F. W. (Friedrich Wilhelm) in the centre, a crown in the upper limb of the cross, and the date 1813 at the base. The 1870-71 crosses have on the reverse, in the centre, a crown on the upper and date on the lower limb of the cross. There are certain distinctions between the Grand Cross, which is worn at the neck, the 1st Class Cross which is worn as an Order suspended from a ribbon, and the 2nd Class Cross, which is worn on the breast.

In 1870 the Norwegian, Spanish, and Danish crosses were granted, and a cross superposed on a many-pointed star, having in its centre the date 1870-1871 within a wreath. The reverse has W. and a crown, with, for combatants the inscription Den siegreichen Heere, and for non-combatants with, the words der besiegten Kriege, with the date 1870-1871. There are certain distinctions between the Grand Cross, which is worn at the neck, the 1st Class Cross which is worn as an Order suspended from a ribbon, and the 2nd Class Cross, which is worn on the breast.

The cross was copied on the ribbons of the other three crosses, and the date 1870-1871 was inscribed on the ribbon. The Spanish and Danish crosses were inscribed with the words Gott war mit uns, the Danish with the words Gud var med os. The award of the Iron Cross to the rank and file carries with it an allowance of 3-6 marks monthly.

Medea (Gr. Μήδεα), in Greek legend, a famous sorceress, daughter of Aeetes, king of Colchis. Having been thrown into prison by her father, who was afraid of being injured by her witchcraft, she escaped by means of her art and fled to the temple of Helios the Sun-god, her reputed grandfather. She fell in love with Jason the Argonaut, who reached Colchis at this time, and exacted a terrible revenge for her faithlessness (see Argonauts and Jason). After the murder of Jason's...
second wife and her own children, she fled from Corinth in her car drawn by dragons, the gift of Helios, to Athens, where she married king Aegeus, by whom she had a son, Medus. But the discovery of an attempt on the life of Theseus, the son of Aegeus, forced her to leave Athens (Apollodorius i. 9, 28; Pausanias ii. 3, 6–11; Diod. Sic. iv. 45, 46, 54–56). Accompanied by her son, she returned to Colchis, and restored her father to the throne, of which he had been deprived by his own brother Perses. Medus was regarded as the eponymous hero and progenitor of the Medes. Medea was honoured as a goddess at Corinth, and was said to have become the wife of Achilles in the Elysian fields. The chief seat of her cult, however, was Thessaly, which was always regarded as the home of magic.

As time went on her character was less favourably described. In the case of Jason and the Argonauts, she plays the part of a kindly, good-natured fairy; Euripides, however, makes her a barbarous priestess of Hecate, while the Alexandrian writers depicted her in still darker colours. Some authorities regard Medea as a lunar divinity, but the ancient conception of her as a Thessalian sorceress is probably correct. The popularity of the story of Jason and Medea in antiquity is shown by the large amount of literature on the subject. The original story was probably contained in an old epic poem by Ἰάκωβος πατρός του, the authorship of which was ascribed to Prodicus of Phocaea. It is given at some length in the fourth Pythian ode of Pindar, and forms the subject of the Argonautica of Apollonius Rhodius. There is a touching epistle (Medea to Jason) in the Heroïdes of Ovid. Medea is the heroine of extant tragedies of Euripides and Seneca; those of Aeschylus and Euphorion (adapted from Euripides) are lost. Neophron of Sicyon and Melanthius wrote plays of the same name. Among modern writers on the same theme may be mentioned T. Cornelle, F. Grillparzer and M. Cherubini (opera).

The death of Glaucus and the murder of her children by Medea was frequently represented in ancient art. In the famous painting at Pompeii of Medea and her daughter, Medea is deliberating whether or not she shall kill her children; there are copies of this painting in the mural decorations of Herculanenum and Pompeii.

See Léon Mailloër, Médée: étude sur la littérature comparée, an account of Medea in Greek, Roman, middle age and modern literature (1898); and the articles in Daremberg and Saglio’s Dictionnaire des antiquités and Roscher’s Lexicon der Mythologie.

MEDELLÍN—MEDFORD

MEDFORD, a city, including several villages, of Middlesex county, Massachusetts, U.S.A., on the Mystic river and Lakes, 5 m. N. by W. of Boston. Pop. (1800), 18,244, of whom 4327 were foreign-born; (1910 census) 23,150. The city is served by the Southern Division and a branch of the Western Division of the Boston & Maine railroad, and is connected with Boston and neighbouring cities by electric railways. The Mystic River, a tidewater stream, is navigable for small craft as far as the centre of the city. There are manufactures of considerable importance, including bricks and tiles, woodmills, carriages and wagons, food products, iron and steel building materials and machinery. The city covers a land area of about 8 sq. m., along the Mystic river, and extending to the hills. The western portion borders the Upper and Lower Mystic Lakes, which are centres for boating. In the north-west portion of Medford is a part of the Middlesex Fells, a heavily wooded reserve belonging to the extensive Metropolitan Park System maintained by the state. The broad parkways of this system also skirt the Mystic Lakes, and here is the greater part (1907, 267 out of 291 acres) of the Mystic River Reservation of the Metropolitan System. Among the city parks are Hastings, Brooks, Logan, Tufts and Magoun. Within the city limits are some of the oldest and most interesting examples of American domestic architecture in America, including the so-called Cradock House, (actually the Peter Tufts house, built in 1677–1680), the “Wellington House,” built in 1659, and the “Royall House.” The last was built originally by Governor John Winthrop for the tenants of his Ten Hills Farm, and was subsequently enlarged and occupied by Lieut.-Governor John Usher, and by Isaac Royall* (c. 1720–1781) and his son, Isaac Royall, Jun.

Medford has a public library of about 35,000 volumes, housed in the colonial residence (reconstructed) of Thatcher Magoun. The city also has a city hall, a high school and manual training school, an opera house, and one of the handsomest armory buildings in the country (the home of the Lawrence Guard), presented by General Samuel C. Lawrence (b. 1832), a liberal benefactor of Medford institutions and the first mayor of the city (1822–1824). The Salem St. Burying Ground, dating from 1689, is one of the oldest burial places in America. The Medford Historical Society maintains a library and museum in the birthplace of Lydia Maria Child. Medford is the seat of Tufts College, planned and founded as a Universalist institution in 1852 by Hosea Ballou, its first president, and others, and named in honour of Charles Tufts (1781–1876), a successful manufacturer, who gave the land on which it stands. The college, which had 1120 students and 217 instructors in 1900, comprises a college of letters, a divinity school, and a school of engineering (all in Medford), and medical and dental schools in Boston; it is now undenominational. Among the twenty college buildings, the Barnum Museum of Natural History (1885) founded by Phineas T. Barnum, and the Eaton Memorial Library (1907), presented by Mrs Andrew Carnegie in memory of her pastor, are noteworthy. The college endowment amounted in 1908 to $2,300,000.

Medford was first settled in 1630. A considerable portion of its area formed the plantation of Matthew Cradock (d. 1641), first governor of the Massachusetts Bay Company, who in 1640

AMEDBLIK, a seaport of Holland, on the Zuider Zee, the terminus of a branch railway from Hoorn, 103 m. S. Pop. (1903), 3012. Once the capital of West Friesland and a prosperous town, many of its streets and quays are now deserted, though the docks and basins constructed at the end of the 16th and beginning of the 17th centuries could still afford excellent accommodation for many ships. Close to the harbour entrance stands the castle built by Florens V., Count of Holland, in 1285. It has been restored, and is used as a court of justice. The...
MEDHANKARA—MEDIA

sent out agents to settle his lands. John Winthrop’s “Ten Hills Farm,” partly within the present limits of Medford, was settled soon afterwards. One of the earliest industries was ship-building. John Winthrop’s “Blessing of the Bay,” built on the Mystic in 1631–1632, being one of the first keels laid on the continent. In 1802 Thatcher Magoun began building sea-going vessels, and many of the famous privateers of the War of 1812 were constructed here. By 1845 Medford employed fully a quarter of all the shipwrights of the state. The industry gradually lost its importance after the introduction of steamships, and the last keel was laid in 1873. Another early industry was the distilling of rum; this was carried on for two centuries, especially by the Hall family and, after about 1830, by the Lawrence family, but was discontinued in 1905. The manufacture of brick and tile was an important industry in the 17th century. The Cradock bridge, the first toll-bridge in New England, was built across the Mystic in 1638; over it for 150 years ran the principal thoroughfare, from Boston to Maine and New Hampshire. The course of Paul Revere’s ride lay through Medford Square and High Street, and within a half-hour of his passage the Medford minute men were on their way to Lexington and Concord, where they took part in the engagements with the British. After the Battle of Saratoga many of Burgoyne’s officers were quartered here for the winter. The Middlesex Canal was opened through Medford in 1803, and the Boston & Lowell railroad (now the southern division of the Boston & Maine) in 1831. Medford was chartered as a city in 1892.

See Charles Brooks, History of the Town of Medford (Boston, 1855; enlarged by J. M. Usher, Boston, 1886); Historical Register of the Medford Historical Society (1898 et seq.); Proceedings of the One Hundredth Anniversary of the Settlement of Medford (Medford, 1905); S. A. Drake, History of Middlesex County (2 vols., Boston, 1880) and Helen Tilden Wild, Medford in the Revolution (Medford, 1903).

MEDHANKARA, the name of several distinguished members, in medieval times, of the Buddhist order. The oldest flourished about A.D. 1200, and was the author of the Vinaya Artha Samuccaya, a work in the Sinhalese language on Buddhist canon law. Next to him came Ariánaka Medhankara, who presided over the Buddhist council held at Polonnaruwa, when the capital of Ceylon, in 1250. The third Vanaratana Medhankara, flourished in 1280, and wrote a poem in Pali, Jina Carita, on the life of the Buddha. He also wrote the Payoga Siddhi. The fourth was the celebrated scholar to whom King Parâkrama Bâhu IV. of Ceylon entrusted in 1307 the translation from Pali into Sinhalese of the Tipitaka, the holy scriptures of the Buddhist order in Sinhalese. The fifth, a Burmese, was called the Sangharâja Nava Medhankara, and wrote in Pali a work entitled the Loka Padîsa Sâra, on cosmogony and allied subjects.

See the Journal of the Pali Text Society, 1882, p. 126; 1886, pp. 62, 67, 72; 1890, p. 63; 1896, p. 43; Mahâvamsa, ch. xi., verse 85. (T. W. R. D.)

MEDHURST, WALTER HENRY (1796–1857), English Congregationalist missionary to China, was born in London and educated at St Paul’s school. He learned the business of a printer, and having become interested in Christian missions he sailed in 1816 for the London Missionary Society’s station at Malacca, which was intended to be a great printing-centre. He became proficient in Malay, in a knowledge of the written characters of Chinese, and in the colloquial use of more than one of its dialects. He was ordained at Malacca in 1819, and engaged in missionary labours, first at Penang, then at Batavia, and finally, when peace was concluded with China in 1842, at Shanghai. There he continued till 1856, laying the foundations of a successful mission. His principal labour for several years, as one of a committee of delegates, was in the revision of existing Chinese versions of the Bible. The result was a version (in High Wên-lij) marvellously correct and faithful to the original. With John Stonach he also translated the New Testament into the Mandarin dialect of Nanking. His Chinese-English and English-Chinese dictionaries (each in 2 vols.) are still valuable, and to him the British public owe its understanding of the teaching of Hung-Sew-Tseuen, the leader of the Tai-ping rising (1851–64).

The university of New York conferred upon him in 1843 the degree of D.D. Medhurst left Shanghai in 1856 in failing health, and died two years after reaching London, on the 24th of January 1857. His son, Sir Walter Henry Medhurst (1822–1885), was British consul at Hankow and afterwards at Shanghai.

MEDIA, the ancient name of the north-western part of Iran, the country of the Medes, corresponding to the modern provinces of Azerbaijan, Ardelen, Irak Ajemi, and parts of Kurdistan. It is separated from Armenia and the lowlands on the Tigris (Assyria) by the mighty ranges of the Zagros (mountains of Kurdishistan; in its northern parts probably called Choastras, Plin. v. 68), and in the north by the valley of the Araxes (Aras). In the east it extends towards the Caspian Sea; but the high chains of mountains which surround the Caspian Sea (the Parachoathras of the ancients and the Elburz, separate it from the coast, and the narrow plains on the border of the sea (Gilan, the country of the Gelaeus and Amardi, and Mazandaran, in ancient times inhabited by the Tapuri) cannot be reckoned as part of Media proper. The greater part of Media is a mountainous plateau, about 3000–5000 ft. above the sea; but it contains some fertile plains. The climate is temperate, and with cold winters in strong contrast to the damp and unwholesome air of the shores of the Caspian, where the mountains are covered with a rich vegetation. Media contains only one river, which reaches the sea, the Seni Rud (Amaruds), which flows into the Caspian; but a great many streams are exhausted after a short course, and in the north-west is a large lake, the lake of Urmia or Urmiâ.1 From the mountains in the west spring some great tributaries of the Tigris, viz. the Divalya (Gyndes) and the Kerkhek (Chouaspes). Towards the south-east Media passes into the great central desert of Iran, which eastwards of Rhagae (mod. Rai, near Teheran), in the region of the “Caspian gates,” reaches to the foot of the Elburz chain. On a tract of about 150 m. the western part of Iran is connected with the east (Khorasan, Parthyaea) only by a narrow district (Choaren and Comiene), where human dwellings and small villages can exist.

The people of the Mada, Medes (the Greek form Mēdōs is Ionian for Mābō) appear in history first in 836 b.c., when the Assyrian conqueror Shalmaneser II. in his wars against the tribes of the Zagros received the tribute of the Amadai (this form, with prosthetic ω-, which occurs only here, has many analogies in the names of Iranian tribes). His successors undertook many expeditions against the Medes (Mada). Sargon in 715 and 713 subjected them to the far mountain Bikni, i.e. to the Zagros, and the borders of the desert. They were divided into many districts and towns and petty local chieftains; from the names which the Assyrian inscriptions mention, we learn that they were an Iranian tribe and that they had already adopted the religion of Zoroaster. In spite of different attempts of some chieftains to shake off the Assyrian yoke (cf. the information obtained from prayers to the Sun-god for oracles against these rebels: Knudtzon, Assyrische Gebete an den Sonnengott), Media remained tributary to Assyria under Sargon’s successors, Sennacherib, Esar-haddon and Assur-bani-pal.

Herodotus, i. 101, gives a list of six Median tribes (γεῖα), among them the Parataceti, the inhabitants of the mountainous highland of Paratacevi, the district of Isahan, and the Magoi, i.e. the Magians, the hereditary caste of the priests, who in Media took the place of the “fire-kindlers” (athravan) of the Zoroastrian religion, and who spread from Media to Persia and to the west. But the Iranian Medes were not the only inhabitants of the country. The names in the Assyrian inscriptions prove that the tribes in the Zagros and the northern parts of Media were not Iranians nor Indo-Europeans, but an aboriginal population, like the early inhabitants of the range of the Caucasus.

1 Anc. Martiane, Strabo xi. 539; Martiane, Ptol. vi. 2, probably identical with the name Matiane, Matiene, by which Herodotus i. 189, 202, i. 34, 49, 52 (in i. 72 and vii. 72 they seem to be a different people in Asia Minor); Polyb. v. 44, 9; Strabo i. 49, ii. 73, xi. 509, 514, 533, 535; Plin vi. 48, designate the northern part of Media.

20
We can see how the Iranian element gradually became dominant; princes with Iranian names occasionally occur as rulers of these tribes. But the Gelae, Tapuri, Cadussi, Amardi, Utii and other tribes in northern Media and on the shores of the Caspian were not Iranians. With them Polibius v. 44, 9, Strabo xi. 597, 508, 514, and Pliny vi. 49, mention the Anarici, whom they consider as a particular tribe; but in reality their name, the "Not-Arians," is the comprehensive designation of all these small tribes.

In the second half of the 7th century the Medians gained their independence and were united by a dynasty, which, if we may trust Herodotus, derived its origin from Deioces (q.v.), a Median chieftain in the Zagros, who was, with his kinsmen, transported by Sargon to Hamath (Hamah) in Syria in 715 B.C. The kings, who created the Median Empire, were Phraortes and his son Cyaxares. Probably they were chieftains of a nomadic Median tribe in the desert, the Manda, mentioned by Sargon; for the Babylonian king Nabonidus designates the Medians and their kings always as Manda. The origin and history of the Median Empire is quite obscure, as we possess almost no contemporary information, and no single monument or inscription from Media itself. Our principal source is Herodotus, who wrongly makes Deioces the first king and uniter of the whole nation, and dates their independence from c. 710 B.C. But his account contains real historical elements, whereas the story which Ctesias gave (a list of nine kings, beginning with Artabaces, who is said to have destroyed Nineveh about 880 B.C., preserved in Diod. ii. 32 sqq. and copied by many later authors) has no historical value whatever, although some of his names may be derived from local traditions. According to Herodotus, the conquests of Cyaxares were interrupted by an invasion of the Scythians, who founded an empire in western Asia, which lasted twenty-eight years. From the Assyrian prayers to the Sun-god, mentioned above, we learn that the Median dynasty, which tried rebellions against the Assyrians in the time of Esar-haddon and Assur-bani-pal, were allied with chieftains of the Cimmerians (who had come from the northern shore of the Black Sea and invaded Armenia and Aria Minor), of the Sapardas, Ashguzas and other tribes; and from Jeremiah and Zephaniah we know that a great invasion of Syria and Palestine by northern barbarians really took place in 626 B.C. With these facts the traditions of Herodotus must, in some way be connected; but at present it is impossible to regain the history of these times. The only certain facts are that in 606 Cyaxares succeeded in destroying Nineveh and the other cities of Assyria (see PHRAORTES and DEIOCES).

From then the Median king ruled over the greatest part of Iran, Assyria and northern Mesopotamia, Armenia and Cappadocia. His power was very dangerous to their neighbours, and the exiled Jews expected the destruction of Babylon by the Medes (Isa. xili., xiv., xxii.; Jerem. i. li.). When Cyaxares attacked Lydia, the kings of Cilicia and Babylon intervened and negotiated a peace in 585, by which the Hlyas was established as the common boundary. Nebuchadrezzar married a daughter of Cyaxares, and an equilibrium of the great powers was maintained till the rise of Cyrus.

About the internal organization of the Median Empire we know only that the Greeks derive a great part of the ceremonial of the Persian court, the costume of the king, &c., from Median. But it is certain that the national union of the Median clans was the work of their kings; and probably the capital Ecbatana (q.v.) was created by them.

By the rebellion of Cyrus, king of Persia, against his suzerain Astyages, the son of Cyaxares, in 553, and his victory in 550, the Medes were subjected to the Persians. In the new empire they retained a prominent position; in honour and war they stood next to the Persians; the ceremonial of their court was adopted by the new sovereigns who in the summer months resided in Ecbatana, and many noble Medes were employed as officials, satraps and generals. After the assassination of the usurper Smerdis, a Mede Fravartish (Phraortes), who pretended to be of the race of Cyaxares, tried to restore the Median kingdom, but was defeated by the Persian generals and executed in Ecbatana (Darius in the Behistun inscr.). Another rebellion, in 469, against Darius II. (Xenophon, Hellen. i. 2, 10) was of short duration. But the non-Aryan tribes of the north, especially the Cusarions, were always troublesome; many abortive expeditions of the later kings against them are mentioned.

Under the Persian rule the country was divided into two satrapies. The south, with Ecbatana and Rhagae (Rai), Media proper, or "Great Media," as it is often called, formed in Darius' organization the eleventh satrapy (Herodotus 92), together with the Paracarnians and Orthocorybantiens; the north, the district of Matiane (see above), together with the mountainous districts of the Zagros and Assyria proper (east of the Tigris) was united with the Alarodians and Saspirians in eastern Armenia, and formed the eighteenth satrapy (Herod. iii. 94; cf. v. 49, 52, vii. 72). When the empire decayed and the Carduchi and other mountainous tribes made themselves independent, eastern Armenia became a special satrapy, while Assyria seems to have been united with Media; therefore Xenophon in the Anabasis ii. 4, 27; iii. 5, 15; vii. 8, 25; cf. iii. 4, 8 sqq. always designates Assyria by the name of Media.

Alexander occupied Media in the summer of 330; in 328 he appointed Atropates, a former general of Darius (Arrian iii. 8, 4), as satrap (vii. 18, 5, vi. 29, 9), whose daughter was married to Perdiccas in 324 (Arrian vi. 4, 5). In the partition of his empire, southern Media was Media given to the Macedonian Peithon; but the north, which lay far off and was of little importance for the generals who fought for the inheritance of Alexander, was left to Atropates. While southern Media with Ecbatana passed to the rule of Antigonus, and afterwards (about 310) to Seleucus I.; Atropates maintained himself in his satrapy and succeeded in founding an independent kingdom. Thus the partition of the country, which the Persian had introduced, became lasting; the north was named Atropatene (in Plin. vi. 42, Atrapatene; in Ptol. vi. 2, 5, Tropatene; in Polyb. vi. 44 and 55 corrupted in τα σαμαρτια και λαοίμενα), after the founder of the dynasty, a name which is preserved in the modern Azerbaijan; cf. Nöldke, "Atropatene," in Zeitsschrift der deutschen morgenl. Gesellschaft, 34, 692 sqq. and Marquart, Ernährung, p. 158 sqq. The capital was Gazaca in the central mountains, and the strong castle Phraaspia (Dio Cass. xiii. 26; Plut. Antep. 38; Ptol. vi. 2, 10) or Vera (Strabo xi. 523), probably identical with the Greek ruin Taktii Suleiman, with remains of Sassanid fire-altar and of a later palace. The kings had a strong and warlike army, especially cavalry (Polyb. v. 55; Strabo xi. 523). Nevertheless, King Ardasheres was forced by Antiochus the Great in 220 to conclude an advantageous treaty (Polyb. v. 55), and in later times the rulers became in turn dependent on the Parthians, on Tigranes of Armenia, and in the time of Pompey who defeated their king Darius (Appian, Mithr. 108), on Antonius (who invaded Atropatene) and on Augustus of Rome. In the time of Strabo (A.D. 17), the dynasty existed still (p. 523); in later times the country seems to have become a Parthian province.

Atropatene is that country of western Asia which was least of all influenced by Hellenism; there exists not even a single coin of its rulers. But the opinion of modern authors—that it had been a special refuge of Zoroastrianism—is based upon a wrong etymology of the name (which is falsely explained as "country of the plume-worship"), and has no foundation whatever. There can be no doubt that the kings adhered to the Persian religion; but it is not probable that it was deeply rooted among their subjects, especially among the non-Aryan tribes.

Southern Media remained a province of the Seleucid Empire for a century and a half, and Hellenism was introduced everywhere. "Media is surrounded everywhere by Greek towns, in pursuance of the plan of Alexander, which protect it against the neighbouring barbarians," says Polibius (x. 27). Only Ecbatana retained its old character. But Rhagae became a Greek town, Europus; and with it Strabo (xi. 524) names Laodicea, Apamea, Heraclea or Achais (cf. Plin. vi. 48). Most of them were founded
by Seleucus I. and his son Antiochus I. In 221, the satrap Molon tried to make himself independent (there exist bronze coins with his name and the royal title), together with his brother Alexander, satrap of Persia, but they were defeated and killed by Antiochus the Great. In the same way, in 161, the Median satrap Timarchus took the diadem and conquered Babylonia; on his coins he calls himself “the great king Timarchus”; but this time again the legitimate king, Demetrius I., succeeded in subduing the rebellion, and Timarchus was slain. But with Demetrius I. the dissolution of the Seleucid Empire begins, which was brought on chiefly by the intrigues of the Romans, and shortly afterwards, about 150, the Parthian king, Mithradates I. (q.v.), conquered Media (Justin xii. 6). From this time Media remained subject to the Arsacids, who changed the name of Rhagae, or Europus, into Arsacia (Strabo xi. 524), and divided the country into five small provinces (Isidorus Charac.). From the Arsacids or Parthians, it passed in A.D. 226 to the Sassanids, together with Atropatene. By this time the old tribes of Aryan Iran had lost their character and had been amalgamated into the one nation of the Iranians. The revival of Zoroastrianism, which was enforced everywhere by the Sassanids, completed this development. It was only then that Atropatene became a principal seat of fire-worship, with many fire-altars. Rhagae now became the most sacred city of the empire and the seat of the head of the Zoroastrian hierarchy; the Sassanid Aresta and the tradition of the Parsees therefore consider Rhagae as the home of the family of the Prophet. Henceforth the name of Media is used only as a geographical term and begins to disappear from the living language; in Persian traditions it occurs under the modern form Māh (Armen. Mai; in Syriac the old name Madai is preserved; cf. Marquart, Ernoshahr, tch seq.).

For Mahommedan history see CALIPHATE; for later history SELJUKS and PERSIA.

(Ed. M.)

**MEDIATION** (Lat. medio, middle), in the international sense, the intervention of a third power, on the invitation or with the consent of two other powers, for the purpose of arranging differences between the latter without recourse to war. Mediation may also take place after war has broken out, with a view to putting an end to it on terms. In either case the mediating power negotiates on behalf of the parties who invoke or accept its aid, but does not go farther. Unlike an arbitrating power the mediator limits his intervention to suggestion and advice. His action is liable to be arrested at any time at the will of either party unless otherwise agreed, in which case to arrest it prematurely would be a breach of good faith. The difference between mediation and arbitration may be stated to consist in the words of the Digest (lib. iv. tit. 8, § 13): “Recepisse autem arbitrum videtur, ut ait Pedius, qui judicis partes susceptit finemque se sua sententia controversiis impositorum pollicetur. Quod si hactenus intervenit ut experiret un concilio suo vel auctoritate discuti litem paternetur, non videtur arbitrum recepisse.”

Some writers distinguish mediation from “good offices,” but the distinction is of little practical value. We may, if we please, regard “good offices” as incitative mediation, and “mediation” as good offices brought to the birth. Thus we may say that a third power renders “good offices” when it brings the parties together so as to make diplomatic negotiations between them possible; whilst if it takes an active part in those negotiations it becomes for the time being a mediator. The spontaneous yet successful effort made by France and Belgium in 1890 to bring together the Russian and Japanese governments, and, to secure their appointing delegates to discuss terms of peace, although not strictly mediation, was closely akin to it.

Of successful mediation in the strict sense there have been many instances: that of Great Britain, in 1825, between Portugal and Brazil; of France, in 1839-1850, when differences arose between Great Britain and Greece; of the Great Powers, in 1868-1869, when the relations of Greece and Turkey were strained to breaking-point by reason of the insurrection in Crete; of Pope Leo XIII., in 1885, between Germany and Spain in the matter of the Caroline Islands. In these cases mediation averted war. The Austro-Prussian War of 1866, the war between Chile and Peru in 1882, and that between Greece and Turkey in 1897, are instances of wars brought to a close through the mediation of neutral powers. Mediation has also been occasionally employed where differences have arisen as to the interpretation of treaties or as to the mode in which they ought to be carried out: as when Great Britain mediated between France and the United States with regard to the Treaty of Paris of the 4th of July 1830. In one case at least mediation has been successful after a proposal for arbitration had failed. In 1844, when war between Spain and Morocco was threatened by reason of the frequent raids by the inhabitants of the Rif on the Spanish settlement of Ceuta, Spain declined arbitration on the ground that her rights were too clear for argument. But both she and Morocco subsequently accepted joint mediation at the hands of Great Britain and France.

The cause of mediation was considerably advanced by the Declaration of Paris of 1856. The plenipotentiaries of Great Britain, France, Austria, Russia, Sardinia and Turkey recorded in a protocol, at the instance of Lord Clarendon, their joint wish that “states between which any misunderstanding might arise should, before appealing to arms, have recourse so far as circumstances might allow (en tant que les circonstances l’admettraient) to the good offices of a friendly power.” Article 8 of the Treaty of Paris, concluded in the same year, stipulated that “if there should arise between the Sublime Porte and one or more of the other signing powers any misunderstanding which might endanger the maintenance of their relations, the Porte and each of such powers, before having recourse to the use of force, shall afford the other contracting parties the opportunity of preventing such as extremity by means of mediation.” These precedents (in which it will be seen that “good offices” and “mediation” are used interchangeably) were followed in the general act agreed to at the Conference held at Berlin in 1844-1845 the object of which was to secure religious and commercial liberty and to limit warlike operations in the Congo basin.

A special form of mediation was proposed by a delegate from the United States at the Peace Conference held at the Hague in 1899, and was approved by the representatives of the powers there assembled. The clause in which this proposal was embodied provided in effect that, whenever there is danger of a rupture between two powers, each of them shall choose a third power to which these differences shall be referred, and that, pending such reference, for a period not exceeding thirty days (unless the time is extended by agreement) the powers at issue shall cease to negotiate with each other and leave the dispute entirely in the hands of the mediating powers. The powers thus appealed to occupy a position analogous to that of seconds in a duel, who are authorized to arrange an “affair of honour” between their principals. This novel device has the advantage of toning down, if not of eliminating, personal and national prejudices by which controversy is frequently embittered. It also gets over the difficulty, often met with in arbitration, of choosing a referee satisfactory to both parties. The closer the relations between states become, the more their commercial interests are intertwined, the larger the part which mediation seems destined to play. It is true that states which have accepted the intervention of a mediator remain free to adopt or reject any advice he may give, but the advice of a disinterested power must always add considerable moral weight to the mediator’s arguments.

**MEDIATIZATION** (Ger. Medialisierung, from Lat. medius, middle), the process by which at the beginning of the 19th century, a number of German princes, hitherto sovereigns holding immediately of the emperor, were deprived of their sovereignty and mediatized by being placed under that of other sovereigns. This was first done on a large scale in 1803, when by a recess of the imperial diet many of the smaller fiefs were mediatized, in order to compensate those German princes who had been forced to cede their territories on the left bank of the
Rhine to France. In 1806 the formation of the Confederation of the Rhine involved an extension of this mediatizing process, though the abolition of the empire itself deprived the word “mediatizing” of its essential meaning. After the downfall of Napoleon the powers were besieged with petitions from the mediatized princes for the restoration of their “liberties”; but the congress of Vienna (1815) further extended the process of mediatization by deciding that certain houses hitherto immediate (i.e. Salm, Isenburg, Leyen) should only be represented mediately in the diet of the new Confederation. On the other hand, at Aix-la-Chapelle (1818) the powers, in response to the representations of the aggrieved parties, admonished the German sovereigns to respect the rights of the mediatized princes subject to them. Of these rights, which included the hereditary right to a seat in the estates, the most valued is that of Ehenbürtigkeit (equality of birth), which, for purposes of matrimonial alliance, ranks the mediatized princes with the royal houses of Europe. See August Wilhelm Heffer, Die Sonderrechte der Souveränen und der Mediatirten, vormals reichsstädtischen Häusern Deutschlands (Berlin, 1871). The mediatized families are included in the Almanach de Gotha.

MEDICAL EDUCATION. Up to 1858 each University, Great Hall in Great Britain and Ireland laid down its own regulations for study and examination, and granted its degree or licence without any State supervision. In that year, pursuant to the Medical Act, 21 & 22 Vict. c. 90, the General Medical Council of Medical Education and Registration was established, consisting of twenty-three members, of whom seventeen were appointed by the various licensing bodies and six by the Crown. This number was increased by the amended act of 1886 to twenty-nine, three of the six additional members being elected by the profession as “direct representatives. The object of the act was “to enable persons requiring medical aid to distinguish qualified from unqualified practitioners.” To this end the “Medical Register” was established, on which no person’s name could be inscribed who did not hold a diploma or licence from one or more of the licensing bodies after examination. By the 1886 act a qualifying examination was defined as “an examination in medicine, surgery, and midwifery,” conducted by universities or by medical corporations, of which one must be capable of granting a diploma in medicine, and one in surgery. The Council is authorized to require from the licensing bodies information as to courses of study and examinations, and generally as to the requisites for obtaining qualifications; and to visit and inspect examinations either personally or by deputy. If the visitors think the course of study and examination of any licensing body is not sufficient to ensure that candidates obtaining their qualification possess the requisite knowledge and skill for the efficient practice of their profession the Council, on a report being made, may represent the same to the Privy Council. The Privy Council may, if it sees fit, deprive the accused body of its power to grant registrable qualifications. From this statement it will be seen that the powers of the Council are limited; nevertheless, by their cautious application, and by the loyal manner in which the licensing bodies have acted on the recommendations and suggestions which have from time to time been made, the condition of medical education has been improved; and although there is not a uniform standard of examination throughout the United Kingdom, the Council has ensured that the minimum requirements of any licensing body shall be sufficient for the production of trustworthy practitioners.

One of the first subjects to which the Council applied itself was the establishment of a system of examinations in general knowledge. Such examinations have to be passed before beginning medical study. On presentation of a certificate to the registrars of the Council, and on evidence being produced that the candidate is sixteen years of age, his name is inscribed on the “Students’ Register.” The subjects of examinations are: (a) English language, including grammar and composition (marks not exceeding 5% of the total obtainable in this section may be assigned to candidates who show a competent knowledge of a short novel; (b) mathematics, comprising arithmetic, algebra, as far as simple equations inclusive; geometry, the subject-matter of Euclid, Books I., II., and III., with easy deductions; (c) one of the following optional subjects—Greek, French, German, Italian or any other modern language. Certificates are accepted from all the universities of Great Britain and Ireland, from the leading Indian and colonial universities, from government examination boards, and from certain chartered bodies. The German Abiturienten Examen of the gymnasia and real-gymnasia, the French diplomas of Bachelier ès Lettres and Bachelier ès Sciences, and corresponding entrance examinations to other continental universities are also accepted.

As regards professional education, the Council divided its resolutions into ‘requirements’ and ‘recommendations’; the former consisting of demands on the licensing bodies, non-compliance with which renders them liable to be reported to the Privy Council; the latter are regarded merely as suggestions for the general conduct of education and examination. The requirements may be summed up as follows: (a) Five years of bona-fide study between the date of registration and the date of the final examination for any diploma entitling the holder to be registered under the Medical Acts. (c) In every course of study and examination the student should be taught, as far as possible, the elements of solid and fluids, and the rudiments of heat, light and electricity; (ii) chemistry, including the principles of the science, and the details which bear on the study of medicine; (iii) elementary biology; (iv) anatomy; (v) physiology; (vi) materia medica; (vii) pathology; (viii) therapeutics; (ix) medicine, including medical anatomy and clinical medicine; (x) surgery, including surgical anatomy and clinical surgery; (xi) midwifery, including diseases of women and the practice of vaccination; (xii) forensic medicine; (xiii) hygiene; (xiv) mental disease. (d) The first of the four years must be passed at a school or schools of medicine recognized by any of the licensing bodies. (e) A student who has completed the first year may be passed at a university or teaching institution where the subjects of physics, chemistry and biology are taught; and that graduates in arts or science of any university recognized by the Council, who shall have spent a year or more of their time in study and examination, shall be held to have completed the first year of medical study. (e) The study of midwifery practice must consist of three months’ attendance on the indoor practice of a lying-in hospital, or the study and examination of the care of such persons, and that of not less than twelve months, five of which shall have been conducted throughout under the direct supervision of a registered practitioner.

The fifth year of study is intended to be devoted to clinical work and may be passed at any one or more of hospitals or dispensaries, British or foreign, recognized by the licensing authorities; six months of this year may be passed as a pupil to a practising possession such opportunities of imparting practical knowledge as shall be satisfactory to the medical authorities. This latter method is not allowed to employ more than one half the time required.

The recommendations of the Council contain suggestions which may or may not be acted on by the bodies. For the most part they are compiled with in connexion with the system of practical and clinical teaching.

The Council satisfies itself that its requirements are acted on, and that the examinations are “sufficient,” by cycles of inspection about every five years. The examination of each licensing body is visited by a medical inspector, who reports annually to the Privy Council of each report to the body for its information and remarks. As yet it has never been the duty of the Council to report to the Privy Council that any examination has not been found sufficient.—Universities in which attendance at lecture courses is not compulsory; and in all colleges and halls; for instance, botany and natural history are taught to their students, who are also examined in them. But with these exceptions the system of professional education is fairly uniform. The Council has long been engaged in the formation of a register of medical practitioners for all parts of the United Kingdom; this register is to be kept up to date by every medical practitioner and is to be made the basis of a medical directory to be published yearly by the Council.
tutor, an insight into methods of examination of diseases, and learns practically the use of the stethoscope and other aids to diagnosis, and of surgical and obstetrical instruments. In fact, it may be said that each subject of instruction is duplicated. If this is taken into account, it must be evident that the time of the student is fully occupied, and the belief is rapidly growing that five years is too short a period of study. As a matter of fact, the average time taken to obtain a B.A. degree is upwards of six years. The probability is that the solution of the difficulty will be found in the inclusion of such subjects as physics, biology and chemistry in a "preliminary scientific" examination, which may have been undertaken before registration as a medical student, thus leaving the whole five years to be devoted to purely professional study.

The German regulations in regard to professional study are few. They are those for the Staats Examens, for which the university degree is no longer necessary. The regulations for the admission of candidates to the Staats Examens are contained in the royal proclamations of the 22nd of June 1883. They comprise: (a) Certificate of a course of study at a classical gymnasium of the German Empire. In exceptional cases, the same from a classical gymnasium outside the German empire may be considered sufficient. (b) Certificate from a university, certifying a course of medical study of at least nine half-years at a university of the German empire. (c) Certificate that the candidate has passed, entirely at a German university, the medical Vorprüfung, and thereafter has attended for at least four half-years the medical studies of a university. (d) The special testimony of the clinical directors bearing witness that the candidate has taken part as Praktikant (clerk or dresser) during two half-years at the medical, surgical, and gynaecological clinics; has himself delivered two cases of labour in the presence of his teachers or assistant physicians; and has attended for a half-year as Praktikant the clinic for diseases of the eye.

The medical Vorprüfung referred to is necessary alike for the Staats Examens and the degree of Doctor of Medicine. It takes place at the beginning of the second year (fourth semester), and includes the subjects of experimental physics, chemistry, botany, zoology, anatomy and physiology. It is conducted by a board appointed yearly by the Minister of Education.

No one can practise medicine in France who does not possess the diploma of Doctor of Medicine of a French university. The qualification of Officier de santé is no longer granted.

Before he can inscribe as a student of medicine the applicant must have obtained the diplomas of Bachelier ès lettres and Bachelier ès sciences. Although the course of professional study may be completed in four years, a longer time is generally taken before the student proceeds to the final examination for the doctor's degree. The student is required to attend one-half of the lectures at each trimestre. If the student is a Bachelier ès lettres in the first year, he must attend for one-half of the classes. The second year is devoted to the study of medical science, and thus loses three months. The lectures are, however, closely attended. In contrast to the freedom in regard to attendance on systematic lectures, there are strict direction and control in regard to hospital attendance and practical courses. The student is required to sign a register ad hoc each time he goes in and out. From the beginning of the third year, e.g. from the ninth quarterly inscription, hospital attendance is enforced till the end of the fourth year. No one can renew his trimestral inscription without producing a schedule of his last trimestral stage, showing that during it he had not belonged himself more than five times without explanation. Practical work is obligatory during each of the four years.

Besides systematic courses of lectures, Conférences are held by the assistant-professors (agrégés) in natural history, physiology, general pathology, internal pathology, external pathology. At the end of the first year the student is examined in osteology, mythology and the practice of surgery. At the end of the second year he is examined in anatomy and physiology in all their branches; at the end of the third year, in medicine and surgery; at the end of the fourth year, an examination is held over the whole field of study.

No one is allowed to enter on the study of medicine without passing the Aréum examen of a secondary school. This is the equivalent of the German Abiturienten Examens of classical gymnasia. All such examinations must be passed in psychology, logic and history. The special professional examinations consist of: (1) preliminary scientific, in botany, zoology, physics, chemistry; (2) first special or professional, anatomy (orally and by dissections), physiology, and pharmacology; (3) second special or professional, written examinations in medicine, surgery, medical jurisprudence; practical and oral in operative surgery, in clinical medicine, and surgical; and oral in pathological anatomy, medicine, surgery; and midwifery. The completion of the full medical course takes six years, of which the first two are devoted to the study of the natural sciences.

Authorities.—The history of the development of medical education from the earliest times down to 1894 is found treated of generally by P. H. C. Meyer in Geschichte der medizinischen Wissenschaft (Leipzig, 1889-1905). The following works supply much material, including the gradual rise and development of teaching and examination: A History of the Medical Colleges in the United States (1886); The History of the Royal College of Surgeons of Ireland (1886); Early Days of the Royal College of Physicians of Edinburgh, by Sir H. Ritchie (1899); The Historical Sketch of the Royal College of Surgeons of Edinburgh, by Gairdner (1860); Memorials of the Faculty of Physicians and Surgeons of Glasgow, by Duncan (1896); The Story of the University of Edinburgh, by Sir A. Grant (1884); University of Glasgow, by Stewart (1891).

As late as 1880 medical education in the United States was in a deplorable condition. In the early history of the country, before and shortly after the beginning of the 19th century, the few medical colleges had shown a disposition to require a liberal education on the part of those who entered upon their courses, and some effort was made, through the agency of the state governments, to control the licence to practise. But as the country increased in population and wealth, and preliminary requirements were practically abolished, the length of the courses given each year was shortened to four or five months or less, and in the second and final year there was simply a repetition of the courses given during the first year. This is to be attributed mainly to the fact that there was no general national or state supervision of medical training. Medical colleges could obtain incorporation under state laws without difficulty, and brought considerabl e advantages in the way of prestige and increased practice to those concerned. That the existence of a college depended solely upon the fees of the students encouraged the tendency to make both entrance and graduation requirements as easy as possible, especially as there was no state supervision, and the mere possession of a diploma entitled the holder to practice. Fortunately, during the period of the practical character of the education in the better colleges fitted the graduates in some measure for the actual necessities of practice, while the good traditions of medicine as a learned profession stimulated those who adopted it as a career, so that in the main the body of practitioners respected and held the confidence and respect of the community. From the middle of the 19th century there has been constant agitation on the part of the physicians themselves for an improvement in medical education. The first notable result was an increase in the time of instruction from two to three years (Chicago Medical College, 1859; Harvard Medical School, 1871), the lengthening of each session to six
months or more, and the introduction of graded courses instead of a repetition of the same lectures every year. The improvement thus begun became marked during the decade 1890–1900, amounting almost to a revolution in the rapidity with which the course of instruction was amplified. Many factors co-operated to produce this result: the general development of scientific instruction in the colleges and secondary schools, the influence of the large number of medical graduates who completed their training by study in European schools, the adoption by many states of stringent regulations regarding the licence to practise within their borders, the good examples set by many leading schools in voluntarily raising their requirements for entrance and graduation, and, perhaps above all in its general effect, the agitation continually maintained by several national or state associations which in a measure have exerted the general regulating control that in other countries has been enforced by national legislation. Among the most influential of these associations are the American Medical Association, the American Academy of Medicine, the Association of American Medical Colleges, the Illinois State Board of Health, and the University of the State of New York.

The different states make their own general regulations as to the practice of medicine within their borders. Certain states recognize the medical diplomas granted by other states having equivalent standards of examination. Some states are required to be (a) graduation from a "reputable medical school," (b) certificates of moral character, (c) the applicant must be at least twenty-one years of age. These are usually left to the state boards, each one determining the matter for its own state, consequently a school may confer a degree recognized as reputable in several states but not in others. Only three or four states regulate the chartering of institutions of education. In the case of most colleges, articles of incorporation of a college or school by paying the necessary state fee, without question as to the ability of the incorporator to furnish an education. So strong, however, has been the growth of American public opinion that a four-years' course of medical training has become the standard in medical schools, and in the majority this is in addition to one or two years' training in the natural sciences. There are some sixty-five state boards, and many have adopted strong medical practice acts.

The standard of preliminary requirements for entrance to the medical schools is being gradually raised, and a large number of the states demand a certificate of a high school education, while the colleges recommend to be taken at a college of arts, which numbers more than half the American medical schools, accept as an entrance standard a certificate of at least one year's study at a high school. In the report for 1908 of the United States bureau of education of the National Education Association, which report the number of their students having an arts degree, it is stated that a degree was held by only 15% of the candidates in medicine. These students were mostly distributed between the Johns Hopkins Medical School (which from the beginning took only students in the upper third of the college class), the University of California, and the medical departments of the Universities of California, Michigan and Chicago (Rush Medical College) require entrance to the entrance of a two-years' college course, which must include French and German, together with physics, chemistry and biology. This tendency is in accordance with the educational plans recommended by the Council of Medical Education and adopted by the House of Delegates of the American Medical Association, of which the following is a summary:

1. Preliminary of a four-years' high school education or an examination such as would admit to a recognized university.

2. Previous to entering a medical college every student should receive from the state board a "medical student's entrance certificate" to be given on the production of credentials of training as above.

3. Four years of study in a medical college having a minimum of a 30-weeks' course each year, with not less than 30 hours' work per week.

4. Graduation from college to entitle a candidate to present himself for examination before the state board.

5. A satisfactory examination to be passed before the state board.

Practically all medical schools admit women, but there are three schools established especially for women, the Women's Medical College of Philadelphia, Pennsylvania; Women's Medical College, Baltimore, Maryland; New York Medical College and Hospital for Women—the last being one of the eighteen homoeopathic colleges of the United States.

W. H. H.; H. L. H.

MEDICAL JURISPRUDENCE, or FORENSIC MEDICINE, that branch of state medicine which treats of the application of medical knowledge to certain questions of civil and criminal law. The term "medical jurisprudence," though sanctioned by long usage, is really considered obsolete, since the subject is strictly a branch of medicine rather than of jurisprudence; it does not properly include sanitation or hygiene, both this and medical jurisprudence proper being distinct branches of state medicine.

The connexion between medicine and the law was perceived long before medical jurisprudence was recognized, or had obtained a distinct appellation. It first took its rise in Germany, and more tardily received recognition in Great Britain. Forensic medicine, or medical jurisprudence proper as distinguished from hygiene, embraces all questions which bring the medical man into contact with the law, and embraces (1) questions affecting the civil rights of individuals, and (2) injuries to the person.

I. — QUESTIONS AFFECTING THE CIVIL OR SOCIAL RIGHTS OF INDIVIDUALS

1. Development of the Human Frame.—The development of the physical and mental powers of the human being is a factor of great consequence in determining criminal responsibility, the capacity to contract contracts of all kinds, to enter into civil contracts, and in determining the personal identity of a living person or of a corpse. Human life is usually divided into the five periods of infancy, childhood, youth, manhood and old age. Some writers increase the number of these unnecessarily to seven periods.

Infancy is the period from birth till the first or milk set of teeth begin to be shed—usually about the seventh year. During this period the body increases in size and stature more, relatively, than in any other period of existence; and the mental faculties undergo great development. The milk teeth, twenty in number, are evolved in a definite order, beginning with the central incisors at about six months, and ending with the second molars about the termination of the second year. From the size and stature of the body, the development of the teeth, and the more or less advanced state of ossification or solidification of the bony skeleton, conclusions may be drawn as to the probable age of the infant.

Childhood extends from the commencement of the shedding of the milk teeth to the age of puberty—usually from the seventh to the fourteenth or fifteenth year. During this period the body expands, as well as the bony structures, without any clearly marked difference in structure being observable, except in the growth of the teeth, which is impossible to distinguish absolutely between the male and the female skeleton during this period. The milk teeth are shed, and are replaced by the second or permanent set, thirty-two in number, though these do not usually begin to develop.
Youth is marked at its commencement by the changes which occur at puberty—the development of the genitalia in both sexes, the appearance of pubic hair, and the general appearance of a beard in the male. The development of the breasts in the female, the appearance of the monthly flow in the female, and the ability to secrete semen in the male. Marked mental changes now occur, and the generative functions are perfected. Youth terminates at the end of the legal majority, twenty-one years, or perhaps the period ought to be extended to twenty-five years of age, as it is with some nations.

Maturity (or Womanhood) is the period of perfection of all the bodily and mental faculties. It ceases in woman with the cessation of the physiological monthly flow at about forty-five years of age; but in man it often extends to a much later period of life.

Old Age begins with the decay of the bodily and mental faculties, and is characterized by wrinkling of the skin, loss of the functions of the hair, and thinness of the body. In its later stages decay of the mental faculties, deafness, or loss of vision, and bowing of the spine are added.

2. **Duration of Human Life.**—The changes of human life form an important subject of inquiry, and on deductions from comparisons of birth and death rates is founded the system of annuities, insurance against loss in sickness, and the insurance of lives. Since the establishment of compulsory registration of deaths, our knowledge of the ordinary and extraordinary chances of human life has been extended, and surer data are available for calculations of probabilities of life, of survivourships, and of the payments which ought to be made in benefit clubs (see Insurance).

3. **Personal Identity.**—Where the identity has to be established or disproved after long absence, exposure to foreign climates and hardships, wounds, &c., the problem has often been extremely difficult. The data for identifying a person are those of personal and family likeness, stature, the colour of the eyes, peculiarities of garb and manner, recollection of antecedent events, but more especially marks on the person, either congenital or acquired. Such are scars, mottler’s marks, scars, or disfigured or badly united fractures, known to have existed upon the missing person (see Identification). In the case of the living, identification is more often a matter for the police officer than for the medical man. Bertillon and Galton have devised methods for the identification of criminals (see Anthropometry, and Finger-prints).

4. **Marriage.**—Under this head the medical jurist has to deal principally with the nubile age, viewed in the light of nature and according to legislative enactments, and with such physical circumstances as affect the legality of marriages, or justify divorce.

In Great Britain the age at which the sexes are first capable of propagating the species is later than in more southern climates. Ordinarily it does not occur before fifteen years of age for the male and fourteen for the female; exceptionally it occurs at the age of thirteen and of twelve (or even less) respectively in the male and female. By law, nevertheless, parents and guardians may, in England at all events, forbid the marriage of young people till the age of legal majority. The only physical signs which form a bar to marriage are physical inability to consummate, and the insanity of one of the parties at the time of marriage. Both these circumstances have been pleaded and sustained in the law courts. In other countries minor physical circumstances, as disease, are held to be legitimate.

5. **Impotence and Sterility.**—These are of importance in connection with legitimacy, divorce and criminal assaults. Impotency and sterility may arise from organic or from functional causes, and may be curable or incurable. Impotency (q.v.) is taken cognisance of by the law courts as a ground of divorce, and might, of course, be urged as a defence in a case of rape. Sterility is not a ground of divorce, but might be a question of importance in cases of legitimacy.

6. **Pregnancy.**—This subject presents one of the widest fields for medico-legal evidence. The limits of age between which it is possible, the limits of uestro-gestation, and the signs of pregnancy may all in turn be the subjects of investigation.

The limits of age between which pregnancy is possible are usually fixed by the appearance and cessation of the monthly flow; and these ordinarily begin about fourteen and cease at forty-five years of age. Occasionally they appear as early as the tenth year, and may continue till the end of the fifth decade of life. Cases, however, have occurred where a woman has conceived before menstruating; and a few doubtful cases of conception are recorded in women upwards of fifty or even sixty years of age. The general fact of pregnancy being limited by the age of puberty on the one hand and the cessation of menstruation on the other, by about between thirty and eighty-three years from the cessation of the last monthly flow, is well known, however, that among the higher animals the period of pregnancy is not accurate; and impregnation and conception need not necessarily be coincident.

The signs of pregnancy are of the utmost importance to the medical jurist. He may be called upon to pronounce upon the virtues of a female, to sustain or rebut a plea for divorce, to determine whether a capital sentence shall be carried out, or to determine whether it is possible that a man who has never lived with a woman shall be the father. The medical jurists classify the signs of pregnancy as uncertain or certain; it is the former which are most regarded by the public, but the latter are alone of probative value to the jurist. The usual and uncertain signs are the cessation of the monthly flow, nausea, a diminution of sensibility, a return to the physiological monthly flow of a secondary area around the nipple, enlargement of the breasts, increased size of the abdomen, the formation of a tumour in the womb, quickening, and the motions of the foetus. Also uncertain are the uterine souffle, which is the result of the increased blood circulation synchronous with the maternal pulse and ballottement or the examination for a floating tumour in the abdomen between the fifth and eighth months of pregnancy. The certain signs of pregnancy are the foetal limbs palpated through the abdomen by the physician, the pulsations of the uterine arteries visible or felt in the stethoscope, the pulsations being much quicker and not synchronous with the maternal pulse. This latter is inapplicable before the fourth month of gestation.

7. **Parturition.**—The imminence of the process of parturition is of comparatively little interest to the medical jurist; but the signs of recent delivery are of great importance. These signs are the bruised and reddened state of the external genitals, relaxation and dilatation of the vagina and womb, the existence of a peculiar vaginal discharge known as the lochia, a relaxed and fissured condition of the abdominal walls, a peculiar aspect of the countenance, and the distended state of the breasts due to the secretion of milk. The lochial discharge is the most characteristic sign. All the signs may disappear within ten days of delivery, though this is not usual.

Connected with parturition, the question of viability (potency for life) of the child is not unimportant. After the intra-uterine age of seven months is reached a child is certainly viable. The period at which the foetus has a chance of life, but may not be born, is perhaps the nearest approximation. The viability of a child is judged by its size and weight, its general state of development; the state of the skin, hair, and nails; its strength or feebleness, the ability or inability of the lungs to perform the act of breathing. The determination of viability has important bearings upon the crime of infanticide.

In the case of succession to property the meaning of "born alive" is different from the meaning of the same expression used respecting infanticide. In questions of tenancy by the curtesy (q.v.) it has been decided that every kind of motion of the child, as a twitching and tremulous motion of the lips, is sufficient evidence of live-birth. By the French code, however, no child that is born alive can inherit, unless it is born viable. As regards infanticide, proof of a conscious and complete existence of the child is demanded before it is birth is admitted.

The subject of superfoetation and superfecundation, or the possibility of two conceptions having occurred resulting in the birth of twins, is one which has given rise to much controversy. There is much, however (e.g. the existence of a double or bifid uterus), to countenance the view that a double conception is possible.

8. **Monsters and Hermaphrodites.**—To destroy any living human birth, however unlike a human creature it may be, is to commit a crime. Blackstone states that a monster which hath not the shape of mankind hath no inheritable blood; but the law has not defined a monster, nor what constitutes a human form.

The same author states that if, in spite of deformity, the product of birth has human shape, it may be an heir. Hermaphrodites are beings with malformations of the sexual organs, simulating a double sex. Physicians do not admit, however, the existence of true hermaphrodites with double perfect organs, capable of performing the functions of both sexes.
9. Paternity and Affiliation.—These are often matters of great
doubt. A considerable time may elapse between the absence or
death of a father and the birth of his reputed child. As has
already been said, three hundred days is the utmost limit to
which physiologists would extend the period of utero-gestation.
This subject involves questions respecting children born during
a second marriage of the mother, posthumous children, bastardy,
and alleged cases of posthumous children.

10. Presumption of Survivorship.—When two or more persons
perish by a common accident, when a mother and her new-born
child are found dead, and in a few analogous cases, important
civil rights may depend upon the question which lived the longest;
and great ingenuity has been displayed in elucidating the disputes
which have arisen in the law courts in such cases.

11. Maladies exempting from Discharge of Public Duties
frequently demand the attention of the medical man. He may
be called upon to decide whether a man is able to undertake
military or naval service, to act as a jurymen without serious risk
to life or health, or to attend as a witness at a trial.

12. Feigned and Simulated Diseases often require much skill
and caution in order to detect the imposture.

13. The Signs of Death.—The determination of the actual
death of a person is more difficult in tropical countries, where the necessity for speedy interment may involve
a risk of burial alive. Such an accident cannot well occur where
a medical man confirms the existence of death, and in the United
Kingdom, where burial rarely takes place before the lapse of
forty-eight hours, such changes usually occur in the body as to
render any error practically impossible. Within a varying period,
usual not more than twelve hours, the body becomes
rigid, owing to the development of rigor mortis or post mortem
rigidity. The blood, which during life is equally distributed
throughout the body, gravitates to the most dependent parts
and develops a discoloration of the skin which is known as
post mortem lividity or post mortem staining. At a variable
period of time, dependent on the cause of death, also the tempera-
ture and moisture of the air to which the body is exposed, de-
composition or putrefaction sets in. These changes after death
are of great importance, not only as affording certain proof
of death, but also because they furnish valuable information
as to the probable time at which it occurred, and from the fact
that they may alter or destroy evidence as to the cause of
death.*

14. Insanity or Mental Alienation.—A medical man may be
required to give evidence in any of the law courts, civil, criminal
or ecclesiastical, before commissions de lunatico inquirendo, or
before a magistrate, as to the sanity or insanity of an individual;
and he may have to sign certificates of unsoundness of mind with
the view of providing for the safe custody and proper treatment
of a lunatic. Hence he must be familiar with the chief forms
of insanity (see Insanity), and be able to distinguish and treat
each of these. He will also be required to detect feigned insanity,
and to examine persons charged with crime with the view of
preventing real lunatics from being treated as criminals.

II.—INJURIES TO THE PERSON

1. Deformation.—The signs of deformation are obscure and
uncertain; and it is rather by the coexistence of several of the
usual marks than the existence of any one sign, that any just
conclusion can be arrived at.

2. Robbery.—This crime consists in the carnal knowledge of a
woman by forcible means against her will. The proofs of rape
are often taken away from the conscience of the woman's story, mainly depend on the
presence of marks of violence, stains, &c. In all charges of rape,
the woman and her assailant should be examined as soon as
possible by a medical man, but such examination, it is important
to remember, can only be carried out with the free consent of the
party to be examined. It is to be noted that according to English
law the slightest degree of penetration is sufficient to constitute
the crime of rape.

3. Mutiny.—This may consist in the cutting or maiming of
any member; castration is the most important, and perhaps but
rarely effected as a crime. Self-mutilation, giving rise to false
accusations, is occasionally resorted to.

4. Common Assault.—This consists in unlawfully
pressing the expulsion of the contents of the gravid uterus
at any period short of full term. It must be noted that while this
definition may be held to recognize the induction of premature
labour by medical men in certain circumstances, yet, when the
operation is necessary, a medical man should always provide
himself with possible misconstruction of his action (i.e. criminal
intent) by having a consultation with another practitioner. The
means employed in criminal abortion to procure the desired
result may be classed under three heads: (1) general violence to
the body, (2) administration of drugs supposed to have aborti-
facient qualities, (3) instrumental interference with the contents
of the uterus. Among the drugs frequently employed for the
purpose, although by no means always successfully, are ergot,
strong purgatives, iron, rue, pennroyal, savin.

5. Homicide.—The legal sense of the term homicide excludes
such injuries as are the result of either accident or of suicide. It
embraces murder or willful homicide, manslaughter or culpable
homicide, casual homicide, and justifiable homicide.

Ordinary homicide may be accomplished by several modes
that may sometimes be ascertained by examination of the body,
e.g. poison.

As a preliminary, in all cases of homicide, it is the duty of the
medical jurist in the first place to ascertain the fact of death, and
to distinguish between real and apparent death; and then to
determine, if possible, the period at which death took place.

Infanticide, or child murder, is by the British law treated with
the same severity as the murder of an adult. Indeed infanticide
as a crime distinct from murder has no legal recognition. Practi-
cally this severity defeats itself, and hence an alternative charge
of concealment of birth in England, or concealment of pregnancy
in Scotland, is usually preferred in such cases.

The iniquity of the old law which threw the onus of proof of still-
birth on the mother no longer exists, and the law demands
strict proof of live-birth at the hands of the prosecution. Hence
the subject involves nice points of forensic medicine. The child
must be proved to have arrived at the period when there was a
probability of its living (proof of viability); and as the establishment
of respiration is necessary to prove live-birth the evidences of
this must be carefully investigated. The size and position of the
lungs, and the state of the vessels concerned in foetal circulation,
must be carefully noted. The foetal lungs are dark, dense and liver-
like in appearance and consistence, and sink when immersed in
water; whilst the full, round, and soft lungs, if penetrated,
will float in water even after subjection to firm pressure in the
hand. Care must be taken, nevertheless, to exclude buoyancy of the lung
due to putrefaction; in this case the air may be expelled by gentle
compression, or previously the importance of a film now sinks in
water. It is impossible, however, to distinguish certainly between a
lung naturally inflated and a one artificially insufflated.

It must be borne in mind that, although live-birth cannot be
ascertained in the absence of signs of respiration, the presence of these
signs is not proof of live-birth in the legal sense of the term. The
law demands for live-birth a separate existence of the child after
delivery; and breathing may take place whilst the child is still either
wholly or partially within the passages, and in some special
cases whilst still within the uterus itself.

When proofs of respiration—i.e. to be such an extent as to
leave no doubt as to live-birth—have been found, the cause of death
is then either natural or due to exposure, or to the subsequent
sedative treatment. Wounds, and other forms of injury, must
be sought for. There may be signs of strangulation, suffoca-
tion, puncture of the fontanelles and consequent injury to the brain,
the administration of a poison, or other means of procuring death.
It must be borne in mind that some of these may be brought
about by one or the other means. Thus strangulation may
arise from natural and unrelied pressure of the navel-string
on the neck of the child; suffocation from immersion of the face of
the child in the maternal discharges, or by pressure of clothes on
the head which may result from unnatural handling; or neglect to
untie the navel-string, or the infant may perish from exposure to
cold.

In the case of exposed infants it is important to ascertain the real
mother. As such exposure usually takes place soon after birth,
the position of the age of the infant with the signs of recent
delivery in the suspected mother is the best method of proving the
relation.
Death from Asphyxia. Among the forms of violent death due to this cause are drowning, hanging, strangulation, garroting, smothering, and suffocation. The mode used is that which is attended with the expansion of the chest walls, as when persons are crushed together during a panic in a fire, breathing poisonous gases, such as carbonic acid or carbonic oxide. Suicide and accidental death from these causes are still more common.

Drowning is thought to produce death occasionally by the suddenness of the shock causing suspension of the functions of circulation and respiration. The body itself is not damaged. The true cause of death appears, however, to be by the circulation of unoxygynated blood through the brain acting as a poison upon that organ; and this is attended with all the phenomena of asphyxia, as in suffocation. The phenomena attending asphyxia are as follows. As soon as the oxygenated blood ceases to be supplied to the brain, the vital processes of all the organs of the body fall into abeyance. The breathing movements become much more frequent; both the inspiratory and expiratory phases are exaggerated, the supplementary respiratory muscles are brought into a state of insensibility, and the blood becomes more and more venous, the respiratory movements continue to increase both in force and frequency. Very soon the expiratory movements become more marked than the inspiratory, and the victim must which can in any way assist in expiration is brought into play. The orderly expiratory movements culminate in expiratory convulsions; these violent efforts speedily exhaust the nervous system, and the convulsions suddenly cease and are followed by a state of profound calm. In this condition of insensibility, no active movements have ceased, and all the muscles of the body are flaccid and quiet. But at long intervals lengthened deep inspiratory movements take place; then these movements become less frequent; the body becomes less marked, the arm breath becomes more and more a long gas, which becomes at last a convulsive, shrinking of the whole body; and with extended limbs and a straightened trunk, with the head thrown back, the mouth widely open, the face dyspnoeic or extremely faint when inact, the victim may be found to be looking for air admission. The phenomena are not all observed except in cases of sudden and entire exclusion of air from the lungs. In slow asphyxia, where the supply of air is gradually diminished (e.g. in drowning), the phenomena are less striking. Here, however, the peculiarity is that the appearances of the body after death from drowning are various. There may be pallor of the countenance, or this may be livid and swollen. The air passages are filled with frothy mucus, and there may be some water in the stomach. The ends of the fingers are often excoriated from grasping at objects; and weeds, &c., are sometimes found grasped in the hands. The distinction between murder and suicide by drowning can rarely be made by examination of the body alone, and it is usually decided from statements or marks of a struggle. Attention must also be paid to the existence of wounds on the body, marks of strangulation on the neck, and the like.

Hanging may result in death from asphyxia, or, as is more particularly the case in judicial hanging, some injury is inflicted on the upper portion of the spinal cord, resulting in instant death. The ordinary appearances of death from asphyxia may be found: dark fluid blood, congestion of the brain, intensely congested lungs, the right cavities of the heart, lungs, and great vessels empty, and the great general engorgement of the visera. Ecchymosis may be found beneath the site of the cord, or a mere parchmenity appearance. There may even be no mark of the cord visible. The mark, when present, is often small and not in the shape of a triangle. The fact that a body may be suspended after death, and that if this be done speedily whilst the body is still warm there may be a post-mortem mark un distinguishable from the mark observed in death from hanging, is well to be remembered. Furthermore, additional marks, such as those of a false asphyxia, which have already been detailed. On post-mortem examination the surface of the lungs is found covered with minute extravasations of blood, known as punctated ecchymosis. The markings may occasionally be over the neck, or by forcibly compressing the windpipe (throttling). Hence there may be either a circular mark round the neck, not so oblique as after hanging, or the marks of the fingers may be found as after hanging. There may or may not be lacerations of the larynx and windpipe may be broken. The mark of the ligation is often low down on the neck. The signs of asphyxia are present in a marked degree.

Suffocation may occur from the impaction of any substance in the glottis, or by covering up the mouth and nose. It is frequently of accidental origin, as when substances become accidentally impacted in the glottis. This may be due to the swallowing of inanimate objects, such as those of pure asphyxia, which have already been detailed. On post-mortem examination the surface of the lungs is found covered with minute extravasations of blood, known as punctated ecchymosis. The markings may occasionally be over the neck, or by forcibly compressing the windpipe (throttling). Hence there may be either a circular mark round the neck, not so oblique as after hanging, or the marks of the fingers may be found as after hanging. There may or may not be lacerations of the larynx and windpipe may be broken. The mark of the ligation is often low down on the neck. The signs of asphyxia are present in a marked degree.

In the United Kingdom this last form of death usually results accidentally from an escape of lighting gas, the danger has much been increased in many towns owing to the addition of carburetted water-gas to the ordinary supply. Carbonic oxide gas is contained in ordinary lighting gas to the extent of about 6 to 8%, and the carburetted water-gas contains about 28%, and when mixed with ordinary lighting gas the percentage of carbonic oxide is thus very much increased. As a mode of assassination it is seldom employed, but is frequently resorted to on the continent of Europe by suicides, charcoal fumes being commonly used for the purpose.

6. Death from Starvation.—Cases occur in which it is important to distinguish this from other modes of death. In such cases the skin becomes harsh and dry, and may acquire a peculiar odour; the subcutaneous fat disappears; the gums shrink away from the teeth; the tongue and mouth become dark-coloured and dry; the eyes are bloodshot; the intestines become thin and their coats translucent; the gall-bladder is distended. The period of total abstinence from food required to kill an adult is unknown, and greatly depends upon whether there be access to liquid. In some cases persons have been able to subsist on little or no nourishment for long periods, the body being in a state of quasi-hibernation.

5. Death from Extremes of Temperature.—(1) Death from cold is not uncommon observed in the British Isles. A portion only of the body, as the extremity of a limb, may perish from extreme cold. After the first sensation of tingling experienced on exposure to severe cold, loss of sensation supervenes, with languor and an irresistible propensity to sleep. The tendency to this forms an extreme danger in such cases. (2) Death from extreme heat usually occurs in the form of burning and scalding, attended with destruction of a large portion of the cutaneous structures. Here the cause of death is obvious. The human body is capable of exposure to very hot air—as is seen in Turkish baths—for a considerable period with impunity. Sunstroke is a cerebral affection brought on by too great exposure to a hot atmosphere, especially whilst undergoing fatigue.

8. Death by Lightning.—Lightning or an electric current may cause instant death. No visible marks of the effects of the electric current may be left, or the body may be singed or discoloured, or the skin may be perforated at one or two spots. These include in a medico-legal sense not only those characterized as incised, punctured, contused, lacerated, stab wounds, but also burns, injuries produced by firearms, fractures, dislocations, &c. One of the chief questions which have to be decided in all forms of violent death is whether it was the result of accident, suicide or murder. In cases of fatal wounding, among the points to be noted, which will help to decide the question, are the situation, direction and extent of the wound, the position in which the body and any weapon may be found, together with the presence and distribution of any blood marks and the signs of a struggle. In wounds caused by firearms the injury, if suicidal, is usually situated in a vital and accessible part of the body, the temple, mouth, and chest being the favourite situations; but such an injury also presents, as a rule, the characteristic appearances resulting from the discharge of the weapon close to the body, viz. besides the wound of entrance of the bullet, there are singeing of the cuticle and hair, and blackening of the area immediately surrounding the wound, from particles of un consumed powder being driven into the skin and from the smoke of the discharge. These effects are naturally not produced when the weapon is discharged at a distance exceeding 2 or 3 ft., as usually happens in cases of homicidal shooting. They may also be wanting in undoubted suicidal wounds produced by revolvers and cartridges filled with ammorcite or other smokeless powders. Death from burning is generally accidental, very rarely suicidal, and when homicidal is usually employed to conceal traces of other violence inflicted upon the body. In large conflagrations death is not always due to burning. Charred bodies may be found presenting various injuries due to the fall of beams, crushing, the trampling of others trying to escape, &c., or fractures and lacerations may be due simply to the action of the heat. Death may result from such injuries, or from suffocation by the gases of combustion, before the victim has been driven away by the instantaneous combustion of the body has been stated to occur, but the evidence upon which the cases rest is not well authenticated.

Punctured wounds or stab require minute attention; for there have been instances in which death has been produced by an instrument so small as a pin thrust into a vital part. Wounds of the head are always dangerous, especially if the blow has been severe. The person so wounded may die without division of the skin, or fracture...
of the bones, as happens in what is known as concussion of the brain. Contusions which do not divide the skin may fracture the skull; or the inner table of the skull may be fractured without the outer being broken or depressed. Even wounds of the scalp may prove fatal; but wounds of the face are more generally fatal than wounds of the head, as they are more dangerous than cuts, as more likely to excite fatal inflammation. When the brain and its membranes are injured, all such wounds are generally fatal. Wounds of the face and scalp are, however, more apt to be neglected, as they afford less facility for the191

production of serious inconvenience. Wounds of the neck are always serious whenever more than the skin is divided. The danger of opening large blood-vessels, or wounds important nerves, is increased by injuries to the parotid gland or branch of the external carotid artery. An incision immediately fatal, from the entrance of air into the vessel, and its speedy conveyance to the heart. A blow on the neck has instantly proved fatal, from injury to an important nerve, generally the phrenic, and the interior jugular or subclavian vein. The wound of the abdomen, when they do not completely penetrate, may be considered as simple wounds, unless when infected with great force, so as to bruise the contents of the abdominal cavity; in that case they may produce death by an obstruction of the arteries, the rupture of the veins, or sometimes happens from blows or kicks upon the belly. Wounds injuring the peritoneum are highly perilous, from the risk of severe contamination. Wounds of the stomach or intestines, or of the gall-bladder, or kidneys, or bladder, when they penetrate the one or the other, may produce the peritoneal cavity producing fatal inflammation. Wounds of the liver, spleen, or kidneys are generally soon mortal, from the great vascularity of those organs. Wounds of the extremities, when fatal, are generally so complicated by the excreta, or from the consequent of inflammation and gangrene, or from the shock to the system when large portions of the limb are forcibly removed, as in accidents from machinery, and in wounds from firearms.

Blood Stains.—The examination of blood stains is a frequent and important operation in criminal charges. Blood stains when fresh and abundant can be recognized without difficulty, but when old, or after being acted upon by certain substances, their identity is not readily determined.

The tests which may be applied to a suspected stain consist of:

1. The microscopic test. A portion of the stain is soaked in a drop of spirits of turpentine. If the stain is blood, the red corpuscles without altering their characteristic appearance. Such fluids are solutions of glycercine and water of a specific gravity of 1.028 or 30% caustic potash. The recognition of blood corpuscles affords a certain test of their purity.

2. Heat applied to a solution obtained by soaking some of the stain in cold water. A blood solution is red, and loses its red colour on application of heat, while at the same time a buff-coloured precipitate of albumin is deposited. A drop of the prepared tincture of guaiacum and then some ozenic ether or peroxide of hydrogen to the stain, a blue colour is obtained if blood be present. Many other substances, however, give the same reaction. (c) If, however, after adding a solution of common salt and some glacial acetic acid be added, and the liquid is heated to ebullition and allowed to evaporate away, small brown rhomboidal crystals—haematin crystals—will be found to have formed, and will be decomposed upon the addition of alkali.

3. Spectroscopic test. A solution of blood obtained from a stain will now be found to have one of two dark bands between Fraunhofer's lines D and E (oxyhaemoglobin) and one broad dark band is seen (reduced haemoglobin). On adding caustic potash to a solution of blood, alkaline haematin is formed, and this again is transformed on the further addition of ammonium sulphide into reduced haematin or haemochromogen, which gives a very characteristic spectrum of bands. The formation of these three different spectra from a red-coloured solution is characteristic of blood. Old blood stains are insoluble in water, whereas recent stains are readily soluble in cold water, yet not in boiling water. The application of boiling water or washing with soap tends to fix or render blood stains insoluble. Vegetable dyes may likewise give red solutions, but they may be distinguished from blood by the addition of ammonia, which alters the colour of the former, but rather intensifies the red colour of a blood solution.

The differentiation between human blood stains and those produced by the blood of other animals, more especially domestic animals, is a matter of great importance to the medical jurist. When the blood stain is fresh, measurement of the corpuscles may decide the question, but in the case of dry and old stains it is impossible of making the distinction. A method has been discovered, however, which enables the distinction to be made not only between human blood and that of other animals (with the exception of Simia), but also between the bloods of different animals. The method depends upon the fact that if an animal (A), such as a dog or rabbit, is inoculated with the blood or serum of another animal (B), then the blood or serum of A is found to produce a specific reaction (namely, the production of a cloudiness or precipitate) in the serum of B, but not in the serum of the blood of a similar animal to B, and that species of animal only. If, therefore, human blood serum is injected into an animal, its blood after a time affords an "anti" serum which produces the specific reaction only in human blood serum, and not in those from the blood of other animals.

10. Poisoning.—There is no exact definition of a poison (g.v.). Popularly, substances which destroy or endanger life when swallowed in small quantity are called poisons, but a scientific definition would also include many substances which are injurious to health in large doses or only after repeated administration, and which act not only when swallowed, but also when taken into the system through other channels, e.g., the skin or the lungs. The branch of science which relates to poisons, their nature, methods of detection, the symptoms produced by them, and treatment of poisoning, is called Toxicology, and is one of the most important subjects included under the term Medical Jurisprudence.

The medical evidence in cases of poisoning rests upon—(1) the symptoms produced during life; (2) the post mortem appearances; (3) the chemical analysis and detection of the substance in the body, or in the excretions and vomited matters, or in the stomach; (4) comparison of the blood of a similar animal to the poison with that of other poisonous animals; (5) the poison being in those formed from the blood of other animals; (6) the poison being in those formed from the blood of other animals by the operation of different agents.

Poisoning (see also ADULTERATION).—Foods may prove noxious from a variety of causes: (1) The presence of metallic poisons, as in peas artificially coloured with copper salts, in tinned foods from dissolved tin salts, &c. (2) The contamination of any food with the specific germ of disease, as for example, milk infected with the germ of enteric fever. (3) The presence in meat of parasites, such as the Trichina spiralis, or of disease in animals, capable of transmission to man, such as tuberculosis, or the presence of poison in the flesh of animals which have fed on substances harmless to them but poisonous to human beings. Grain may be infected with parasitic fungi of a poisonous character, as for example, Claviceps purpurea, causing epidemics of ergotism. (4) Foods of various kinds may contain saprophytic bacteria which elaborate certain poisons, either before or after the food is taken. It is chiefly in relation to food-poisoning from the last-mentioned cause that our knowledge has been increased in recent years.

Many cases of food-poisoning, previously of mysterious origin, can now be explained. For example, in 1868, Balfour and Maclean produced cases accompanied by severe symptoms in which every thing they ate produced the same symptoms; in these cases, the symptoms and intoxication were set up by bacterial toxins, for which they give rise to—toxalbumoses, tomatumes, toxins—by splitting up proteid substances. It is not necessary that the food should show evident signs of putrefaction. It may not do so, and yet on being eaten produce violent symptoms of gastro-intestinal irritation almost immediately, followed by various nervous symptoms. In such cases a chemical poison, developed by putrefactive bacteria before the food was eaten, quickly acts upon the system. On the other hand, symptoms may not appear for many hours after ingestion of the food, and then come on suddenly and with great
severity—there has been a period of incubation. In such cases the food when swallowed has contained the bacteria, but the poisonous toxin has been elaborated by them afterwards in the system during the period preceding the onset of symptoms. In both varieties of poisoning the symptoms are similar, consisting of gastro-intestinal irritation—diarrhoea and pain in the abdomen—together with great prostration, fever, muscular twitches, disturbances of vision, delirium and coma. The varieties of meat which have most frequently given rise to poisoning (Botulinus) are pork, ham, veal, sausages and various kinds of fished meat. Pig flesh appears to be specially liable to become infected. A point of considerable interest, which has sometimes given rise to doubt as to the poisonous character of meat in certain instances, is, that the same food may be poisonous at one time and harmless at another. Thus it may be harmless when freshly prepared, cause fatal effects if eaten a day or two afterwards, and shortly after that again prove perfectly innocuous. This is explained by the fact that the toxic substance is only developed if the food is left to ferment after development are still further split up by the bacteria into other bodies of a harmless nature.

In some fish—e.g. Trachinus draco, or sea trawer—the poison is a physiological product of certain glands. In others the poison is not, as in the family Scombridae, to which the disease-gastric symptoms have been attributed. In the United Kingdom the poisonous effects produced by fish are due to bacterial agency after death, and instances have occurred from the eating of herrings, mackerel, dried salt codfish, caviare, tinned salmon and tinned sardines. Shellfish may produce poisonous effects from putrefactive changes or from the development in them (oysters and mussels) of ptomaines. Brigger discovered a ptomaine in poisonous mussels to which he gave the name of Oceanin. It was observed that oysters and mussels may become contaminated with the organism of typhoid fever if placed in specially polluted water, and thus transmit the disease to human beings. Milk, as already stated, may be contaminated with Oceanin. In the course of the 17th century several new cases of poisoning by milk were known. It may also contain substances of bacterial origin, which are possibly the cause of infantile diarrhoea, and others, having a fatal effect upon adults. Cheese has frequently caused poisoning. Vaughan discovered a substance in milk and cheese called tyrotoxin, but there are other toxic substances of bacterial origin sometimes present in cheese to which poisonous effects have probably been due. Mushrooms—poisoning results from the eating of poisonous fungi in mistake for the edible mushroom. The poisonous element in most cases is a toxin which was contained in the fungus Amanita muscaria, or phallus in Amanita phalloides.

**History of Forensic Medicine**

The true origin of medical jurisprudence is of comparatively recent date, although traces of its principles may be perceived in remote times. In the ancient Greeks the principles of medical science appear only to have been applied to legislation in certain questions relating to legitimacy. In the writings of Galen we find, however, remarks on the differences between the foetal and the adult lungs; he also treats of the legitimacy of seven months' children, and discusses feigned diseases. Turning to Rome, we find that the laws of the Twelve Tables fix three hundred days as the extreme duration of utero-gestation. It is doubtful whether the Roman law authorized medical inspections of dead bodies. In the code of Justinian we find De statu hominum; De poenis et manumissis; De scoriiis; De insipciendo venere custodiendoque portu; De muliere quae peperit undecimo mense; De impotentia; De hermaphroditis—titles which show obvious traces of a recognized connexion between medicine and law. It was not, however, by the testimony of living medical witnesses that such questions were to be settled, but on the authority of Hippocrates.

Medical jurisprudence, as a science, dates only from the 16th century. In 1507 the bishop of Bamberg introduced a penal code in which the necessity of medical evidence in certain cases was recognized; and in 1523 the emperor Charles V. persuaded the Diet of Ratisbon to adopt a uniform code of German penal jurisprudence, in which the civil magistrate was enjoined in all cases of doubt or difficulty to obtain the evidence of medical witnesses,—as in cases of personal injuries,infanticide, pretended pregnancy, simulated diseases, and poisoning. The true dawn of forensic medicine dates, however, from the publication in 1553 of the Constitutio criminalis carolina in Germany. A few years later Weier, a physician, having undertaken to prove that witches and demonsiacs are, in fact, persons subject to hypochondriasis and hysteria, and should not be punished, aroused popular indignation, and was with difficulty rescued from the flames by his patron, William duke of Cleves.

At the close of the 16th century Ambrose Paré wrote on monsters, on simulated diseases, and on the art of drawing up medico-legal reports; Pineau also published his treatise on virginity and defloration. About the same time as these stimuli to the study of forensic medicine were being made known in Paris, the first systematic treatise on the science appeared in Sicily in the form of a treatise De relationibus medicorum by Fidele. Paolo Zacchia, the illustrious Roman medical jurist, moreover, published from 1621 to 1635 a work entitled Quaestiones medico-legales, which marks a new era in the history of the science—a work which displays an immense amount of learning and sagacity in an age when chemistry was in its infancy, and physiology very imperfectly understood. The discovery of the circulation of the blood by Harvey soon followed, and gave a new impetus to the study of those branches of forensic medicine having direct relations to physiology; and to Harvey we owe the idea how to apply Galen's observations on the differences between the foetal and the adult lungs to the elucidation of cases of supposed infanticide. About this time, too, Sitz published two treatises, on the signs of virginity and on the examination of wounds respectively. In the former he contended that the hymen was the real mark of virginity; but this was denied by Augenio and Cassendi. In 1663 Thomas Bartholin investigated the period of human uterine gestation, a subject which had engaged the attention of Aristotle. He also proposed the "hydrostatic test" for the determination of live-birth—a test still in use, and applied by observing whether the lungs of an infant float or sink in water. J. Swammerdam explained the rationale of the process in 1677; but it was not till 1682 that it was first practically applied by Jan Schreyer.

Germany, ever the leader in questions of forensic medicine, introduced the first public lectures on medical jurisprudence. Michaelis gave the first course about the middle of the 17th century in the university of Leipzig; and these were followed by the lectures of Bohn, who also published De renunciatione vulnerum; cui accesserunt dissertatioes binae de partu enecato, et an quis vivos mortuusque acuis submersus, strangulatus, aut in manus fuert, and De officiis medici duplicis, clinici et forensis. Welsh and Auman wrote on the fatality of wounds, and Licetus on monsters.

From the time of Ambrose Paré the mode of conducting investigations in forensic medicine had attracted attention in France; and in 1603 Henry IV. authorized his physician to appoint persons skilled in medicine and surgery to make medicolegal inspections and reports in all cities and royal jurisdictions; in 1693, difficulties having arisen, Louis XIV. created hereditary royal physicians and surgeons for the performance of like duties. These, having become a corrupt and venal body, were suppressed in 1790. The only works on forensic medicine which appeared in France during the 17th century, however, were Gendry's Sur les moyens de bien rapporter à justice and Blégny's Doctrine des rapports en chirurgie. At the beginning of the 18th century the latter was superseded as a text-book by Devaux's L'Art de faire des rapports en chirurgie. Valentiou followed with two works, which were finally incorporated in his Corpus juris medicolegale, which appeared in 1729. This work is a valuable storehouse of medicolegal information, and a summary of the knowledge of the time.

Professorships for teaching the subject were founded in the German universities early in the 18th century, and numerous treatises on forensic medicine were published. Teichmeyer's Institutiones medicinae legalis long formed the text-book of the subject; and Alberti, professor of legal medicine at Halle, in his Systema gave to the world a most complete and laborious treatise on the science. His industrious collection of facts renders his works a precious mine of information. Indeed towards the close of the 18th century the Germans were almost the only cultivators of legal medicine. But in France the celebrated case of Villeblanche attracted attention to the subject, and called forth Louis, who in a memoir on utero-gestation attacked with powerful arguments the pretended instances of protracted pregnancy, and paved the way for the adoption in the Code Napoléon of
three hundred days as the limit of utero-gestation, a period in precise accordance with the ancient Roman law of the Twelve Tables. Later also wrote on the effect of hanging, and pointed out the mode by which we may distinguish suicide from suicide under such circumstances. It is he who is credited with having been the first in France to publicly teach the just application of medical knowledge to jurisprudence. Fodéré’s celebrated Traité de médecine légale appeared in 1798, and makes a new era in the annals of legal medicine.

No British author wrote systematically on forensic medicine till 1788, when Dr Samuel Farr published a short treatise on the Elements of Medical Jurisprudence; but this was merely an abridgment of an earlier work of Fazelius. Previous writers—as Mead, Munro, Denman, Percival and the two Hunters—had, however, dealt with fragments of the subject; nevertheless the science as a whole was little appreciated or recognized in this country during the 18th century.

In the 19th century France took the lead; and the institution of three professorships of forensic medicine at the end of the 18th century produced excellent fruits. In 1814 Orfila, a Spaniard by birth, who was naturalized in France, published his Toxicologie, a work which revolutionized this branch of medical jurisprudence, and first placed the knowledge of poisons upon a scientific basis. Since the time of Orfila, France has never ceased to have one or more living medical jurists, among the most recent of whom we must enumerate Tardieu, whose treatises on abortion, on poisons, on wounds, &c., are justly celebrated. Germany too industriously pursued the subject, and Casper’s great work on forensic medicine will ever remain a classic in the science. In Russia Dragendorff greatly contributed to our knowledge of poisons.

Though forensic medicine may be said to have been entirely neglected in England till the beginning of the 19th century, its progress has been no way unimportant; and the subject now forms a recognized and obligatory portion of medical study. The first lectures delivered in Great Britain were given in the University of Edinburgh in 1801 by the elder Dr Duncan; and the younger (Professor Duncan) was the first in this country to apply Taylor’s Principles and Practice of Medical Jurisprudence (1906, edition, by F. J. Smith), the same author’s Elements of Medical Jurisprudence, Dr Guy’s Forensic Medicine, and Ogston’s Lectures on the Practice of Medical Jurisprudence, which were given in the middle of the 19th century at Edinburgh.

The separate memoirs of Taylor, Christie, Cuy and others are also storehouses of facts and deductions in the science. America, too, has not been behindhand in the race. F. Wharton and M. Still’s Manual, Wormley’s Toxicology, and the works of Beck and Reese have furthered the study of the science.

See also Dixon Mann, Forensic Medicine and Toxicology (London, 1902); Wynter Blyth, Poisons: their Effects and Detection (London, 1899); and Paul Duhem’s Médécine légale (Paris, 1888). In Germany, too, the science has been equally advanced. The works of Beck and Reese have been followed by those of the German professors. See also the works of Beck and Reese.

latter,
although
a
member
of
the
greater
gilds,

had
joined
the
lesser
and
sought
to
be
at
their
head,

in
order

to
lay
the

foundation
of
his
own
power
and
that
of
his
kindred
by
attacking
the
Albizzi,
who
were
the
leading
men
of
the

greater
gilds.

The

victory
of
the

Ciompi,
however,
was
brief,
for
the

excesses
of
the

lower
gilds

brought

about

a reaction,
in

which
they
were
crushed,
and
Michele
di
Lando
sent
into
banishment.

Nevertheless
the
lesser
gilds
had

gained
some
ground
by
this
riot,
and
Salvatore
dei
Medici

the
great
popularity
at
which
he
had
aimed.
His
policy
during
that
time
had

taken
the

tracel
possible
road
to
power
in

liberty-loving
Florence.

This
was
the
road
henceforth
pursued
by
the

Medici.

On
Salvatore’s
death
in
1388
the
Albizzi
repossessed

themselves

do

the

government,
and
conducted
the
wars
of
the

republic.

Vieri
dei
Medici,
who
seems
to
have
been
the
next

head
of
the
family,
understanding
the

temper
of
the

times,
abstained
from
becoming
a
popular
leader,
and
left

it
to
his
successors
to

prosecute
the

task

under
easier
conditions.

Then,
in
the

second

quarter

of
the

19th
century,

another

branch

of
the

family
arose,
and

became
its
representative.

Indeed
Giovanni
may
be
considered
the
actual
founder
of
Medicean
greatness.

He
took
little
part
in
political
affairs,
but
realized
an
immense
fortune
by
trade—

establishing
banks
in
Italy
and
abroad,
which
in

his
successor’s

hands
became
the
most
efficient
engines
of
political
power.

The
Council
of
Constance
(1414–1418)
enabled
Giovanni
dei
Medici
to
realize
enormous
profits.

Besides,
his
ancestor
Salvatore,

he
was
a
constant
supporter
of
the
lesser
gilds
in
Florence.

Historians
record
his
frequent
resistance
to
the
Albizzi
when

they

sought
to

oppress
the
people
with
heavier
taxation,
and
his

endeavours
to

cause
the

chief

weight
to
fall
upon

the

richest

classes.
For
this
reason
he
was
in
favour
of
the
so-called
law
castissi,
which,
by
assessing
the
property
of
every

citizen,

prevented
those
in
poverty
from
arbitrarily
imposing
taxes
that
unequitably
encumbered
the
people.

In
this
way,
and
by
liberal
loans
of
money
to
all
who
were
in
need
of
it,
he
gained
a
reputation
that
was
practically

the

foundation-stone
of
the

grand
family

edifice.

Giovanni
dei
Medici

died
in
1420
leaving
two
sons,

Cosimo
(1380–1464)
and
Lorenzo
(1395–1446).

From

the
former

he

acquired

the

branch

that

held
absolute

power

for

many

centuries

over
the

nominal

republic
of
Florence,
and
gave

to

Italy

popes
like
Leo
X. and

Clement
VII.

On
the

extinction
of
this
elder
line
in
the
16th
century,
the
younger
branch

derived
from

Lorenzo,

Cosimo’s
brother,

seemed
to

acquire

new
life,
and

for

two

centuries

supplied
duchies
to

Tuscany.

Cosimo,
nursed
Cosimo
the
Elder,
to
distinguish
him
from

the

many

others

bearing
the

same

name,
and

honoured

after

his
death
by
the
title
of
pater
patriae,
first

succeeded

in

solving

the

strange

problem

of

becoming

absolute

ruler

over

a

republic
eenviously
jealous
of
its

liberty,

by

holding
any
fixed
office,

without

suppressing

any

form

of

government,

and

always

preserving

the
appearance
and
demeanour
of
a

private

citizen.

Born
in
1389,

he
had
reached
the
age
of
forty
at
the
time
of
his
father’s
death.

He
had
a
certain
amount
of
literary
culture,
and
throughout

his
life
showed
much
taste
and
an
earnest
love
both
for

letters
and art. But his father had mainly trained him to commerce, for which he had a special liking and aptitude. He was devoted to business to the day of his death, and like his forefathers derived pecuniary advantage from his friendly relations with the papal court. He accompanied Pope John XXIII. to the Council of Constance, transacted a vast amount of business in that city, and made very large gains. He then travelled in Germany, and after his return to Florence discharged several ambassadorial missions. At the death of his father he was possessed of a vast fortune and an extended experience, and inherited the leadership of the opposition to the then dominant party of the greater gilds headed by Rinaldo degli Albizzi, Palla Strozzi and Nicolò da Uzzano. Of gentle and kindly manners, generous in lending and even in giving money whenever he could gain popularity by that means, at critical moments he frequently came to the rescue of the government itself. He was very determined in turning his private liberalties to account for the increase of his political prestige, and showed no less acumen and still fewer scruples in making use of his political prestige for purposes of pecuniary profit. Indeed, whenever his own interests were at stake, he showed himself capable of positive villainy, although this was always tempered by calculation. Cosimo proved his skill in these knavish arts during the war between Florence and Lucca. He had joined the Albizzi in urging on this war, and many writers assert that he turned it to much pecuniary advantage by means of loans to the government and other banking operations. When, however, military affairs went badly, Cosimo joined the discontented populace in invectives against the war and the king that had conducted it. This gave him an enormous increase of popularity, but the hatred of the Albizzi and their friends augmented in equal degree, and a conflict became inevitable. The Albizzi, who were far more impetuous and impatient than Cosimo, were now bent upon revenge. In 1433 one of their friends, Bernardo Guadagni, was elected gonfalonier, and thereupon Cosimo dei Medici was called to the palace and summarily imprisoned in the tower. A general assembly of the people was convoked and a balta chosen, which changed the government and sent Cosimo into exile. Undoubtedly the Albizzi party would have preferred a heavier sentence, but they did not dare to attempt their enemy’s life, being well aware of the great number of his adherents. Cosimo had some apprehension that he might be poisoned in prison, but Federigo dei Malavolti, captain of the palace guard, showed him the utmost kindness and also soothed his fears, voluntarily shared his meals. On the 3rd of October the prisoner was sent to Padua, his allotted place of exile.

The Albizzi speedily saw that they had done either too much or too little. While seeking to keep the government entirely in their own hands, they beheld the continual growth of the Medici party. When it was necessary to make a campaign in Romagna against the mercenary captains commanding the forces of the duke of Milan, it was plainly seen that in banishing Cosimo the republic had lost the only citizen banker in a position to assist it with considerable loans. The Florentines were defeated by Piccinino in 1434, and this event greatly increased the public exasperation against the Albizzi. Meanwhile Cosimo, who at this time could be a private individual was entertained there like a prince. Then, being permitted to travel, he went to his residence to Venice, he entered on a course of lavish expenditure. He was overwhelmed with letters and appeals from Florence. Finally, on the 1st of September 1434, a sigurna was elected composed of his friends, and his recall was decreed. Rinaldo degli Albizzi determined to oppose it by force, and rushed to the Piazza with a band of armed men; but his attempt failed, and he left the country to return no more. The Medici were now reinstated in all their former dignities and honors, and Cosimo, on the evening of the 6th of September, rode past the deserted mansions of the Albizzi and re-entered his own dwelling after an exile of a year. For three centuries, dating from that moment, the whole history of Florence was connected with that of the house of Medici.

Cosimo’s first thought was to secure himself against all future risk of removal from Florence, and accordingly he drove the most powerful citizens into exile to all parts of Italy. Nor did he spare even his former political adversary, Palla Strozzi, although the latter had been favourable to him during the recent changes. His rigour in this particular case was universally censured, but Cosimo would tolerate no rivals in the city, and was resolved to abase the great families and establish his power by the support of the lower classes. He was accustomed to say that states could not be ruled by paternosters. Still, when cruelty seemed requisite, he always contrived that the chief odium of it should fall upon others. When Neri Capponi, the valiant soldier and able diplomatist, gained great public favour by his military prowess, and his influence was further increased by the friendship of Baldacchino d’Anghian, captain of the infantry, Cosimo determined to weaken his position by indirect means. Accordingly, when in 1441 a partisan of the Medici was elected gonfalonier, Baldacchino was instantly summoned to the palace, imprisoned, murdered, and his body hurled from the window. No one could actually fix this crime upon Cosimo, but the majority believed that he had thus contrived to rid himself of one enemy and cripple another without showing his hand. It was impossible for Cosimo openly to assume the position of tyrant of Florence, nor was it worth his while to become gonfalonier, since the term of office only lasted two months. It was necessary to discover some other way without resorting to violence; he accordingly employed what were then designated “civil methods.” He managed to attain his object by means of the balta. These magistracies, which were generally renewed every few years, served in the ballot for the names of the candidates from whom the signory and other chief magistrates were to be chosen. As soon as a balta favourable to Cosimo was formed, he was assured for five years of having the government in the hands of men devoted to his interests. He had comprehended that the art of politics depended rather upon individuals than institutions, and that he who ruled men could also dictate laws. His foreign policy was no less astute. His great wealth enabled him to supply money not only to private individuals, but even to foreign potentates. Philippe de Comines tells us that Cosimo frequently furnished Edward IV. of England with sums amounting to many hundred thousand florins. When Tommaso Parentucelli was still a cardinal, and in need of circumstances, Cosimo made him considerable loans. The name of his grace got on the cardinal’s accession to the tides Nicholas V. he was naturally very well disposed towards Cosimo, and employed the Medici bank in Rome in all the affairs of the curia. At the time when Francesco Sforza was striving for the lordship of Milan, Cosimo foresaw his approaching triumph, showed him great friendship, and aided him with large sums of money. Accordingly, when Sforza became lord of Milan, Cosimo’s power was doubled.

Without the title of prince, this merchant showed royal generosity in his expenditure for the promotion of letters and the fine arts. Besides his palace in the city, he constructed noble villas at Careggi, Fiesole and other places. He built the basilica of Fiesole, and that of St Lorenzo in Florence, and enlarged the church and monastery of St Mary of Pistoia. Even in distant Jerusalem he became his holiest house for the use of pilgrims. The artists of the day comprised men like Donatello, Brunelleschi, Ghiberti, Luca della Robbia, and many others, and Cosimo’s magnificent commissions not only developed their powers but stimulated other men of wealth to the patronage of art. Without being a scholar, Cosimo had a genuine taste for letters. He purchased many Greek and Latin manuscripts; he opened the first public library at St Mark’s at his own expense, and founded another in the abbey of Fiesole. The Greek refugees from Constantinople found a constant welcome in his palace. During the Council of Florence (1439-1442), Gemistus Pletho spoke to him with enthusiasm of the Platonic philosophy. Cosimo was so deeply attracted by the theme that he decided to have the young Marsilio Ficino trained in philosophy and Greek learning in order to make a Latin translation of the complete works of Plato. And thus...
version was produced that is still considered one of the best extant, and that Platonic academy was founded which led to such important results in the history of Italian philosophy and letters. On the 1st of August 1464 Cosimo breathed his last, at the age of seventy-five, while engaged in listening to one of Plato's dialogues.

The concluding years of his life had been years of little happiness for Florence. Being old and infirm, he had left the government to the management of his friends, among whom Luca Pitti was one of the most powerful, and they had ruled with disorder, corruption, and cruelty. The lordship of Florence accordingly did not pass without some difficulty and danger into the hands of Piero, surnamed the Gouty, Cosimo's only surviving legitimate son. Afflicted by gout, and so terribly crippled that he was often only able to use his tongue, the new ruler soon discovered that a plot was on foot to overthrow his power. However, showing far more courage than he was supposed to possess, he had himself borne on a litter from his villa to Florence, defeated his enemies' designs, and firmly re-established his authority. But his success may be mainly attributed to the enormous prestige bequeathed by Cosimo to his posterity. Piero died at the end of five years' reign, on the 3rd of December 1469, leaving two sons, Lorenzo (1449-1492) and Giuliano (1453-1478). The younger, the gentler and less ambitious of the pair, was quickly removed from the world. Lorenzo, on the contrary, at once seized the reins of state with a firm grasp, and was, chronologically, the second of the great men beset upon Italy by the house of Medici. In literary talent he was immensely superior to Cosimo, but greatly his inferior in the conduct of the commercial affairs of the house. In politics he had nobler conceptions and higher ambitions, but he was more easily carried away by his passions, less prudent in his revenge, and more disposed to tyranny. He had studied letters from his earliest years under the guidance of Ficino and other leading litterati of the day. At the age of eighteen he visited the different courts of Italy. At his father's death he was only twenty-one years old, but instantly showed his determination to govern Florence with greater despotism than his father or grandfather. He speedily resorted to the system of the balia, and was very dexterous in using the first to be chosen to suit his purpose. He then proceeded to humiliate the great families and exalt those of little account, and this was the policy he constantly pursued. His younger brother Giuliano, being of a mild and yielding disposition, had only a nominal share in the government.

Lorenzo's policy, although prosecuted with less caution, was still the old astute and fortunate policy initiated by Cosimo. But the grandsons bestowed no care upon his commercial interests, although squandering his fortune with far greater lavishness. Accordingly he was sometimes driven to help himself from the public purse without ever being able to assist it as Cosimo had done. All this excited blame and enmity against him, while his greed in the matter of the alum mines of Volterra, and the subsequent lack of that unhappy city, were crimes for which there was no excuse. Among his worst enemies were the Pazzi, and, as they formed a very powerful clan, he sought their ruin by competing with them even in business transactions. They were on the point of inheriting the large property of Giovanni Borromeo when Lorenzo hurriedly caused a law to be passed that altered the right of succession. The hatred of the Pazzi was thereby exasperated to fury. And in addition to these things there ensued a desperate quarrel with Pope Sixtus IV., a man of very impetuous temper, who, on endeavouring to erect a state on the frontiers of the Florentine republic for the benefit of his nephews, found a determined and successful opponent in Lorenzo. Consequently the Pazzi and Archbishop Salvati, another enemy of Lorenzo, aided by the nephews of the pontiff, who was himself acquainted with the whole matter, determined to put an end to the family. On the 26th of April 1478, while Giuliano and Lorenzo were attending high mass in the cathedral of Florence, the former was mortally stabbed by conspirators, but the latter was able to beat back his assailants and escape into the sacristy. His life preserved, and no longer having to share the government with a brother, Lorenzo profited by the opportunity to wreak cruel vengeance upon his foes. Several of the Pazzi and their followers were hanged from the palace windows; others were hacked to pieces, dragged through the streets, and cast into the Arno, while a great many more were condemned to death or sent into exile. Lorenzo seemed willing and able to become a tyrant. But he stopped short of this point. He knew the temper of the city, and had to look to fresh dangers threatening him from without. The pope had excommunicated him, put Florence under an interdict, and, being seconded by the Neapolitan king, made furious war against the republic. The Florentines began to tire of submitting to so many hardships in order to support the yoke of a fellow-citizen. Lorenzo's hold over Florence seemed endangered. But he rose superior to the difficulties by which he was encompassed. He boldly journeyed to Naples, to the court of King Ferdinand of Aragon, who was reputed to be as treacherous as he was cruel, and succeeded in obtaining from him an honourable peace, that soon led to a reconciliation with Sixtus. Thus at last Lorenzo found himself complete master of Florence. But, as the balia changed every five years, it was always requisite, in order to retain his supremacy, that he should be prepared to renew the usual manœuvre at the close of that term and have another elected equally favourable to his aims. This was often a difficult achievement, and Lorenzo showed much dexterity in overcoming all obstacles. In 1480 he compassed the institution of a new council of seventy, which was practically a permanent balia with extended powers, inasmuch as it no longer elected the chief magistrates, but had also the administration of numerous state affairs. This permanent council of devoted adherents once formed, his security was firmly established. By this means, the chroniclers tell us, 'liberty was buried,' but the chief affairs of the state were always conducted by intelligent and experienced men, who promoted the public prosperity. Florence was still called a republic; the old institutions were still preserved, if only in name. Lorenzo was absolute lord of all, and virtually a tyrant. His immorality was scandalous; he kept an army of spies; he frequently meddled in the citizens' most private affairs, and exalted men of the lowest condition to important offices of the state. Yet, as Guicciardini remarks, 'if Florence was to have a tyrant, she could never have found a better or more pleasant one.' In fact all industry, commerce and public works made enormous progress. The civil equality of modern times, which was quite unknown in the middle ages, was developed in Florence than in any other city of the world. Even the condition of the peasantry was far more prosperous than elsewhere. Lorenzo's authority was not confined to Tuscany, but was also very great throughout the whole of Italy. He was on the friendliest terms with Pope Innocent VIII., from whom he obtained the exaltation of his son Giovanni to the cardinalate at the age of fourteen. This boy-cardinal was afterwards Pope Leo X. From the moment of the decease of Sixtus IV., the union of Florence and Rome became the basis of Lorenzo's foreign policy. By its means he was able to prevent the hatreds and jealousies of the Sforzas of Milan and the Aragonese of Naples from bursting into the open conflict that long threatened, and after his death actually caused, the beginning of new and irreparable calamities. Hence Lorenzo was styled the needle of the Italian compass.

But the events we have narrated cannot suffice for the full comprehension of this complex character, unless we add the record of his deeds as a patron of letters and his achievements as a writer. His palace was the school and resort of illustrious men. Within its walls were trained the two young Medici afterwards known to the world as Leo X. and Clement VII. Ficino, Poliziano, Pico della Mirandola and all members of the Platonic academy were its constant habitués. It was here that Pulci gave readings of his Morgante, and Michelangelo essayed the first strokes of his chisel. Lorenzo's intellectual powers were of exceptional strength and versatility. He could speak with
equal fluency on painting, sculpture, music, philosophy and poetry. But his crowning superiority over every other Maecenas known to history lay in his active participation in the intellectual labours that he promoted. Indeed at certain moments he was positively the leading spirit among the litterati of his time. He was an elegant prose writer, and was likewise a poet of real originality. At that period Italians were forsaking erudition in order to forward the revival of the national literature by recurring to the primitive sources of the spoken tongue and popular verse. It is Lorenzo's lasting glory to have been the initiator of this movement. Without being—as some have maintained—a poet of genius, he was certainly a writer of much finish and eloquence, and one of the first to raise popular poetry to the dignity of art. In his Ambra, his Caccia del falcon and his Nencia da Barberino, he gives descriptions of nature and of the rural life that he loved, with the graphic power of an acute and tasteful observer, joined to an ease of style that occasionally sins by excess of homeliness. Both in his art and in his politics he leaned upon the people.

The more oppressive his government, the more did he seek in his verses to incite the public to festivities and lull it to slumber by sensual enjoyment. In his Balate, or songs for dancing, and more specifically for the revival of revelry, in order himself, Lorenzo displayed all the best qualities and worst defects of his muse. Marvelously and spontaneously elegant, very truthful and fresh in style, fertile in fancy and rich in colour, they are often of a most revolting indecency. And these compositions of one filling a princely station in the city were often sung by their author in the public streets, in the midst of the populace.

Lorenzo left three sons—Pietro (1472–1503), Giovanni (1475–1521) and Giuliano (1470–1516). He was succeeded by Pietro, whose rule lasted but for two years. During this brief term he performed no good deeds, and only displayed inordinate vanity and frivolity. His conduct greatly helped to foment the hatred between Lodovico Sforza and Ferdinand of Naples, which hastened the coming of the French under Charles VIII., and the renewal of foreign invasions. No sooner did the French approach the frontiers of Tuscany than Pietro, crazed with fear, hastened to meet them, and, basely yielding to every demand, accepted terms equally humiliating to himself and the state. But, returning to Florence, he found that the enraged citizens had already directed his head, in order to reach the throne, the scaffold, and was therefore compelled to escape to Venice. His various plots to reinstate himself in Florence were all unsuccessful. At last he went to the south of Italy with the French, was drowned at the passage of the Carigliano in 1503, and was buried in the cloister of Monte Cassino.

The ensuing period was adverse to the Medici, for a republican government was maintained in Florence from 1494 to 1512, and the city remained faithful to its alliance with the French, who were all-powerful in Italy. Cardinal Giovanni, the head of the family, resided in Rome, playing the patron to a circle of litterati, artists and friends, seeking to increase his popularity, and calmly waiting for better days. The battle of Ravenna wrought the downfall of the fortunes of France in Italy, and led to the rise of those of Spain, whose troops entered Florence to destroy the republic and reinstate the Medici. Pietro had now been dead for some time, leaving a young son, Lorenzo (1492–1510), who was afterwards duke of Urbino. The following year (1513) Cardinal Giovanni was elected pope, and assumed the name of Leo X., and was afterwards exiled to Rome, leaving his brother Giuliano with his nephew Lorenzo in Florence, and accompanied by his cousin Giulio, who was a natural son of the Giuliano murdered in the conspiracy of the Pazzi, and was soon destined to be a cardinal and ultimately a pope. Meanwhile his kinsmen in Florence continued to govern that city by means of a balia. And thus, being masters of the whole of central Italy, the Medici enjoyed great authority throughout the country and their ambition plumed itself for still higher flights. This was the moment when Niccolo Machiavelli, in his treatise The Prince, counselled them to accomplish the unity of Italy by arming the whole nation, and expelling its foreign invaders.

Leo X., who was only indirectly connected with the history of Florence, gave his name to the age in which he lived in consequence of his magnificent patronage of art and letters in Rome. But he was merely a clever amateur, and had not the literary gifts of his father Lorenzo. He surrounded himself with versifiers and inferior writers, who enlivened his board and accompanied him wherever he went. He liked to lead a gay and untroubled life, was fond of theatrical performances, satires and other intellectual diversions. His patronage of the fine arts, his genuine affection for Raphael, and the numerous works he caused to be executed by him and other artists, have served to confer an exaggerated glory on his name. He had not the remotest idea of the grave importance of the Reformation, which indeed he unconsciously promoted by his reckless and shameless sale of indulgences. The whole policy of Pope Leo X. consisted in oscillating between France and Spain, in always playing fast and loose, and deceiving both powers in turn. Yet the evil results of this contemptible policy never seemed to disturb his mind. He finally joined the side of the emperor Charles V., and in 1521, at the time of the defeat of the French by the Spanish troops on the field of Pavia, he and his cousin Adda, he ceased to breathe at his favourite villa of Magliana.

Giuliano dei Medici had died during Leo's reign, in 1516, without having ever done anything worthy of record. He was the husband of Philiberta of Savoy, was duke of Nemours, and left a natural son, Ippolito dei Medici (1511–1555), who afterwards became a cardinal. Lorenzo, being of more ambitious temper, was by no means content to remain at the head of the Florence government hampered by many restrictions imposed by republican institutions, and subject to the incessant control of the pope. In his eagerness to agrandize his kinsmen, the latter had further decided to give Lorenzo the duchy of Urbino, and formally invested him in its rights, after expelling on false pretences its legitimate lord, Francesco Maria della Rovere. This prince, however, soon returned to Urbino, where he was joyously welcomed by his subjects, and Lorenzo regained possession only by a war of several months, in which he was wounded. In 1519 he also died, worn out by disease and excess. By his marriage with Madeleine de la Tour d'Auvergne, he had one daughter, Catherine, and a son, Charles (1519–1589). He left in his will to Henry, duke of Orleans, afterwards king of France. She played a long and sinister part in the history of that country. Lorenzo also left a natural son named Alessandro, inheriting the frizzled hair and projecting lips of the negro or mulatto slave who had given him birth. His miserable death will be presently related. Thus the only three surviving representatives of the chief branch of the Medici, Cardinal Giulio, Ippolito and Alessandro were all of illegitimate birth, and left no legitimate heirs.

Cardinal Giulio, who had laboured successfully for the reinstatement of his family in Florence in 1512, had been long attached to the person of Leo X. as his trusted factotum and companion. He had been generally regarded as the mentor of the pope, who had no liking for hard work. But in fact, his frivolity notwithstanding, Leo X. always followed his own inclinations. He had much aptitude for command, and pursued his shuffling policy without any mental anxiety. Giulio, on the contrary, shrank from all responsibility, muddled his brains in weighing the reasons for and against every possible decision, and was therefore a better tool of government in others' hands than he was fit to govern on his own. When Giuliano, Lorenzo's only son, died, the pope appointed the cardinal to the government of Florence. In that post, restricted within the limits imposed by republican institutions, and acting under the continual direction of Rome, he performed his duties fairly well. He caressed the citizens with hopes of extended liberties, which, although never destined to be fulfilled, long served to keep men's minds in a pleasant flutter of expectation; and when the more impatient spirits attempted to raise a rebellion he speedily quenched it in blood.

When, after the death of Leo X. and the very brief pontificate
of Adrian VI, he was elected pope (1552) under the name of Clement VII, he entrusted the government of Florence to Cardinal Silvio Passerini conjointly with Alessandro and Ippolito, who were still too young to do much on their own account.

The pontificate of Leo X. had been a time of felicity to himself if of disaster to Italy and the Church. The reign of Clement, on the contrary, was fatal to himself as well. His policy, like that of Leo X., consisted in perpetual oscillation between France and Spain. By his endeavours to trick all the world, he frequently ended in being tricked himself. In 1525 he was the ally of the French, who then suffered a terrible defeat at Pavia, where their king Francis I. was taken prisoner. The armies of Charles V. triumphantly advanced, without Clement being able to oppose any effectual resistance. Both Rome and Florence were threatened with a fearful catastrophe.

Thus far we have had no occasion to speak of the younger branch of the Medici, descended from Lorenzo, brother to Cosimo the elder. Always in obscurity, and hitherto held in check by the elder line, it first entered the arena of history when the other was on the point of extinction. In fact the most valiant captain of the papal forces under Giovanni de' Medici, afterwards known by the name of Giovanni delle Bande Nere. His father was Giovanni, son of Pier Francesco, who was the son of Lorenzo, the brother of Cosimo de' Medici. History has little to tell of the elder Giovanni; but his wife Caterina Sforza, of whom he was the third husband, was a woman of more than masculine vigour. Giovanni de' Medici married her in 1497, but died in 1508, leaving her with one son who was christened Lodovico, but afterwards took his father's name of Giovanni (1498–1526). Trained to arms from his earliest years, this youth inherited all the energy of his mother, whose Sforza blood seemed to infuse new life into the younger branch of the Medici. Notwithstanding his extreme youth, he had already achieved the title of the best captain in Italy. He had always fought with immense dash and daring, and was devotedly loved and obeyed by his soldiery. He was the only leader who opposed a determined resistance to the imperial forces. He was seriously wounded at Pavia, but continued fighting on the French side. On his recovery he joined the army of the League, and was much enraged by finding that the duke of Urbino, commander of the Venetian and papal forces, would never decide on attacking. When the imperial troops were struggling through the marshes of Mantua, surrounded on every side, and without stores or ammunition, Giovanni could not resign himself to inactivity like his colleagues in command. He was ignorant that the imperialists had just received supplies and artillery from the duke of Ferrara, and therefore daringly attacked them with a small body of men without taking any precautions for defence. One of the first shots fired by the enemy injured him so fatally that he died a few days after. He was married to Maria Salviati, by whom he had one son, Cosimo (1519–1572), who became the first grand duke of Tuscany, and indeed the founder of the grand duchy and the new Medici dynasty.

Meanwhile the imperial army pursued its march upon Rome, captured the Eternal City after a few hours' combat, and cruelly sacked it during many days (1527). Thanks to its perpetual shuffling and excessive avarice, the pope found himself utterly forsaken, and was obliged to seek refuge in the castle of St. Angelo, whence he only effected his escape after some months. He then signed a treaty of alliance with the emperor (1529), who sent an army to besiege Florence and restore the Medici, whom the people had expelled in 1527 on the re-establishment of the republic. After an heroic defence, the city was forced to surrender (1530); and, although it was expressly stipulated that the ancient liberties of Florence should be respected, every one foresaw that the conditions would be violated. In fact, pope and emperor immediately began to dispute as to which should be the new lord of the city. Clement VII. had inherited the traditional family dislike for the younger branch of his kin, and so the choice lay between the two bastard Ippolito and Alessandro. The former being a cardinal, the latter was chosen. Alessandro, who already bore the title of duke of Città di Penna, came to Florence in 1531, and by imperial patent was nominated head of the republic. According to the terms of this patent, the former liberty enjoyed under the Medicean rule was to remain intact. But no previous ruler of the city had enjoyed hereditary power confirmed by imperial patent, and such power was incompatible with the existence of a republic. Moreover, Clement VII. showed dissatisfaction with the uncertainty of the power conferred upon his kinsman, and finally succeeded in obtaining additional privileges. On the 4th of April 1532 a parliament was convoked for the last time in Florence, and, as usual, approved every measure proposed for acceptance. Accordingly a new council was formed of two hundred citizens elected for life, forty-eight of which number were to constitute a senate. Alessandro, as duke of the republic, filled the post of gonfalonier, and carried on the government with the assistance of three senators, changed every three months, who took the place of the suppressed signory.

The duke's chief advisers, and the contrivers of all these arrangements were Baccio Valori, Francesco Vettori and above all Francesco Guicciardini—men, especially the latter two, of lofty political gifts and extensive influence. The mind and character of Duke Alessandro were as yet comparatively unknown. At first he seemed disposed to rule with justice and prudence. But encountering difficulties that he was unable to overcome, he began to neglect the business of the state, and acted as if the sole function of government consisted in lulling the people by festivities and corrupting it by the dissolute life of which he set the example. The question of the moment was the transformation of the old republican régime into a princedom; as an unavoidable result of this change it followed that Florence was no longer to be the ruling city to whose inhabitants alone belonged the monopoly of political office. When the leading Florentine families realized not only that the republic was destroyed, but that they were reduced to equality with those whom they had hitherto regarded as their inferiors and subjects, their rage was indescribable, and hardly a day passed without the departure of influential citizens who were resolved to achieve the overthrow of their new ruler. They found a leader in Cardinal Ippolito dei Medici, who was then in Rome, embittered by the preference given to Alessandro, and anxious to become his successor with the least possible delay. Under the pressure of terror the duke at once became a tyrant. He garrisoned the different cities, and began the erection in Florence of the Fortezza da Basso, built chiefly at the expense of Filippo Strozzi, who afterwards met his death within its walls.

In 1534 Clement VII. died, and the election fell on Paul III., from whom Cardinal Ippolito hoped to obtain assistance. Accordingly the principal Florentine exiles were dispatched to Charles V. with complaints of Alessandro's tyranny and his shameless violation of the terms upon which the city had surrendered. Cardinal Ippolito also represented his own willingness to carry on the government of Florence in a more equitable manner, and promised the emperor a large sum of money. Reply being delayed by the emperor's absence, he became so impatient that he set out to meet Charles in Tunis, but on the 10th of August 1535 died suddenly at Itri, poisoned by order of Alessandro. Such at least was the general belief, and it was confirmed by the same fate befalling other enemies of the duke about the same time. On the emperor's return from Africa, the exiles presented themselves to him in Naples, and the venerable patriot Jacopo Nardi pleaded their cause. Duke Alessandro, being cited to appear, came to Naples accompanied by Francesco Guicciardini, who by speaking in his defence rendered himself odious to all friends of liberty, and irretrievably tarnished his illustrious name. The cardinal being dead, it was hard to find a successor to Alessandro. On this account, and perhaps to some extent through the emperor's personal liking for the duke, the latter rose higher than before in the imperial favour, married Margaret of Austria, the natural daughter of Charles,
and returned to Florence with increased power. And now Alessandro indulged unchecked in the lowest excesses of tyranny, and although commonly a bridgefoot, grew to increased libertinism. His whole time was passed in vicious haunts and in scandalous adventures. In order to conceal the obscurity of his birth, he left his mother to starve, and it was even asserted that he finally got rid of her by poison.

His constant associate in this disgraceful routine was his distant kinsman Lorenzo, generally known as Lorenzino dei Medici. Of the younger branch of the Medici, the latter was second cousin of the Cosimo already mentioned as the son of Giovanni delle Bande Nere. He had much culture and literary talent, but led an irregular life, sometimes acting like a madman and sometimes like a villain. He was a writer of considerable elegance, the author of several plays, one of which, the Aridioso, was held to be among the best of his age, and he was a worshipper of antiquity. Notwithstanding these tastes, when in Rome he knocked off the heads of some of the finest statues of the age of Adrian, an act by which Clement VII. was so incensed that he threatened to have him hanged. Thereupon Lorenzino fled to Florence, where he became the friend of Duke Alessandro, and his partner in the most licentious excesses. They went together to houses of ill-fame, and violated private dwellings and convents. They often showed themselves in public mounted on the same horse. All Florence eyed them with disgust, but no one foresaw the tragedy that was soon to take place.

On the evening of the 5th of January 1537, after a day passed in the usual excesses, Lorenzino led the duke to his own lodging, and left him there, promising shortly to return with the wife of Leonardo Giniro. Alessandro, worn out by the exertions of the day, fell asleep on the couch while awaiting Lorenzino's return. Before long the latter came accompanied by a desperate known as the Scorzon-concello. In a fit of fury, he stabbed him in the chest with their first thrusts, the duke fainted at his life, and was only saved after a violent struggle. The murderers then lifted the body into a bed, hid it beneath the clothes, and, Lorenzino having attached a paper to it bearing the words vinct amor patriae, laudumque immensa cupido, they both fled to Venice. In that city Lorenzino was assassinated some ten years later, in 1548, at the age of thirty-two, by order of Alessandro's successor.

He wrote an Apologia, in which he defended himself with great skill and eloquence, saying that he had been urged to the deed solely by love of liberty. For this reason alone he had followed the example of Brutus and played the part of friend and courier. The tone of this Apologia is so straightforward, sometimes even so eloquent and lofty, that we should be tempted to give it credence were it possible to believe the assertions of one who not only by his crime but by the infamy of his previous and subsequent career completely gave the lie to his vaunted nobility of purpose. By Alessandro's death the elder branch of the Medici became extinct, and thus the appearance of the younger line was heralded by a bloody crime.

When the duke's absence from his own palace was discovered on the morning of the 6th of January he was at first supposed to have spent the night with one of his mistresses; but}{

\[ \text{keen-witted and aspiring, strong and handsome in person, heir to the enormous wealth of the Medici, and, by the terms of the imperial patent, was Alessandro's lawful successor. Charles V. approved the nomination of Cosimo, who without delay seized the reins of government with a firm grasp. Like Alessandro, he was named head of the republic; and Guicciardini and others who had worked hardest in his cause hoped to direct him and keep him under their control. But Cosimo soon proved that, his youth notwithstanding, he was resolved to rule unshackled by republican forms and unhindered by advisers disposed to act as mentors. The Florentines had now an absolute prince who was likewise a statesman of eminent ability.} \]

On learning the death of Alessandro and the election of Cosimo, the exiles appreciated the necessity for prompt action, as delay would be fatal to the overthrow of the Medicean rule. They had received money and promises from France; they were strengthened by the adhesion of Filippo Strozzi and Baccio Valori, who had both become hostile to the Medici through the infamous conduct and mad tyranny of Alessandro; and Strozzi brought them the help of his enormous fortune and the prowess of that very distinguished captain, his son Piero. The exiles assembled their forces at Mirandola. They had about four thousand infantry and three hundred horse; among them were members of all the principal Florentine families; and their leaders were Bernardo Salviati and Piero Strozzi. They marched rapidly, and entered Tuscany towards the end of July 1537. Cosimo on this occasion displayed signal capacity and presence of mind. Informed of the exiles' movements by his spies, he no sooner learned their approach than he ordered Alessandro Vitelli to collect the best German, Spanish and Italian infantry at his disposal, and advance against the enemy without delay. On the evening of the 31st of July Vitelli marched towards Prato with seven hundred picked infantry and a band of one hundred horse, and on the way fell in with other Spanish foot soldiers in the anticipated condition. At early dawn the following morning he made a sudden attack on the enemies' advance guard close to Montemurlo, an old fortress converted into a villa belonging to the Nerli. Having utterly routed them, he proceeded to storm Montemurlo, where Filippo Strozzi and a few of his young comrades had taken refuge. They made a desperate resistance for some hours, and then, overwhelmed by superior numbers, were obliged to yield themselves prisoners. The main body of the army was still at some distance, having been detained in the mountains by heavy rains and difficult passes, and, on learning the defeat at Montemurlo, its leader turned back by the way he had come. Alessandro Vitelli re-entered Florence with his victorious army and his fettered captives. Cosimo had achieved his first triumph.

All the prisoners, who were members of great families, were brought before Cosimo, and were received by him with courteous coldness. Soon, however, a scaffold was erected in the Piazza, and on four mornings in succession four of the prisoners were beheaded. Then the duke saw fit to stay the executions. Baccio Valori, however, and his son and nephew were beheaded on the 20th of August in the courtyard of the Bargello. Filippo Strozzi still survived, confined in the Fortezza da Basso, that had been built at his expense. His family was illustrious, he had numerous adherents, and he enjoyed the protection of the French king. Nevertheless Cosimo only awaited some plausible pretext to rid himself of this dreaded enemy. He brought him to trial and had him put to the question. But this cruelty led to nothing; for Strozzi denied every accusation and bore the torture with much fortitude. On the 18th of December he was found dead in his prison, with a blood-stained sword by his side, and a slip of paper bearing these words: \textit{exquiri alterius nostris ex ossibus ulor.} It was believed that, having renounced all hope of his life being spared, Strozzi had preferred suicide to death at the hands of the executioner. Some, however, thought that Cosimo had caused him to be murdered, and adopted this mode of concealing the crime. The young prince's cold-blooded massacre of his captives cast an enduring shadow upon his reign and dynasty. But it was henceforward plain to all that he was
a man of stern resolve, who went straight to his end without scruples or half-measures. Before long he was regarded by many as the incarnation of Machiavelli’s Prince, “insomuch as he joined daring to talent and prudence, was capable of great cruelty, and yet could practise mercy in due season.” Guicciardini, who still pretended to act as mentor, and who on account of his many services had a certain influence over him, was obliged to withdraw from public life and busy himself with writing his History at his villa of Arcetri. He died in this retreat in 1540, and it was immediately rumoured that the duke had caused him to be poisoned. This shows the estimation in which Cosimo was now held. He punished with death all who dared to resist his will. By 1540 sentence of death had been pronounced against four hundred and thirty contumacious fugitives, and during his reign one hundred and forty men and six women actually ascended the scaffold, without counting those who perished in foreign lands by the daggers of his assassins. He reduced the old republican institutions to empty forms, by making the magistrates mere creatures of his will. He issued the sternest edicts against the rebels, particularly by the law known as the “Polverina,” from the name of its proposer Jacopo Polverini. This law decreed not only the confiscation of the property of exiles, but likewise that of their heirs, even if personally acquired by the latter. Cosimo ruled like the independent sovereign of a great state, and always showed the capacity, firmness and courage demanded by that station. Only, his state being small and weak, he was forced to rely chiefly upon his personal talent and wealth. It was necessary for him to make heavy loans to the different European sovereigns, especially to Charles V., the most rapacious of them all, and to give enormous bribes to their ambassadors. Besides, he had to carry on wars for the extension of his dominions; and neither his inherited wealth nor the large sums gained by confiscating the estates of rebellious subjects sufficed for all this outlay. He was accordingly compelled to put the people with taxes, and thus begin at once to diminish its strength.

Cosimo bore a special grudge against the neighbouring republics of Siena and Lucca. Although the latter was small and weak, and the former garrisoned by Spaniards, yet the spectacle of free institutions at the frontiers of his own state served as a continual incitement to subjects disaffected to the new régime. In fact Francesco Burlamacchi, a zealous Lucchese patriot, had conceived the design of re-establishing republican government in all the cities of Tuscany. Cosimo, with the emperor’s help, succeeded in having him put to death. Lucca, however, was an insignificant state making no pretence of rivalry, whereas Siena was an old and formidable foe to Florence, and had always given protection to the Florentine exiles. It was now very reluctantly submitting to the presence of a Spanish garrison, and, being stimulated by promises of prompt and efficacious assistance from France. Cosimo in rebellion expelled the Spaniards in 1552. Cosimo instantly wrote to the emperor in terms that appealed to his pride, asked leave to attack Siena, and begged for troops to ensure the success of his enterprise. As no immediate answer arrived, he feigned to begin negotiations with Henry II. of France, and, by thus arousing the imperial jealousy, obtained a contingent of German and Spanish infantry. Siena was besieged for fifteen months, and its inhabitants, aided by the valor of Piero Strozzi, who fought under the French flag, made a most heroic resistance, even women and children helping on the walls. But fortune was against them. Piero Strozzi sustained several defeats, and finally the Sienese, having exhausted their ammunition and being decimated by famine and the sword, were obliged to capitulate on honourable terms that were shamelessly violated. By the varied disasters of the siege and the number of fugitives the population was reduced from forty to eight thousand inhabitants, and Cosimo, always eager to resist, withdrew to Montalcino. Cosimo now ruled the city and territory of Siena in the name of Charles V., who always refused him its absolute possession. After the emperor’s abdication, and the succession of Philip II. to the Spanish throne, Cosimo at last obtained Siena and Porto Ferrano by giving up his claim to a sum of 200,000 ducats that he was to have received from Charles V.

In 1550 Cosimo also captured Montalcino, and thus formed the grand-duchy of Tuscany, but he continued to govern the new state—i.e. Siena and its territories—separately from the old. His rule was intelligent, skilful and despotic; but his enormous expenses drove him to raise large sums of money by special contrivances unsuited to the country and the people. Hence, notwithstanding the genius of its founder, the grand-duchy held from the first the elements of its future decay. Cosimo preferred to confer office upon men of humble origin in order to have pliable tools, but he also liked to be surrounded by a courtly aristocracy on the Spanish and French pattern. As no Tuscan aristocracy any longer existed, he created new nobles, and tempted foreign ones to come by the concession of various feudal privileges; and, to turn this artificial aristocracy to some account, he created the knights order of St Stephen, charged with the defence of the coast against pirates, which in course of time won much honour by its prowess. He also established a small standing army for the protection of his frontiers; but he generally employed German and Spanish troops for his wars, and always had a foreign bodyguard. At the commencement of his reign he opposed the popes in order to maintain the independence of his own state; but later, to obtain help, he truckled to them in many ways, even to the extent of giving up to the Inquisition his own confidant, Piero Carneschi, who, being accused of heresy, was beheaded and burnt in 1567. In reward for these acts of submission, the popes showed him friendship, and Pius V. granted him the title of grand-duce, conferring the patent and crown upon him in Rome, although the emperor had always withheld his consent. The measure most injurious to Tuscany was the fiscal system of taxes, of which the sole aim was to extort the greatest possible amount of money. The consequent damage to industry, commerce and agriculture was immense, and, added to the devastations caused by the Sienese War, led to their utter ruin. Otherwise Cosimo did not neglect useful measures for the interior prosperity of his state. He was no Maecenas; nevertheless he restored the Pisan university, enlarged that of Siena, had the public records classified, and also executed public works like the Santa Trinità bridge. During the great inundations of 1557 he turned his whole energy to the relief of the sufferers.

Cosimo had espoused Eleonora of Toledo, daughter of the viceroy of Naples, by whom he had several children. Two died in 1562, and their mother soon followed them to the grave. It was said that one of these boys, Don Garcia, had murdered the other, and then been killed by the enraged father. Indeed, Cosimo was further accused of having put his own wife to death; but neither rumour had any foundation. He now showed signs of illness and failure of strength. He was not old, but worn by the cares of state and self-indulgence. Accordingly in 1564 he resigned the government to his eldest son, who was to act as his lieutenant, since he wished to have power to resume the sceptre on any emergency. In 1570, by the advice of Pope Pius V., he married Camilla Martelli, a young lady of whom he had been long enamoured. In 1574 he died, at the age of fifty-four years and ten months, after a reign of thirty-seven years, leaving three sons and one daughter besides natural children. These sons were Francesco, his successor, who was already at the head of the government, Cardinal Ferdinando, and Piero.

Francesco I., born in 1541, began to govern as his father’s lieutenant in 1564, and was married in 1565 to the archduchess Giovanna of Austria. On beginning to reign on his own account in 1574, he speedily manifested his real character. His training in the hands of a partisan father had made him suspicious, false and despotic. Holding every one aloof, he carried on the government with the assistance of a few devoted ministers. He compelled his step-mother to retire to a convent, and kept his brothers at a distance from Florence. He loved the privileges of power without its burdens. Cosimo had known how to maintain his independence, but Francesco cast
himself like a vassal at Austria's feet. He reapèd his reward by obtaining from Maximilian II. the title of grand-duke, for which Cosimo had never been able to win the imperial sanction, but he forfeited all independence. Towards Philip II. he showed even greater submissiveness, supplying him with large sums of money wrung from his overtaxed people. He held entirely aloof from France, in order not to awake the suspicions of his protectors. He traded on his own account, thus creating a monopoly that was ruinous to the country. He raised the tax on corn to so high a rate that few continued to find any profit in growing it, and thus the Maremme, already partly devastated during the war with Siena, were converted into a desert. Even industry declined under this system of government; and, although Francesco founded porcelain manufactories and pietre dura works, they did not rise to any prosperity until after his death. His love of science and letters was the only Medicean virtue that he possessed. He had an absolute passion for chemistry, and passed much of his time in his laboratory. Sometimes indeed he gave audience to his secretaries of state standing before a furnace, bellows in hand. He took some useful measures to convert a portion of the coast of a new city at Leghorn, which at that time had only a natural and ill-sheltered harbour. The improvement of Leghorn had been first projected by Cosimo I., and was carried on by all the succeeding Medici. Francesco was a slave to his passions, and was led by them to scandalous excesses and deeds of bloodshed. His example and neglect of the affairs of the state soon caused a vast increase of crime even among the people, and, during the first eighteen months of his reign, there occurred no fewer than one hundred and sixty-eight murders.

In default of public events, the historians of this period enliven upon private incidents, generally of a scandalous or sanguinary kind. In 1575 Orazio Pucci, wishing to avenge his father, whom Cosimo had hanged, determined to get up a conspiracy, but, soon recognizing how firmly the Medicean rule had taken root in the country, desisted from the attempt. But the grand-duke, on hearing of the already abandoned plot, immediately caused Pucci to be hanged from the same window of the Palazzo Vecchio, and even from the same iron stanchion, from which his father before him had hung. His companions, who had fled to France and England, were pursued and murdered by the ducal emissaries. Their possessions were confiscated, and the "Polverina" law applied, so that the conspirators' heirs were reduced to penury, and the grand-duke gained more than 300,000 ducats.

Next year Isabella dei Medici, Francesco's sister, was strangled in her nuptial bed by her husband, Paolo Giordano Orsini, whom she had betrayed. Piero dei Medici, Francesco's brother, murdered his wife Eleonora of Toledo from the same motive. Still louder scandal was caused by the ducal's own conduct. He was already a married man, when, passing one day through the Piazza of St Mark in Florence, he saw an exceedingly beautiful woman at the window of a mean dwelling, and at once conceived a passion for her. She was the famous Bianca Cappello, a Venetian of noble birth, who lived in Florence, and named Pietro Buonaventuri, to whom she was married at the time that she attracted the ducal's gaze. He made her acquaintance, and, in order to see her frequently, nominated her husband to a post at court. Upon this, Buonaventuri behaved with so much insolence, even to the nobility, that one evening he was found murdered in the street. Thus the grand-duke, who was thought to have sanctioned the crime, was able to indulge his passion unchecked. On the death of the grand-duchess in 1578 he was privately united to Bianca, and afterwards married her publicly. But she had no children, and this served to poison her happiness, since the next in succession was her bitter enemy, the cardinal Ferdinand. The latter came to Florence in 1587, and was ostentatiously welcomed by Bianca, who was most anxious to conciliate him. On the 18th of October of the same year the grand-duke died at his villa of Poggio a Caiano, of a fever caught on a shooting excursion in the Maremme, and the next day Bianca also expired, having ruined her health by drugs taken to cure her sterility. But rumour asserted that she had prepared a poisoned tart for the cardinal, and that, when suspiciously insisted on the grand-duke tasting it first, Bianca desperately swallowed a slice and followed her husband to the tomb.

Such was the life of Francesco dei Medici, and all that can be said in his praise is that he gave liberal encouragement to a few artists, including de Giovanni Bologna (q.v.). He was the founder of the Uffizi gallery, of the Medici theatre, and the villa of Pratolino; and during his reign the Dell'Cruscan academy was instituted.

Ferdinand I. was thirty-eight years of age when, in 1587, he succeeded his brother on the throne. A cardinal from the age of fourteen, he had never taken holy orders. He showed much tact and experience in the management of ecclesiastical affairs. He was the founder of the Villa Medici at Rome, and the purchaser of many priceless works of art, such as the Niobe group and many other statues afterwards transported by him to Florence. After his accession he retained the cardinal's purple until the time of his marriage. He was in all respects his brother's opposite. Affable in his manners and generous with his purse, he chose a crest typical of the proposed mildness of his rule—a swarm of bees with the motto Majestate tantiunt. He instantly pardoned all who had opposed him, and left his kinsmen at liberty to choose their own place of residence. Occasionally, for political reasons, he committed acts unworthy of his character; but he re-established the administration of justice, and sedulously attended to the business of the state and the welfare of his subjects. Accordingly Tuscany revived under his rule and regained the independence and political dignity that his brother had sacrificed to love of ease and personal indulgence. He favoured commerce, and effectually ensured the prosperity of Leghorn, by an edict enjoining toleration towards Jews and heretics, which led to the settlement of many foreigners in that city. He also improved the harbour and facilitated communication with Pisa by means of the Naviglio, a canal into which a portion of the water of the Arno was turned. He nevertheless retained the reprehensible custom of trading on his own account, keeping banks in many cities of Europe. He successfully accomplished the draining of the Val di Chiana, cultivated the plains of Pisa, Fucecchio and Val di Nievole, and executed other works of public utility at Siena and Pisa. But his best energies were devoted to the foreign policy by which he sought to emancipate himself from subjection to Spain. On the assassination (1589) of Henry III. of France Ferdinand supported the claims of the king of Navarre, undeterred by the opposition of Spain and the Catholic League, who were dismayed by the prospect of a Huguenot succeeding to the throne of France. He lent money to Henry IV., and strongly urged his conversion to Catholicism; he helped to persuade the pope to accept Henry's abjuration, and pursued this policy with marvellous persistence until his efforts were crowned with success. Henry IV. showed faint gratitude for the benefits conferred upon him, and paid no attention to the expostulations of the grand-duke, who attempted to slacken the relations with France, and showed that he could guard his independence by other alliances. He gave liberal assistance to Philip III. for the campaign in Algiers, and to the emperor for the war with the Turks. Hence he was compelled to burden his subjects with enormous taxes, forgetting that while guaranteeing the independence of Tuscany by his loans to foreign powers he was increasingly sapping the strength of future generations. He at last succeeded in obtaining the formal investiture of Siena, which Spain had always considered a fief of her own.

During this grand-duke's reign the Tuscan navy was notably increased, and did itself much honour on the Mediterranean. The war-galleys of the knights of St Stephen were despatched to the coast of Barbary to attack Bona, the headquarters of the corsairs, and they captured the town with much dash and bravery. In the following year (1608) the same galleys achieved their most brilliant victory in the archipelago over the stronger fleet of the Turks, by taking nine of their vessels, seven hundred prisoners, and jewels of the value of 2,000,000 ducats.
Ferdinand I.

Ferdinand I. died in 1609, leaving four sons, of whom the eldest, Cosimo II., succeeded to the throne at the age of nineteen.

Cosimo II.

He was at first assisted in the government by his mother and a council of regency. He had a good disposition, and the fortune to reign during a period when Europe was at peace and Tuscany blessed with abundant harvests. Of his rule there is little to relate. His chief care was given to the galleys of St Stephen, and he sent them to assist the Druses against the Porte. On one occasion he was involved in a quarrel with France.

Cosimo Concini, the Marshal d'Ancre, being assassinated in 1617, Louis XIII. claimed the right of transferring the property of the murdered man to De Luynes. Cosimo, refusing to recognize the confiscation decreed by the French tribunals, demanded that Concini's son should be allowed to inherit. Hence followed much ill-feeling and mutual reprisals between the two countries, finally brought to an end by the intervention of the duke of Lorraine.

Like his predecessors, Cosimo II. studied to promote the prosperity of Leghorn, and he deserves honour for abandoning all commerce on his own account. But it was no praiseworthy act to pass a law depriving women of almost all rights of inheritance. By this means many daughters of the nobility were driven into convents against their will. He gave scanty attention to the general affairs of the state. He was fond of luxury, spent freely on public festivities and detested trouble. Tuscany was apparently tranquil and prosperous; but the decay of which the seeds were sown under Cosimo I. and Ferdinand I. was rapidly spreading, and became before long patent to all and beyond all hope of remedy. The best deed done by Cosimo II. was the protection accorded by him to Galileo Galilei, who had removed to Padua, and there made some of his greatest discoveries. The grand duke recalled him to Florence in 1610, and nominated him court mathematician and philosopher. Cosimo died in February 1621. Feeling his end draw near, when he was only aged thirty and all his sons were still in their childhood, he hastened to arrange his family affairs. His mother, Cristina of Lorraine, his wife, Maddalena of Austria, were nominated regents and guardians to his eldest son Ferdinand II., a boy of ten, and a council of four appointed, whose functions were regulated by law. After Cosimo's death, the young Ferdin- dian was sent to Rome and Vienna to complete his education, and the government of Tuscany remained in the hands of two jealous and quarrelsome women. Thus the administration of justice and finance speedily went to ruin. Out of submissiveness to the pope, the regents did not dare to maintain their legitimate right to inherit the duchy of Urbino. They conferred exaggerated privileges on the new Tuscan nobility, which became increasingly insolent and worthless. They resumed the practice of trading on their own account, and, without reposing much benefit thereby, did the utmost damage to private enterprise.

In 1627 Ferdinand II., then aged seventeen, returned to Italy and assumed the reins of government; but, being of a very gentle disposition, he did not dare to assert his right to govern with any asseveration of will, and his brothers, and changed matters in such wise that each was almost independent of the other. He gained the love of his subjects by his great goodness; and, when Florence and Tuscany were ravaged by the plague in 1630, he showed admirable courage and carried out many useful measures. But he was totally incapable of energy as a statesman. When the pope made bitter complaints because the board of health had dared to subject certain monks and priests to the necessary quarantine, the grand-duke insisted on his officers asking pardon on their knees for having done their duty.

On the death in 1637 of the last duke of Urbino, the pope was allowed to seize the duchy without the slightest opposition on the part of Tuscany. As a natural consequence the pretensions of the Roman curia became increasingly exorbitant; ecclesiastics usurped the functions of the state; and the ancient laws of the republic, together with the regulations decreed by Cosimo I. as a check upon similar abuses, were allowed to become obsolete. On the extinction of the line of the Gonzagas at Mantua in 1627, war broke out between France on the one side and Spain, Germany and Savoy on the other. The grand duke, uncertain of his policy, trimmed his sails according to events. Fortunately peace was re-established in 1631. Mantua and Monferrato fell to the duke of Nevers, as France had always desired. But Europe was again in arms for the Thirty Years' War, and Italy was not at peace. Urban VIII. wished to aggrandize his nephews, the Barberini, by wrestling Castro and Ronciglione from Odoardo Farnese, duke of Parma and brother-in-law to Ferdinand. Farnese marched his army through Tuscany into the territories of the pope, who was greatly alarmed by the attack. The grand-duke was drawn into the war to defend his own state and his kinsman. His military operations, however, were of the feeblest and often the most laughable character. At last, by means of the French intervention, peace was made in 1644. But, although the pope was forced to yield, he resigned none of his ecclesiastical pretensions in Tuscany. It was during Ferdinand's reign that the septuagenarian Galileo was obliged to appear before the Inquisition in Rome, which treated him with infamous cruelty. On the death of this great and unfortunate man, the grand-duke wished to erect a monument to him, but was withheld by fear of the opposition of the clergy. The dynasty as well as the country now seemed on the brink of decay. Two of the grand-duke's brothers had already died childless, and Ippolito, the sole survivor, was a cardinal. The only remaining heir was his son Cosimo, born in 1642.

Like nearly all his predecessors, Ferdinand II. gave liberal patronage to science and letters, greatly aided therein by his brother Leopold, who had been trained by Galileo Galilei, and who joined with men of learning in founding the celebrated academy Del Cimento, of which he was named president. This academy took for its motto the words Provando e riprovando, and followed the experimental method of Galileo. Formed in 1657, it was dissolved in 1657 in consequence of the jealousies and dissensions of its members, but during its brief existence won renown by the number and importance of its works.

Cosimo III. succeeded his father in 1670. He was weak, vain, bigoted and hypocritical. In 1667 he had espoused Louise of Orléans, niece of Louis XIV., who, being enamoured of duke Charles of Lorraine, was very reluctant to come to Italy, and speedily detested both her husband and his country, of which she refused to learn the language. She had two sons and one daughter, but after the birth of her third child, Giovanni Gastone, her hatred for her husband increased almost to madness. She first withdrew to Poggio a Caiano, and, being unable to get her marriage annulled, returned to France, where, although supposed to live in conventual seclusion, she passed the greater part of her time as a welcome visitor at court. Even her testamentary dispositions attested the violence of her dislike to her husband.

Cosimo's hypocritical zeal for religion compelled his subjects to multiply services and processions that greatly infringed upon their working hours. He wasted enormous sums in pensioning his relatives, and his first act on coming to the throne was giving rich endowments to sanctuaries. Meanwhile funds were devoted for the payment of government clerks and soldiers. His court was composed of bigots and parasites; he ransacked the world for dainties for his table, adorned his palace with costly foreign hangings, had foreign servants, and filled his gardens with exotic plants. He purchased from the emperor the title of "Highness" in order to be the equal of the duke of Savoy. He remained neutral during the Franco-Spanish War, and submitted to every humiliation and requisition exacted by the emperor. He had vague notions of promoting agriculture, but accomplished no results. At one time he caused eight hundred families to be brought over from the Morea for the cultivation of the Maremme, where all of them died of fever. But when, after the revocation of the Edict of Nantes, French Huguenots offered to apply their labour and capital to the same purpose, the grand duke's religious scruples refused them refuge. So ruin fell upon Tuscany. Crime and misery increased, and the poor, who only asked for work, were given alms and sent oftener to church. This period
witnessed the rise of many charitable institutions of a religious character under the patronage of the grand-duke, as for instance the congregation of San Giovanni Battista. But these could not remedy the general decay.

Cosimo’s dominant anxiety regarded the succession to the throne. His eldest son Ferdinando died childless in 1713. The pleasure-loving Giovan Gastone was married to Anna Maria of Saxe-Lauenburg, widow of a German prince, a wealthy, coarse woman wholly immersed in domestic occupations. After living with her for some time in a Bohemian village, Giovan Gastone yielded to his dislike to his wife and her country, withdrew to France, and ruined his health by his excesses. After a brief return to Bohemia he finally separated from his wife, by whom he had no family. Thus the dynasty was doomed to extinction.

thought on ascending it was to regain strength enough to pass the remainder of his days in enjoyment. He dismissed the spies, parasites and bigots that had formed his father’s court, abolished the pensions given to converts, suppressed seve. al taxes, and prohibited the organized espionage established in the family circle. He wished to live and let live, and liked the people to be amused. Everything in fact bore a freer and gayer aspect under his reign, and the Tuscans seemed to feel renewed attachment for the dynasty as the moment of its extinction drew near. But the grand-duke was too feeble and incapable to accomplish any real improvement. Surrounded by gay and dissipated young men, he entrusted all the cares of government to a certain Giuliano Dami, who drove a profitable trade by the sale of offices and privileges. In this way all things were in the hands of corrupt individuals; while the grand-duke, compelled to pass the greater part of his time in bed, vainly sought diversion in the company of buffoons, and was only tormented by perceiving that all the world disposed of his throne without even asking his advice. And when, after prolonged opposition, he had resigned himself to accept Don Carlos as his successor, the latter led a Spanish army to the conquest of Naples, an event afterwards leading to the peace of 1735, by which the Tuscan succession was transferred to Francesco II, duke of Lorraine, and husband of Maria Theresa. Giovan Gastone was finally obliged to submit even to this. Spain withdrew her garrisons from Tuscany, and Austrian soldiers took their place and swore fealty to the grand-duke on the 5th of February 1737. He expired on the 9th of July of the same year. Such was the end of the younger branch of the Medici, which had found Tuscany a prosperous country, where art, letters, commerce, industry and agriculture flourished.

MEDICI, GIACOMO (1817–1882), Italian patriot and soldier, was born at Milan in January 1817. Exiled in 1836, he fought in Spain against the Carlists between 1836 and 1840, and in 1841 joined Garibaldi at Montevideo. Returning to Italy with Garibaldi in 1848, he raised a company of volunteers to fight against Austria, and commanded the volunteer vanguard in Lombardy, proceeding thence to Rome, where he gained distinction by defending the "Vascoello," a position near the Porta San Pancrazio, against the French. During the siege of Rome he himself was wounded. In the war of 1859 he commanded a volunteer regiment, and was sent by Cavour into Tirol. In 1860 he tried in vain to dissuade Garibaldi from the Marsala expedition, but, after his chief's departure, he sailed for Sicily with the second expedition, taking part in the whole campaign, during which he forced Messina to capitulate after an eight days' siege. Joining the regular army, he was appointed military commandant of Palermo, in which capacity he facilitated the abortive campaign of Garibaldi in 1862. In 1866 he commanded the division which invaded Tirol, but the effect of his victories was neutralized by the conclusion of peace. Returning to Palermo he did great work in reorganizing the city. He became a senator in 1879, and marquis of the "Vascoello" and first aide-de-camp to the king in 1876. He died on the 9th of March 1882.

MEDICINE.—The science of medicine, as we understand it, has for its province the treatment of disease. The word "medicine" (Lat. medicina; sc. ars, art of healing, from mederi, to heal) may be used very widely, to include Pathology (q.v.), the theory of the causation of disease, or, very narrowly, to mean only the drug or form of remedy prescribed by the physician—this being more properly the subject of Therapeutics (q.v.) and Pharmacology (q.v.). But it is necessary in practice, for historical comprehensiveness, to keep the wider meaning in view.

Disease (see Pathology) is the correlative of health, and the word is not capable of a more penetrating definition. From the time of Galen, however, it has been usual to speak of the life of the body either as proceeding in accordance with nature (καρδ φύσι, secundum naturam) or as overstepping the bounds of nature (καρδ ἀρχαιομένη, præposterously). To base the claim to be a deflexion from the line of health, the first requisite of medicine is an extensive and intimate acquaintance with the norm of the body. The structure and functions of the body form the subject of Anatomy (q.v.) and Physiology (q.v.).

The medical art (ars medendi) divides itself into departments and subdepartments. The most fundamental division is into internal and external medicine, or into medicine proper and surgery (q.v.). The treatment of wounds, injuries and deformities, with operative interference in general, is the special department of surgical practice (the corresponding parts of pathology, including inflammation, repair, and removable tumours, are sometimes grouped together as surgical pathology); and where the work of the profession is highly subdivided, surgery becomes the exclusive province of the surgeon, while internal medicine remains to the physician. A third great department of practice is formed by obstetric medicine or midwifery (see Instrumentation and obstetrics, q.v.), and dental surgery is given up as a distinct branch of the profession.

A state of war, actual or contingent, gives occasion to special developments of medical and surgical practice (military hygiene and military surgery). Wounds caused by projectiles, sabres, &c., are the special subject of naval and military surgery; while under the head of military hygiene we may include the general subject of ambulances, the sanitary arrangements of camps, and the various forms of epidemic camp sickness.

The administration of the civil and criminal law involves frequent relations with medicine, and the professional subjects most likely to arise in that connexion, together with a summary of causes célèbres, are formed into the department of Medical Jurisprudence (q.v.).

In preserving the public health, the medical profession is again brought into direct relation with the state, through the public medical officers.

HISTORY OF MEDICINE

Medicine as Portrayed in the Homeric Poems.—In the state of society pictured by Homer it is clear that medicine has already had a history. We find a distinct and organized profession; we find a system of treatment, especially in regard to injuries, which it must have been the work of long experience to frame; we meet with a nomenclature of parts of the body substantially the same (according to Daremberg) as that employed long afterwards in the writings of Hippocrates; in short, we find a science and an organization which, however imperfect as compared with those of later times, are yet very far from being in their beginning. The Homeric heroes themselves are represented as having considerable skill in surgery, and as able to attend to ordinary wounds and injuries, but there is also a professional class, represented by Machaon and Podalirius, the sons of Asclepius, who are treated with great respect. It would appear, too, from the Aethiopis of Archilochus (quoted by Welcker and Häser) that the duties of these two were not precisely the same. Machaon's task was more especially to heal injuries, while Podalirius had received from his father the gift of recognizing what was not visible to the eye, and tending what could not be healed. In other words, a rough indication is seen of the separation of medicine and surgery. Asclepius appears in Homer as a Thessalian king, not as a god, though in later times divine honours were paid to him. There is no sign in the Homeric poems of the subordination of medicine to religion which is seen in ancient Egypt and India, nor are priests charged, as they were in those countries, with medical functions—all circumstances which throw grave doubts on the commonly received opinion that medicine derived its origin in all countries from religious observances.

Although the actual organization of medicine among the Homeric Greeks was thus quite distinct from religion, the worship of Asclepius (or Aesculapius) as the god of healing demands some notice. This cult spread very widely among the Greeks; it had great civil importance, and lasted even into Christian times; but there is no reason to think that it was connected with the origin of the science or profession of medicine. Sick persons repaired, or were conveyed, to the temples of Asclepius in order to be healed, just as in modern times relief is sought by a devotional pilgrimage from the waters of some sacred spring, and then as now the healing influence was sometimes sought by deputy. The sick person, or his representative, after ablation, prayer and sacrifice, was made to sleep on the hide of the sacrificed animal, or at the feet of the statue; he then received the appropriate remedy, (ψυκτικός) the appropriate remedy was indicated by a dream. Moral or dietetic remedies were more often prescribed than drugs. The record of the cure was inscribed on the columns or walls of the temple; while it has been produced in the literature in the form of gymnasia, or "recording cases," and that the physicians of the Hippocratic school thus learnt to accumulate clinical experience. But the priests of Asclepius were not physicians. Although the latter were often called Asclepiads, this was in the first place to indicate their real or supposed descent from Asclepius, and in the second place as a complimentary title. No medical writing of antiquity speaks of the worship of Asclepius in such a way as to
Development of Medicine in Greece.—It is only from non-medical writers that anything is known of the development of medicine in Greece before the age of Hippocrates. The elaborate collections made by Daremberg of medical notices in the poets and historians illustrate the relations of the profession to society, but do little to prepare us for the Hippocratic period. Nor is much importance to be attached to the influence of the philo-
sophical sects on medicine except as regards the school of
Pythagoras. That philosopher and several of his successors
were physicians, but we do not know in what relation they stood
to later medical schools. We must therefore hasten onward to
the age of Pericles, in which Hippocrates, already called "the
Great," was in medicine as complete a representative of the
highest efforts of the Greek intellect as were his contemporaries
the great philosophers, orators and tragedians. The medical
art as we now practise it, the character of the physician as we
now understand it, both date for us from Hippocrates. The
justification of this statement is found in the literary collection
of writings known by his name. Of these certainly many are
false and spurious, and the history of Hippocrates contains
works almost as certainly so ascribed; others again are clearly
works of his school, whether from his hand or not. But which
are to be regarded as the "genuine works" is still uncertain,
and authorities are conflicting. There are clearly two schools
represented in the collection—that of Cnidus in a small propor-
tion, and that of Cos in far the larger number of the works.
The latter was that to which Hippocrates belonged, and he
gave instruction; and accordingly it may be taken that works
of this school, when not obviously of a different date, are
Hippocratic in doctrine if not in actual authorship.
Hippocratic Medicine.—The first grand characteristic of
Hippocratic medicine is the high conception and duties of the
physician, shown in the celebrated "Oath of Hippocrates" and
elsewhere—equally free from the mysticism of a priesthood
and the vulgar pretensions of a mercenary craft. So matured a
professional sentiment may perhaps have been more the growth of
time and collection than the work of a man of genius, but certainly
corresponds with the character universally attributed to
Hippocrates himself. The second great quality is the singular artistic skill and
balance with which the Hippocratic physician used such materials
and tools as he possessed. Here we recognize the true Greek
expertise. But though the Hippocratic physician was not always
a genius, the cardinal virtue of Hippocratic medicine—the clear recognition
of disease as being equally with life a process governed by what we
should now call natural laws, which could be known by observation,
and which, if properly interpreted, would lead to adequate
recovery, by following which alone could the physician succeed.
In the fourth place, these views of the "natural history of disease"
(in modern language) led to habits of minute observation and
accurate interpretation of symptoms, in which the Hippocratic
method was unrivalled in antiquity, and has been the model for all succeeding
generations, so that even in these days, with our enormous advances in
knowledge, the true method of clinical medicine may be said to be the
method of Hippocrates. The actual science of the Hippocratic school was of course
limited. In anatomy and physiology little advance had been made, and so of pathology in the sense of an explanation of morbid processes
or disturbance of natural health which would be of very little value. The
most valuable intellectual possession was a large mass of clinical
observations in individual cases and epidemics of disease. Whether
these observations were systematic or individual, and how they were
recorded, is a point of which we are quite ignorant, as the theory
that the votive tablets in the temples supplied such materials must be
abandoned.

Though the Hippocratic medicine was so largely founded on observation, it would be an error to suppose that dogma or theory had
any place in the method of Hippocrates. In medical science, which has never since ceased to influence medical thought and practice.
According to this celebrated theory, the body contains four humours—blood, phlegm, yellow bile and black bile, a right proportion
and mixture of which constitutes health; improper proportions or irregular distribution, disease. It is doubtful whether the
system of which this theory is fully expounded (Ευξαλίαν ἄνθρωπον)
was actually the Hippocratic; but it was regarded as
a Hippocratic system, and, when taken up and expanded by Galen,
its terms not only became the common property of the profession,
Alexander School of Medicine.—The dispersion of Greek science and intellectual activity through the world by the conquests of Alexander and his successors led to the formation of more than one learned centre, in which medicine among other sciences was represented. Pergamum was early distinguished for its medical school; but in this as in other respects its reputation was ultimately effaced by the more brilliant fame of Alexandria. It is here that the real continuation and development of Hippocratic medicine can be traced.

In one department the Alexandrian school rapidly surpassed its Greek original—namely, in the study of anatomy. The dissection of the human body, of which some doubtful traces or hints only are found in Greek times, was assiduously carried out, being favored or even suggested perhaps by the Egyptian custom of disembowelling and embalming the bodies of the dead. There is no doubt that the organs were also examined by opening the bodies of living persons—carnivals condemned to death being given over to the anatomists for this purpose.

Two eminent names stand in the first rank as leaders of the two earliest schools of medicine which arose in Alexandria, Herophilus and Erasistratus.

Herophilus (335–280 B.C.) was a Greek of Chalcedon, a pupil of the school of Epimenides, and worked under the direction of his master, who was deceased. Herophilus devoted himself mainly to the study of the nervous system, and his profound researches in anatomy (see i. 802), and in the knowledge and practice of medicine he appears to have been equally renowned. He preserved himself a close adherent of Hippocrates, and especially of his standpoint in the use of drugs and of bleeding. The reputation of Herophilus is attested by the fact that four considerable physicians wrote works about him and his writings, and he is further spoken of with the highest respect by Galen and Celsus. By the general voice of the medical world of antiquity he was placed second only to Hippocrates.

Erasistratus (d. 280 B.C.) was the contemporary and rival of Herophilus. Little is known of his life, except that he spent some time in Egypt. It is said that he was a pupil of Herophilus at Alexandria, and that he cultivated anatomy late in life, after he had taken up his abode in the latter city. His numerous works are also almost entirely lost, fragments only being preserved by Galen and others. Erasistratus, instead of following Hippocrates as Herophilus did, depreciated him, and seems to have been rather aggressive and independent in his views. He appears to have leaned to mechanical explanations of the symptoms of disease, as was especially the case with inflammation, of which he gave the first rational, though necessarily inadequate, theory.

The two schools composed of the followers of Herophilus and Erasistratus respectively long divided between them the medical world. Both schools have the same points, but both sects have been lost in the theoretical subtleties, and to have maintained too high a degree of literary cultivation. The school of Erasistratus was least distinguished in anatomy than that of Herophilus, but paid more attention to the special symptoms of diseases, and employed a great variety of drugs. Erasistratus, from the writings of Celsus, Caelius Aurelianus, very considerable. Asclepiades had many pupils who adhered more or less closely to his doctrines, but it was especially one of them, Themison, who gave permanence to his name. Asclepiades was not satisfied with some of the Hippocratic modifications, a new system of medical doctrine, and founded on this basis a school which lasted for some centuries in successful rivalry with the Hippocratic tradition, which, as we have seen, was up to that time the prevailing influence in medicine.

This system as such was adherents as the methodists or methodists. Its main principles were that it was useless to consider the causes of a disease, or even the organ affected by the disease, and that it was sufficient to know what was common to all cases of a certain disease. Among such was a certain amount of morbid alteration in the organ, and a certain peculiar discharges of the water—in short, to a modified athletic training. He rejected the vis medicatrix naturae, pointing out that nature in many cases not only did not help but marred the cure. His knowledge of disease was derived from experiment, and he considered that the symptoms of disease were mere indications of the constitution of the body, and that they could not be altered by any treatment. He was of the opinion that the Hippocratic school, but to correcting the morbidity common condition of “community,” relaxing the body if it was constricted, causing less than in its native Alexandria, and appears to be recognizable even up to the beginning of the middle ages.

If we look at the work of the Alexandrian schools in medicine as a whole, we must admit that the progress made was great and permanent. The greatest service rendered to medicine was undoubtedly the systematic study of anatomy. It is clear that the knowledge of function (physiology) did not by any means keep pace with the knowledge of structure, and this was probably the reason why the important sect of the empirics were able entirely to dispense with anatomical knowledge. The doctrines of Hippocrates, though lightly thought of by the Erasistrateans, still were no doubt very widely accepted, but the practice of the Hippocratic school had been greatly improved in almost every department—surgery and obstetrics being probably those in which the Alexandrian practitioners could compare more favorably with these of modern times. We have now to trace the fortunes of this body of medical doctrine and practice when transplanted to Rome, and ultimately to the whole Roman world.

Roman Medicine.—The Romans cannot be said to have at any time originated or possessed an independent school of medicine. They borrowed from the early times a very complicated system of superstitious medicine and religion, related to disease, and the cure of disease, borrowed from the Etruscans; and, though the saying of Pliny that the Roman people got on for six hundred years without doctors was doubtless an exaggeration, and not, literally speaking, exact, it must be accepted for the broad truth which it contains. When a medical profession appears, it is, so far as we are able to trace it, as an importation from Greece.

The first Greek physician whose name is preserved as having migrated to Rome was Archagathus, who came from the Peloponnesus in 218 B.C.; but there were probably others before him. We know of two ancient physicians who flourished in Rome, but it is uncertain who were the first physicians. In the first place, the account given by Pausanias that physicians who sought their fortunes in Rome must have been very large. The better words of M. Porcius Cato, who disliked them as he did other representatives of Greek culture, are evidence of this. The most eminent of these earlier Greek physicians at Rome was Asclepiades, the friend of Cicero (born 124 B.C. at Prusa in Bithynia). He came to Rome as a young man, and soon became distinguished both for his medical skill and his oratorical power. He introduced a system which, so far as we know, was his own, though founded upon the Epicurean philosophical creed; on the practical side it conformed pretty closely to the Stoic rule of life, thus adapting itself to the teachings of Hippocrates. The most eminent of the later Greek physicians at Rome was Celsus, and Caelius Aurelianus, very considerable. Asclepiades had many pupils who adhered more or less closely to his doctrines, but it was especially one of them, Themison, who gave permanence to his name. Asclepiades was not satisfied with some of the Hippocratic modifications, a new system of medical doctrine, and founded on this basis a school which lasted for some centuries in successful rivalry with the Hippocratic tradition, which, as we have seen, was up to that time the prevailing influence in medicine.

This system as such was adherents as the methodists or methodists. Its main principles were that it was useless to consider the causes of a disease, or even the organ affected by the disease, and that it was sufficient to know what was common to all cases of a certain disease. Among such was a certain amount of morbid alteration in the organ, and a certain peculiar discharges of the water—in short, to a modified athletic training. He rejected the vis medicatrix naturae, pointing out that nature in many cases not only did not help but marred the cure. His knowledge of disease was derived from experiment, and he considered that the symptoms of disease were mere indications of the constitution of the body, and that they could not be altered by any treatment. He was of the opinion that the Hippocratic school, but to correcting the morbidity common condition of “community,” relaxing the body if it was constricted, causing...
contraction if it was too lax, and in the "mixed state," acting according to the predominant condition. This simple rule of treatment was the system or "method" from which the school took its name.

The methodists agreed with the empirics in one point in their contention with the rationalists: they were not strict rationalists, even though with a dogma different from that of the Hippocratic school. Besides Themison, its systematic founder, the school boasted many physicians eminent in their day, among whom Theossalus of Tralles, a half-educated man of the half-educated, was the most popular. He reversed the Hippocratic maxim "art is long," promising his scholars to teach them the whole of medicine in six months, and had inscribed upon his tomb inscription, as being superior to all living and having preceded perfection.

In the 2nd century a much greater name appears among the methodists, that of Soranus of Ephesus, a physician mentioned with praise even by Tertullian and Augustine, who practised at Rome in the reign of Hadrian. He is known as a writer, for his works are still extant in the Greek original, on the diseases of women, and also by the Latin work of Caecilius Aurelianus, three centuries later, on acute and chronic diseases, which is based upon, if not, as some think, an actual translation, of the chief work of Soranus, and which is the principal source of our knowledge of the methodic school. The work on diseases of women is the only complete work on that subject which has come down to us from antiquity, and shows the fullness of practical knowledge in relation to its subject. It is notable that an important instrument of research, the spectrum, which has been reinvented in modern times, was used by Soranus; and the number of studies, following great medical perception, have been found among the ruins of the Roman empire. The work on acute and chronic diseases is also full of practical knowledge, but penetrated with the theories of the methodists.

The 2nd century, and the following centuries, saw some centuries, and influenced the revival of medical science in the middle ages, though overshadowed by the greater reputation of Galen. It was the first definite product of Greek medicine on Roman soil, but was destined to be followed by others, which kept up a more or less successful rivalry with it, and with the Hippocratic tradition.

The so-called pneumatic school was founded by Aethenaeus, in the 1st century after Christ. According to its doctrines the normal as well as diseased actions of the body were to be referred to the operation of the pneuma or universal soul. This doctrine, crudely transferred from philosophical speculation, was intended to reconcile the humoral (or Hippocratic) and solidist (or methodist) schools; but the methodists seem to have claimed Aethenaeus as one of themselves.

The conflicts of the opposing schools, and the obvious deficiencies of each, led many physicians to try and combine the valuable parts of each system, and to call themselves eclectic. Among these was found many of the most eminent physicians of Graeco-Roman times. It may be sufficient to name Rufus or Ephesus (2nd century a.d.), and Archigenes (F. A.D. 90), who is mentioned by Juvenal.

Although no system or important doctrine of medicine was originated by the Roman intellect, and though the practice of the art was probably almost entirely in the hands of the Greeks, the most complete record of the medical thought and activity in Roman times is due to a Latin pen, and to one who was, in all probability, not a physician.

A. Cornelius Celsus, a Roman patrician, who lived probably in the 1st century, appears to have studied medicine as a branch of general knowledge. Whether he was a practising physician or not has been a matter of controversy. The conclusion supported by most evidence seems to be that he practised on his friends and dependants, but not as a remunerative profession. His well-known work, De medicina, was one of a series of treatises intended to embrace all knowledge proper for a man of the world. It was not meant for the physicians, and was certainly little read by them, as Celsus is quoted by no medical writer, and when referred to by Pliny, is spoken of as an author not a physician. Daremberg, with other scholars, has traced a large number of passages of the Latin text to the Greek originals from which they were translated. In the description of surgical operations the vagueness of the language seems sometimes to show that the author had not performed such himself; but in other parts, and especially in his historical introduction, he speaks with more confidence; and everywhere he compares and criticizes with learning and judgment. The whole body of medical literature belonging to the Hippocratic and Alexandrian times is ably summarized, and a knowledge of the state of medical science up to and during the times of the author is thus conveyed to us which can be obtained from no other source.

The work of Celsus is thus for us only second in importance to the Hippocratic writings and the works of Galen; but it is valuable rather as a part of the history of medicine than as the subject of that history. It forms no link in the general chain of medical tradition, for the simple reason that the influence of Celsus (putting aside a few scanty allusions in medieval times) commenced in the 1st century, when his works were first discovered in manuscript or committed to the press. Since then, however, he has been almost up to our own times the most popular and widely read of all medical classics, partly for the qualities already indicated, partly because he was one of the few of those classics accessible to readers of Latin, and partly also because of the purity and classical perfection of his language.

Of Pliny, another encyclopaedic writer, a few words must be said, though he was not a physician. In his Natural History we find as complete a summary of the popular medicine of his time as which seems in the end to have secured his popularity and established his pre-eminence in the medical world.

We now come to the writer who, above all others, gathered up into himself the divergent and scattered threads of ancient medicine, and out of whom again the greater part of modern European medicine has flowed. Galen was a man furnished with all the anatomical, medical and philosophical knowledge of his time; he had studied all kinds of natural curiosities, and had stood in near relation to important political events; he possessed an enormous industry, great practical sagacity and unbounded energy. He is described by later doctors, and lost no opportunity of depreciating regular medicine; nevertheless he has left many quotations from, and many details about, medical authors which are of the highest value. He is useful to us for what he wrote about the history of medicine, not for what he contributed. Like Celsus, he had little influence on succeeding medical literature or practice.

Galen was as devoted to anatomical and, so far as then understood, physiological research as to general practical medicine. He worked enthusiastically at dissection, though, the liberty of the Alexandrian schools no longer existing, he could dissect only animals, not the human body. In his anatomical studies Galen had a twofold object—a knowledge of the structure and of the functions of the parts, so as to serve its purpose; and, a practical, to aid the diagnosis, or recognition, of disease. The first led him into a teleological system so minute and overstrained as to defeat its own end; the second was successful only in some cases by generalization and certainty to medical and surgical practice in difficult cases. His general physiology was essentially founded upon the Hippocratic theory of the four elements, with which he combined the notion of stagnation (inflammation) penetrating all parts, and mingled with the humours in different proportions. It was on this field that he most vehemently attacked the prevailing atomistic and materialistic views of the methodic school, and his conception of the pneuma became in pathological research as to practical medicine. He reorganised special branches of physiology were important, but do not strictly belong to our present subject.

The application of physiology to the explanation of diseases, and thus to practice, was chiefly by the theory of the temperaments or mixtures which Galen founded upon the Hippocratic doctrine of humours, but developed with marvellous and fatal ingenuity. The normal condition or temperament of the body depended upon a proper mixture or proportion of the four elements—hot, cold, wet and dry. From faulty proportions of the same arose the insipidities ("distempers"), which, though not diseases, were the occasions of diseases. Equal proportions of all they were healthy. Faulty mixtures or dyscrasia of the blood. By a combination of the four, and so on different proportional mixtures of the elements, he was also enabled to show the disease of a single humour from without all diseases were produced. Galen showed extreme ingenuity in the same symptoms and signs of a single disease, and all diseases involved in the same system. No pheno
demon was without a name, no problem without a solution. And, though it was precisely in his fine-spun subtlety that he departed furthest from scientific method and practical utility, it was this very subtlety which made him, in the middle ages, a household name and the basis of Galen's reputation which was so widely prevalent through the ages.

Galen's use of drugs was influenced largely by the same theories. In drugs were to be recognized the same elementary qualities—hot,
cold, moist, dry, &c.—as in the human body; and, on the principle of curing by contraries, the use of one or other was indicated. The writings of Galen contain less of simple objective observations than those of several other ancient physicians, all being swept into the current of dogma and authority. The name of Galen was widely known and his name has fluttered the intellectual indolence of all ages. But the reputation of Galen grew slowly; he does not appear to have enjoyed any pre-eminence over other physicians of his time, to most of whom he was strongly opposed in opinion. In the next generation he became the first of the great medical philosophists, and his name was implicitly accepted, and it enjoyed a great though not exclusive pre-eminence till the fall of Roman civilization. When the Arabs possessed themselves of the scattered remains of Greek culture, Galen was most highly esteemed; and he is mentioned by almost every historian till the 13th century, when we meet with a group of writers. Demetrius Pappagomenus, Nicolaus Myrepsus and Johannes, called Actaursus, who flourished under the 13th century, and whose work has been much criticized for an independent judgment; but all are interesting as showing a fusion of Greek and Arabic medicine, the latter having begun to exercise influence in the 11th century a reflex influence on the schools of Byzantium. Something of the same nature occurred in the School of Salerno, where the close of Byzantine medicine is brought into connexion with the dawn of science in modern Europe.

In the West the period after Galen affords little evidence of anything but a gradual though unvarying decline in Roman medicine. Galen, Orhydrus, already referred to as the 14th century, must be mentioned as showing the persistence of the methodic school. An abridgment of one of his writings, with the title of Aurelius, became the most popular of all Latin medical works. As a writer he was worthy of a better period of medical literature. Little else was produced in these times but compilations, of the most meagre kind, chiefly of the nature of herbs, or domestic receipts: books; among the authors of which it may be sufficient to name Nicolaus of Cusmaenius, Galen, Orhydrus and Marcellus Empiricus (5th century). Certain compilations still extant bear the falsely-assumed names of eminent writers, such as Pliny and Hippocrates. A writer with the (perhaps assumed) name of the 13th century, Aventinus, seems to have come very near, to the 13th century, at least, and was in the 9th translated into Anglo-Saxon. These poor compilations, together with Latin translations of certain works of Galen and Hippocrates, formed a medical literature for the 16th century, which was more or less a great part survived through the middle ages till the discovery of printing and revival of learning. It is important to remember that this obscure stream of tradition flowed on, only partially affected by the influx of Arabian, or even the early revival of purer classical learning.

Arabian Medicine.—The rise of the Mahomedan Empire, which influenced Europe so deeply both politically and intellectually, made its mark also in the history of medicine. As in the parallel case of the Roman conquest of Greece, the superior culture of the conquered race asserted its supremacy over their Arab conquerors. After the Mahomedan conquests became consolidated, and learning began to flourish, schools of medicine, often connected with hospitals and schools of pharmacy, arose in all the chief seats of Moslem power. At Damascus Greek medicine was zealously cultivated with the aid of Jewish and Christian teachers. In Bagdad, under the rule of Harun el Rashid and his successors, a still more flourishing school arose, where numerous translations of Greek medical works were made. The names of Mesua, or Yahyâ ibn Masawayh (d. A.D. 857–858), celebrated for his knowledge of drugs, and Bonein ibn Ishâq el 'Ibâdî (d. 873) or Joannitius, the translator and commentator of Hippocrates and Galen, belong to this period. Certain writings of Joannitius, translated into Latin, were popular in the middle ages in Europe, and were printed in the 16th century. At the same time the Arabs became acquainted with Indian medicine, and Indian physicians lived at the court of Bagdad. The influence of the Moslems in the Middle East in encouraging learning and medical science, and developed culture to a still higher degree of perfection. In that country much was due to the Jews, who had already established schools in places which were afterwards the seats of Moslem dominion. From the 10th to the 13th century was the brilliant period of Arabian medicine in Spain.3

The classical period of Arabian medicine begins with Razes (Abû Bakr Muhammad ibn Zakâriya al-Razi, A.D. 925–926), a native of Raî in the province of Shâmir (Persia), who practised with distinction at Bagdad; he followed the doctrines of Galen, but learnt much from Greek medicine. His work on surgery, must have been considerably in advance of his time; it is a comprehensive and encyclopaedic manner, surpassing probably in its completeness Galen himself, but at a small proportion of his works are extant. Razes is deservedly remembered as having compiled a compendium of the scientific knowledge which existed in his time, under the title of 'Ali ibn el-'Abbâs, a Persian, wrote a medical textbook, known as the "Royal Book," which was the standard authority among the Arabs up to the time of Avicenna (A.D. 980–1037) and was more than once translated into Latin and printed. writers of this century need not be mentioned here; but the next,
the 11th century, is given as the probable though uncertain date of
a writer who had a great influence on European medicine, Mesuia
the younger of Damasc, whose personality is obscure, and of whose
very existence some historians have doubted, thinking the name
Abu'l-Qasim, by which he is known, a pseudonym. His only
work, *Ala'is-fur*, a medical encyclopaedia, is chiefly valued for
its surgical portion (already mentioned), which was translated into
Latin in the 16th century, and was for some centuries a standard
work, *Ala's-sir* (Canons), is an encyclopaedia of medical
and surgical knowledge, founded upon Galen, Aristotle,
the later Greek physicians, and the earlier Arabian writers, singularly
complete and accurate; but it is not a work to which the Arabian
experience of its author. As in the case of Galen, the formal
and encyclopaedic character of Avicenna's works was the chief cause
of his popularity and ascendancy, though in modern times these
very qualities in a scientific or medical writer would rather cause
him to be regarded rather as the father of medical literature.

In the long list of Arabian medical writers none can here be
mentioned except the great names of the Hispano-Moorish school,
abundantly discussed in the previous chapter. Of the earliest
works of this school, the most famous, and the work of
which he is chiefly known, the celebrated *Al-Mansur*, is an
encyclopaedia of medical and surgical knowledge, founded upon
Galen and Celsus, the later Greek physicians, and the earlier
Arabian writers, singularly complete and accurate; but it is not a work
which the Arabian experience of its author. As in the case of Galen,
the formal and encyclopaedic character of Avicenna's works was the chief cause
of his popularity and ascendancy, though in modern times these
very qualities in a scientific or medical writer would rather cause
him to be regarded rather as the father of medical literature.

The works of the Arabian medical writers who have now been
mentioned form a very small fraction of the existing literature.

The works of the Arabian medical writers who have now been
mentioned form a very small fraction of the existing literature.

The works of the Arabian medical writers who have now been
mentioned form a very small fraction of the existing literature.

The works of the Arabian medical writers who have now been
mentioned form a very small fraction of the existing literature.
Among the writers it may be sufficient to mention here Gariopontus; Cepho, who wrote the *Anatome porci*, a well-known medieval book; Joannes Platearius, first of a family of physicians bearing the same name, whose *Practica*, or medical compendium, was afterwards seven times translated in the Latin tongue; and finally, the last-named. All of these fell into the first period before the advent of Arabian medicine. In the transitional period, when the Arabian school began to influence European medicine, but before the Salernitans and Bolognesi had introduced the *Antidotarium*, a collection of formulae for compound medicines, which became the standard work on the subject, and the foundation of many later compilations. An equally popular writer was Gilles de Corbeil, who was described by a contemporary as the chief of the school at Salerno, afterwards court physician to Philip Augustus of France, who composed several poems in Latin hexameters on medical subjects. Of two, them, on the urine and the pulse respectively, attained the position of medical textbooks. None of these Salernitan works rise much above the rank of compilations, being founded on Hippocrates, Galen and later Greek writers, with an unmistakable mixture of the doctrines of the methodists. But they often show much practical experience, and exhibit the naturalistic method of the Hippocratic school. The general plan of treatment is dietetic rather than pharmaceutical, though the art of preparing drugs had reached a high degree of complexity at Salerno. Anatomy was as little regarded as it was in the later ancient schools, the empirical and methodic, but demonstrations of the parts of the body were given on swine. Although it cannot be said that the science of medicine was advanced at Salerno, a fact which was admitted by the same medical writer who described Galen as the founder of medicine, it was in its very state of inferiority that Arabian medicine, more direct than less conscious than that more research, was made use of in teaching and practice. The school of Salerno thus forms a bridge between the ancient and the modern medicine, more direct though less conscious than that circuitous route, through Byzantium, Bagdad and Cordova, by which Hippocrates and Galen, in Arabic dress, again entered the Western world, though by the middle of the 14th century the school actually existed till it was finally dissolved by an edict of the emperor Napoleon I in the year 1811.

**Introduction of Arabian Medicine. The Scholastic Period.**

— Among the middle of the 11th century the Arabian medical writers began to be known by Latin translations in the Western world. Constantinus Africanus, a monk, was the author of the earliest of such versions (A.D. 1050); his labours were directed chiefly to the less important and less bulky Arabic authors, of whom Haly was the most noted; the real classics were not introduced till later. For some time the Salernitan medicine held its ground, and it was not till the conquest of Toledo by Alphonso of Castile that any large number of Western scholars came in contact with the learning of the Spanish Moors, and systematic efforts were made to translate their philosophical and medical works. Jewish scholars, often under the patronage of the Moorish sovereigns, were the foremost in this work. Sicily also the Oriental tendencies of Frederick Barbarossa and Frederick II. worked in the same direction. Gerard de Cremona, a physician of Toledo (1114-1187), made translations, it is said by command of Barbarossa, from Avicenna and others. It is needless to point out the influence of the crusades in making Eastern ideas known in the Western world. The influence of Arabian medicine soon began to be felt even in the Hippocratic city of Salerno, and in the 13th century is said to have held an even balance with the older medicine. After this time the foreign influence predominated; and by the time that the Aristotelian dialectic, in the introduction of which the Arabs had so large a share, prevailed in the schools of Europe, the Arabian version of Greek medicine reigned supreme in the medical world. That this movement coincided with the establishment of some of the older European universities is well known. The history of medical thought in the middle ages is closely connected with the history of scholastic philosophy. Both were infected with the same dialectical subtlety, which was, from the nature of the subject, especially injurious to medicine.

At the same time, through the rise of the universities, medical learning was much more widely diffused, and the first definite forward movement was seen in the school of Montpellier, where a medical faculty existed early in the 12th century, afterwards united with faculties of law and philosophy. The medical school owed its foundation largely to Jewish teachers, themselves educated in the Moorish schools of Spain, and imbued with the intellectual independence of the Averroists. Its rising prosperity coincided with the decline of the school of Salerno. Montpellier became distinguished for the practical and empirical spirit of its medicine, as contrasted with the dogmatic and scholastic teaching of Paris and other universities. In Italy, Bologna and Padua were earliest distinguished for medical studies—the former preserving more of the Galenic tradition, the latter being more progressive and Averroist. The northern universities contributed little—the reputation even of Paris being of later growth.

The supremacy of Arabian medicine lasted till the revival of learning, when the study of the medical classics in their original language worked another revolution. The medical writers of this period, who chiefly drew from Arabian sources, have been called Arabists (though it is difficult to give any clear meaning to this term), and were afterwards known as the neotereics.

The medical literature of this period is extremely voluminous, but essentially second-hand, consisting mainly of commentaries on Hippocrates, Galen, Avicenna and others, or of compilations and *compendia* still less original than commentaries. Among these may be mentioned *The Consiliorium of Peter of Abano* (1250-1315), the *Aggregatio of Jacob of Salerno* of 1299, the *School of the Padua*, and the *Pandectae medicinae* of the Salernitan Matthaeus Sylvestris (d. 1342), a sort of medical vocabulary and dictionary. And for us the most interesting fact is the first appearance of Englishmen in medical practice. The Englishman of this period was distinguished, according to the testimony of Hâser, by a practical tendency characteristic of the British race, and fostered in the school of Montpellier.

Of these works is the *Compendium medicinae*, also called *Laurea or Rosa anglica*, of Gilbert (Gilbertus Anglicus, about 1290), said to contain good observations on leprosy. A more important work, the *Practica seu lilium medicinae*, of Bernard Gordon, a pupil of Alphonso of Salerno, was at one time very popular in Florence, and was, more widely spread, being translated into French and Hebrew, and printed in several editions. Of these two physicians the first probably, the latter certainly, was educated and practised abroad, but John Gentilis (d. 1615), author of the *Practica medicinae* (between 1305 and 1317), was a graduate in medicine of Merton College, Oxford, and court physician. His *compendium* is entirely wanting in originality, and perhaps usually the least of commentaries, but it became for a time the standard, and was reprinted up to the end of the 16th century. Works of this kind became still more abundant in the 14th and in the first half of the 15th century, till the wider distribution of the medical classics in the original put them out of fashion.

In surgery this period was far more productive than in medicine, especially in Italy and France, but the limits of our subject only permit us to mention Guillelmus de Saliceto of Placentia (about 1275), Lawrence of Ciudad (d. 1368), Guy de Mandeville (d. 1290), Chauliac (about 1350) and the Englishman, John Arderon (about 1350). In anatomy also the beginning of a new epoch was made by Mondino de Liucii or Mundinus (1275-1326), and his followers. Though the *Breviarium practice medicinae* (if the *Breviarium practicae* be rightly ascribed to him) rise above the rank of compilations. Finally, in the 13th and especially the 14th century we find, under the name of *consilia*, the first medieval reports of medical cases which are preserved in such a form as to be intelligible. Collections of *consilia* were published, among others, by Gentiles Fulgentius before 1348, by Bartolomeo Montagnana (d. 1470), and by Baeverus de Bavaria of Imola (about 1450). The last-named contains much that is interesting and readable.

**Period of the Revival of Learning.**—The impulse which all departments of intellectual activity received from the revival of Greek literature in Europe was felt by medicine among the rest. Not that the spirit of the science, or of its corresponding practice, was at once changed. The basis of medicine through the middle ages had been literary and dogmatic, and it was literary and dogmatic still; but the medical literature, which from the 12th century, though on the whole it widened the works of Hippocrates and Galen, many of them hitherto unknown, and in addition the forgotten element of Latin medicine, especially the work of Celsus—was in itself far superior to the second-hand compilations and incorrect versions which had formerly been accepted as standards. The classical works, though still regarded with unreasoning reverence, were found to have a germinative and vivifying power that carried the mind out of the region of dogma, and prepared the way for the scientific movement which has been growing in strength up to our own day.
Two of the most important results of the revival of learning were indeed such as are excluded from the scope of this brief sketch—namely, the reawakening of anatomy, which to a large extent grew out of the study of the works of Galen, and the investigation of medicinal plants, to which a fresh impulse was given by the revival of Dioscorides (A.D. 50) and other ancient naturalists. The former brought with it necessarily a more accurate conception of physiology, and thus led up to the great discovery of Harvey, which was the turning-point in modern medicine. The latter gave rise, on the one hand, to the modern science of botany, on the other to a more rational knowledge of drugs and their uses. At the same time, the discovery of America, and increased intercourse with the East, by introducing a variety of new plants, greatly accelerated the progress both of botany and pharmacology.

But it was not in these directions that improvement was first looked for. It was at first very naturally imagined that the simple revival of classical and especially of Greek literature would at once produce the same brilliant results in medicine as in literature and philosophy. The movement of reform started, of necessity, with scholars rather than practising physicians—more precisely with a group of learned men, whom we may be permitted, for the sake of a name, to call the medical humanists, equally enthusiastic in the cause of letters and of medicine. From both fields they hoped to expel the evils which were summed up in the word barbarism. Nearly all medieval medical literature was condemned under this name; and for it the humanists proposed to substitute the originals of Hippocrates and Galen, thus leading back medicine to its fountain-head. Since a knowledge of Greek was still confined to a small body of scholars, and a still smaller proportion of physicians, the first task was to translate the Greek classics into Latin. To this work several learned physicians, chiefly Italians, applied themselves with great success. Among the early writers, Nicolaus Leonicenus of Vicenza (1428-1524), Giovanni de Monte or Montanus (1498-1552), and many others in Italy. In northern Europe should be mentioned Guilelmus Copus (1471-1532) and Günther of Andernach (1487-1534), better known as Guinterius Andernacensis, both for a time professors at Paris; and, among the greatest, Thomas Linacre (about 1460-1534; see LINACRE). A little later Janus Cornarius or Hagenbut (1500-1558) and Leonhard Fuchs (1501-1566) in Germany, and John Kaye of Caiaus (1510-1572) in England, carried on the work. Symphorien Champier (Champeus or Campeius) of Lyons (1472-1539), a contemporary of Rabelais, and the patron of Servetus, wrote with fantastic enthusiasm on the superiority of the Greek to the Arabian physicians, and possibly did something to enlist in the same cause the two far greater men just mentioned. Rabelais not only lectured on Galen and Hippocrates, but edited some works of the latter; and Michael Servetus (1511-1553), in a little tract Syroforum universa ratio, defended the practice of Galen as compared with that of the Arabs. The great Aldine Press made an important contribution to the work, by editions principes of Hippocrates and Galen in the original. Thus was the campaign opened against the medieval and Arabian writers, till finally Greek medicine assumed a predominant position, and Galen took the place of Avicenna. The result was recorded in a formal manner by the Florentine Academy, sometime shortly before 1535: "Quae, excusso. Arabicae et barbarae servitutis medicae jugo, ex professo se Galenicam appellavit et proffigato barbarorum exercitu unum totum et solum Galenum, ut optimum artis medicæ autorem, in omnibus se sequatur prollicita est." Janus Cornarius, from whom this is quoted, laments, however, that the Arabs still reigned in most of the schools of medicine, and that the Italian and French authors of works called Præcticæ were still in high repute. Among the triumph of Galenism was therefore not complete by the middle of the 16th century. It was probably most so, and earliest, in the schools of Italy and in those of England, where the London College of Physicians might be regarded as an offshoot of the Italian schools. Paris was the stronghold of conservatism, and Germany was stirred by the teachings of one who must be considered apart from all schools—Paracelsus. The nature of the struggle between the rival systems may be well illustrated by a formidable controversy about the rules for bleeding in acute diseases. This operation, according to the Arabian practice, was always performed on a vein at a distance from the organ affected. The Hippocratic and also Galenic rule, to let blood from, or near to, the diseased organ, was revived by Pierre Bristot (1470-1522), a professor in the university of Paris. His attempt at reform, which was taken to be, as in effect it was, a revolt against the authority of the Arabian masters, led to his expulsion from Paris, and the formal prohibition by the parliament of his method. Upon this apparently trifling question arose a controversy which lasted many years, occupied several universities, and led to the interposition of personages no less important than the pope and the emperor, but which is thought to have largely contributed to the final downfall of the Arabian medicine.

Paracelsus and Chemical Medicine.—Contemporary with the school of medical humanists, but little influenced by them, lived in Germany a man of strange genius, of whose character and importance the most opposite opinions have been expressed. The first noticeable quality in Paracelsus (c. 1490-1541) is his revolutionary independence of thought, which was supported by his immense personal arrogance. Himself well trained in the learning and medical science of the day, he despised and trampled upon all traditional and authoritative teachings. He began his lectures at Basel by burning the books of Avicenna and others; he afterwards boasted of having read no books for ten years; he protested that his shoe-buckles were more learned than Galen and Avicenna. On the other hand, he spoke with respect of Hippocrates, and wrote a commentary on his Aphorisms. In this we see a spirit very different from the enthusiasm of the humanists, who as a purer and wiser philosophy than the scholastic and Arabian version of Greek thought.

There is no record of Paracelsus' knowledge of Greek, and as, at least in his student days, the most important works of Greek medicine were very imperfectly known, it is probable he had little first hand acquaintance with Galen or Hippocrates, while his breach with the humanists is the more conspicuous from his lecturing and writing chiefly in his native German.

Having thus made a clean sweep of nearly the whole of the dogmatic medicine, what did Paracelsus put in its place? Certainly not pure empiricism, or habits of objective observation. He had a dogma of his own—one founded, according to his German expositors, on the views of the Neoplatonists, of which a few disjointed specimens must here suffice. The human body was a "microcosm" which corresponded to the "macrocosm", and contained in itself all parts of visible nature,—sun, moon, stars and the poles of heaven. To know the nature of man and how to deal with it, the physician should study, not anatomy, which Paracelsus utterly rejected, but all parts of external nature. Life was a perpetual germinative process controlled by the indwelling spirit or Archeus; and diseases, according to the mystical conception of Paracelsus, were not natural but spiritual. Nature was sufficient for the cure of most diseases; art had only to interfere when the internal physician, the man himself, was tired or incapable. Then some remedy had to be introduced which should be antagonistic, not to the disease in a physical sense, but to the spiritual seed of the disease. These remedies were arcana—a word corresponding partly to what we now call specific remedies, but implying a mysterious connexion between the remedy and the "esse" of the disease. Arcana were often shown to be such by their physical properties, not only by such as heat, cold, &c., but by fortuitous appearances to certain parts of the body; thus arose the famous doctrine of "signa theoriae," or signs indicating the aetiology and uses of natural objects, which was afterwards developed into great complexity. Great importance was also attached to chemically prepared remedies as containing the essence or spiritual quality of the material from which they were derived. The actual therapeutical resources of Paracelsus included a
large number of metallic preparations, in the introduction of some of which he did good service, and, among vegetable preparations, the tincture of opium, still known by the name he gave it, laudanum. In this doubtless he derived much advantage from his knowledge of chemistry, though the science was as yet not disentangled from the secret traditions of alchemy, and was often mixed up with imposture.

German historians of medicine attach great importance to the revolt of Paracelsus against the prevailing systems, and trace in his writings anticipations of many scientific truths of later times. That his personality was influential, and his intrepid originality of thought, is in his history undoubted; but his influence in the universal history of medicine we cannot estimate so highly. The chief immediate result we can trace is the introduction of antimony, which was used before the 17th century, and led to the expulsion of some men of mark from the Paris faculty. In England "chemical medicine" is first heard of in the reign of Elizabeth, and was in like manner condemned and assailed by the College of Physicians and the Society of Apothecaries. But it is not known that all the chemical physicians did not call Paracelsus master. The most notorious of that school in England, Francis Anthony (1590-1623), never quotes Paracelsus, but relies upon Arnold de Villisova and Raimon Luli. From this time onwards, it is always possible to trace a slyy antimony, local practitioners, who, though condemned by the orthodox Galenists, held their ground, till in the 17th century a successor of Paracelsus arose in the celebrated J. B. van Helmont.

Consequences of the Revival of Ancient Medicine.—The revival of Galenic and Hippocratic medicine, though ultimately it conferred the greatest benefits on medical sciences, did not immediately produce any important or salutary reform in practical medicine. The standard of excellence in the ancient writers was indeed far above the level of the 16th century; but the fatal habit of taking at second hand what should have been acquired by direct observation retarded progress more than the possession of better models assisted it, so that the fundamental faults of medieval science remained uncorrected.

Nevertheless some progress has to be recorded, even if not due directly to the study of ancient medicine. In the first place the 15th and 16th centuries were notable for the outbreak of certain epidemic diseases, which were unknown to the old physicians. Of these the chief was the "sweating sickness" or "English sweat," especially prevalent in, though not confined to, the country whence it is named. Among many descriptions of this disease, that by John Kaye or Caius, already referred to, was one of the best, and of great importance as showing that the works of Galen did not comprise all that could be known in medicine. The spread of syphilis, a disease equally unknown to the ancients, and the failure of Galen's remedies to cure it, had a similar effect.

In France and in Italy the foundations of modern medicine were being laid during the 16th century—namely, by the introduction of clinical instruction in hospitals. In this Italy, and especially the renowned school of Padua, took the first step, where Giovanni De Monte (Montanus), (1498-1552), already mentioned as a humanist, gave clinical lectures on the patients in the hospital of St Francis, which may still be read with interest. Pupils flocked to him from all European countries; Germans are especially mentioned; a Polish student reported and published some of his lectures; and the Englishman Kaye was a zealous disciple, who does not, however, seem to have done anything towards transplanting this method of instruction to his own country. Inspections of the dead, to ascertain the nature of the disease, were made, though not without difficulty, and thus the modern period of the science of morbid anatomy was ushered in.

Medicine in the 17th Century.—The medicine of the early 17th century presents no features to distinguish it from that of the preceding century. The practice and theory of medicine were mainly founded upon Hippocrates and Galen, with ever-increasing additions from the chemical school. But the development of mathematical and physical science soon introduced a fundamental change in the habits of thought with respect to medical doctrine.

These discoveries not only weakened or destroyed the respect for authority in matters of science, but brought about a marked tendency to mechanical explanations of life and disease. When William Harvey by his discovery of the circulation furnished an explanation of many vital processes which was reconcilable with the ordinary laws of mechanics, the efforts of medical theorists were naturally directed to bringing all the departments of medicine under similar laws. It is often assumed that the writings and influence of Bacon did much towards introducing a more scientific method into medicine and physiology. But, without discussing the general philosophical position or historical importance of Bacon, it may safely be said that his direct influence can be little traced in medical writings of the first half of the 17th century. Harvey, as is well known, spoke slightly of the great chancellor, and it is not till the rapid development of physical science in England and Holland in the latter part of the century, that we find Baconian principles explicitly recognized.

The dominant factors in the 17th-century medicine were the discovery of the circulation by William Harvey (published in 1628), the mechanical philosophy of Descartes and the contemporary progress of physics, the teaching of Van Helmont and the introduction of chemical explanations of morbid processes, and finally, combined of all these, and inspiring them, the rise of the spirit of inquiry and innovation, which may be called the scientific movement. Before speaking in detail of these, we may note that by other influences quite independent of theories, important additions were made to practical medicine. The method of clinical instruction in hospitals, commenced by the Italians, was introduced into Holland, where it was gradually developed, especially at Leyden, in the hands of Francis de la Boë, called Sylvius (1643-1672). It is noteworthy that concurrently with the rise of clinical study the works of Hippocrates were more and more valued, while Galen began to sink into the background.

At the same time the discovery of new diseases, unknown to the ancients, and the keener attention which the great epidemics of plague caused to be paid to those already known, led to more minute study of the natural history of disease. The most important disease hitherto undescribed was rickets, first made known by Arnold de Boot, a Frisian who practised in Ireland, in 1649, and afterwards more fully in the celebrated work of Francis Glisson (1597-1677) in 1651. The plague was carefully studied by Isbrand de Diemerbroek, in his De Peste (1649), and others. Nathaniel Hodges of London (1629-1668) in 1665 seems to have been the first who had the courage to make a post mortem inspection of a plague patient. Christopher Glisson (1655) made an important analysis of carboni consumption in 1654. During the same period some new remedies were introduced, the most important being cinchona-bark, brought to Spain in the year 1640. The progress of pharmacy was shown by the publication of Dispensatories or Pharmacopoeias—as such as that of the Royal College of Physicians of London in 1618. This, like the earlier German works of the same kind (on which it was partly founded), contains both the traditional (Galenical) and the modern or chemical remedies.

Van Helmont.—The medicine of the 17th century was especially distinguished by the rise of sytems; and we must first speak of an eccentric genius who endeavoured to construct a system for himself, the 17th century was dominated by the Cartesian philosophy, J. B. van Helmont (1678-1684) was a man of noble family in Brussels, who, after mastering all other branches of learning as he understood, devoted himself with enthusiasm to medicine and chemistry. By education and position a little out of the regular lines of the profession, he took up in medicine an independent attitude. Well acquainted with the doctrines of Galen, he rejected them as thoroughly as Paracelsus did, and borrowed from the latter some definite ideas as well as his revolutionary spirit. The archeus of Paracelsus
appears again, but with still further complications—the whole body being controlled by the \textit{archeus inflatus}, and the organ of the soul and its various parts by the \textit{archeis institi}, which are subject to the central arches. Many of the symptoms of diseases were caused by the action of one or another of these arches and meridians, and were therefore often cured by modifying the ideas of the same arches. These and other notions cannot be here stated at sufficient length to be intelligible. It is enough to say that on this fantastic basis Helmont constructed a method in which he had some good, concrete, and important processes and the result was to weak many and to make the work of medicine less than nothing. The use of new chemical methods was more widespread and made upon the human body, and was more in harmony with the ideas of the ancient physicians. Sylvin was the first, and was long the only instance of a great body by fermentation, and the explanation of many processes of life and disease. The sensory organs were involved in the general phenomena of life and death, and their processes depended upon different proportions, movements and combinations of these particles. The elaboration of work \textit{Pharmaceuticae rationalis} (1674), based on these materials, had much influence in its time, though it is long since forgotten. Some parts of Willis's works, such as his descriptions of nervous diseases, and the account of the earliest diabetes, are classical contributions to scientific medicine. In the application of chemistry to the examination of secretions Willis made some important steps. The chemical school of the 16th century, which neglected or denied the importance of ancient medicine, partly from the iatro-mechanical school. Towards the end of the 17th century appeared an English medical reformer who sided with none of these schools, but may be in some respects his benefactor. Sydenham and Locke.—Thomas Sydenham (1624-1689) was educated at Oxford and at Montpellier. He was well acquainted with the works of the ancient and modern physicians, and probably fairly so with those of the 16th century. Of his medical theory it may be said, as he seldom refers to it. His main avowed principle was to do without hypothesis, and study the actual diseases in an unbiased manner. As his model in medical methods, Sydenham may have had in mind the work of Hippocrates. Still, it is not the case, and although the Greek master in the high value he set on the study of the "natural history of disease," in the importance he attached to epidemic disease, and in the recognition of a common natural cause in causing disease; and further in his conception of the healing power of nature in disease, a doctrine which he even expanded beyond the teaching of Hippocrates. According to Sydenham, the only cure for disease was the "natural" one. His principles were welcomed as a relief to the artificial, arbitrary and difficult theoretical disputes. He introduced a milder and better way of treating fevers—especially small-pox, and gave strong support to the use of specific medicines—especially Peruvian bark. He was an advocate of bleeding, and was a great advocate of surgeon. His chief and most fundamental doctrine is his clear recognition of many diseases as being what would now be called specific, and not due merely to an alteration in the primary qualities of humors of the older schools. From the 18th century he is regarded as the father of modern medicine.

One name should always be mentioned along with Sydenham—that of his friend John Locke. The great sensational philosopher was a thoroughly trained physician, and practised privately. He never wrote a book on medical science, but his medical observations have left him a great mark in the history of medicine. In his works he frequently mentions the use of medical science, little good was done by the pretended application of these half-understood principles to practice. The reform of medical practice was effected by men who aimed at, and partly succeeded in, ejecting all hypothesis and returning to the unbiased study of nature. From this time forth the reign of canonical authority in medicine was at an end, though the dogmatic spirit long survived.

The 18th Century.—The medicine of the 18th century is notable, like that of the latter part of the 17th, for the striving
after complete theoretical systems. The influence of the iatro-
physiological school was by no means exhausted; and in
England, especially through the indirect influence of Sir Isaac
Newton's (1642-1727) great astronomical generalizations, it
took on a mathematical aspect, and is sometimes known as
iatro-mathematical. This phase is most clearly developed in
Archibald Pitcairne (1652-1713), who, though a determined
opponent of metaphysical explanations, and of the chemical
doctrines, gave to his own rude mechanical explanations of life
and disease almost the dogmatic completeness of a theological
system. His countryman and pupil, George Cheyne (1671-
1743), who lived some years at Bath, published a new theory of
fevers on the mechanical system, which had a great reputation.
Their English contemporaries and successors, John Freind,
William Cole, and Richard Mead, leaned also to mechanical
explanations, but with a distrust of systematic theoretical
completeness, which was perhaps partly a national character,
partly the result of the teaching of Sydenham and of
Freind (1675-1728) in his Enneemologia gave a mechanical
explanation of the phenomena of menstruation. He is
one of the most distinguished writers on the history of medicine.
Coe (1635-1716) (see above) published mechanical hypotheses
concerning the causation of fevers which closely agree with those
of the Italian iatro-mechanical school. More distinguished
in his own day than any of these was Mead (1673-1754), one
of the most accomplished and socially successful physicians
of modern times. Mead was the pupil of the equally popular
and successful John Radcliffe (1650-1714), who had acquired
from Sydenham a contempt for book-learning, and belonged
to no school in medicine but the school of common sense.
Rad-
cliffe left, however, no work requiring mention in a history of
medicine. Mead, a man of great learning and intellectual
activity, was an ardent advocate of the mathematical
doctrines.

It is evident, he says, "that all other means of inquiring into
the true causes of disease, have been found ineffectual, by the stand it was
at for two thousand years, and that, since mathematicians
have set themselves to the study of it, men already begin
to talk intelligibly and comprehensibly, even about abstruse
matters, that it is to be hoped that mathematical learning
will be the distinguishing mark of a physician and a quack."
His Mechanical Account of Poisons, in the first edition (1702),
gave an explanation of the effects of poisons, as acting on
the blood. Afterwards he modified his hypothesis, and
referred the disturbances produced to the "nervous liquor," which he supposed to be a quantity of the "universal elastic
matter" diffused through the universe, by which Newton explained the phenomena of light—i.e., what was afterwards
called the luminiferous ether. Mead's treatise on The Power of
Sick and Healthy Human Bodies (1704), equally inspired by
Newton's discoveries, was a premature attempt to assign
the influence of atmospheric pressure and other cosmical
causes in producing disease. His works contain, however, many
original experiments, and excellent practical observations.
James Keill (1673-1719) applied Newtonian and mechanical
principles to the explanation of bodily functions with still
greater accuracy and completeness; but his researches have more
importance for physiology than for practical medicine.

Boerhaave—None of these men founded a school—a result due in
great part to their intellectual character, in part to the absence
in England of medical schools equivalent in position and importance
to the universities of the Continent. An important academic
position was, on the other hand, one of the reasons why a physician
not unfrequently attained literary distinction, and was called to
aid in the education of the sons of the nobility. The death of the age of Queen Anne was able to take a far more predominant
position in the medical word. Hermann Boerhaave (1668-1738)
was emphatically a great teacher. He was for many years professor
of medicine at Leyden, and had attained to that position by 1711,
excelled in influence and reputation not only his greatest
followers, Montaus of Padua and Sylvius of Leiden, but probably
even more his subsequent teachers. The hospital of Leyden, though with
only two beds available for teaching, became the centre of
medical influence in Europe. Many of the leading English physicians
of the 18th century studied there; Gerard Van Swieten (1700-
1772), a pupil of Boerhaave, transplanted the latter's method of
teaching to Vienna, and founded the noted Vienna school of
medicine.

As the organizer, and almost the constructor, of the modern method
of clinical instruction, the services of Boerhaave to the progress of
medicine were immense, and can hardly be overrated. In his teaching,
as in his practice, he avowedly followed the method of Hippo-
crates and of his contemporary, the theoretician Sydenham. He thus differed from Sydenham, who took almost no
account of modern science as of ancient dogmas. Boerhaave
may be, in some respects compared to Galen, but again differed
from him in that he always abstained from attempting to reduce his
theories to exact demonstrable propositions. He had attached
great importance to the study of the medical classics, but rather treated, them historically than quoted them as
canonical authorities. It almost follows from the nature of the case that the
"physicians of Boerhaave's life," a synthesis of ancient and modern
medicine, and the work in which this is chiefly contained, his
celebrated Institutions, could not have any great permanent value.
Near the same thing is true even of the Aphorisms, in which,
following the example of Hippocrates, he endeavoured to sum up
the results of his long experience.

Hoffmann and Stahl.—We have now to speak of two writers in
whom the systematic tendency of the 18th century showed itself
more completely.

Friedrich Hoffmann (1660-1742), like Boerhaave, owed his
influence, and perhaps partly his intellectual characteristics, to
his academic position. He was in 1703 appointed the first
professor of medicine at the university of Vienna, which had
been founded by the emperor Frederick III. Here he became, as did his temporary
and rival Stahl, a popular and influential teacher, though their university had not the European importance of
Hoffmann's. He, like Boerhaave, was an ardent advocate of the composing
"spiritual " and "materialistic" views of nature, and is thought
to have been much influenced by the philosophy of Leibnitz. His
medical theories rest upon a complete theory of the universe.
Life depends on the nourishment of the body, which is received both
from the air and from the earth. In the earth is the "nervous fluid
or pneuma, a doctrine closely resembling that of Mead on the
"nervous liquor,"

On this system are explained all the phenomena of life and disease.
Health depends on the maintenance of a proper "tone" in the
body—some diseases being produced by excess of tone, or "spasm";
while others are due to there being too little or none to
follow its further developments. Independently of his system, which
has long ceased to exert any influence, Hoffmann made some
contributions to practical medicine; and his great knowledge of
minerals, enabled him to write a valuable work on mineral waters.
He was equally skillful in pharmacy, but lowered the reputation by
the practice, which would be unpronounceable in a modern physician,
of trafficking in secret remedies.

George Ernst Stahl (1659-1734) was for more than twenty
years professor of medicine at Halle, and thus a colleague of
Hoffmann, whom he resembled in constructing a complete theoretical
system, though their systems had little or nothing in common.
Stahl, chief of the "phlogiston" theory, laid the foundation
of modern chemistry. For mechanical conceptions he substituted the theory of "phlogiston," attributing to it an influence
by the soul the functions of ordinary animal life in man, while the life of other creatures was left to mechanical laws. The
symptoms of disease were explained as efforts of the soul to rid itself from
morbid influences, the soul acting reasonably with respect to the
end of self-preservation. The anima thus corresponds partly to the
"nervous fluid of Sydenham, but in other respects it resembles
the "pneuma of Boerhaave. Its completeness was met with little acceptance during the lifetime of Stahl, but it
influenced some of the iatro-physiological school. Stahl was the author of
the theory of "phlogiston" in chemistry, which in its day had
great importance.

Haller and Morgagni.—From the subjection of rival systems it is
a satisfaction to turn to two movements in the medicine of the
18th century, though they did not extinguish the spirit of
system-making, opened up paths of investigation by which the
physician has been enabled to approach with much more
modern sense, as dating from Haller, and pathological anatomy,
as dating from Morgagni.

Albrecht von Haller (1708-1777) was a man of even more encyclo-
dermic than either Boerhaave or Stahl. He advanced chemistry,
botany, anatomy, as well as physiology, and was incessantly
occupied in endeavouring to apply his scientific studies to
practical medicine, thus continuing the work of his great teacher Boerhaave.

Besides all this he was probably more profoundly acquainted with
the literature and bibliography of medicine than any one before
or since. Haller occupied in the new university of Göttingen
(founded 1737) a position corresponding to that of Boerhaave at
Leiden, and in like manner influenced a very large circle of pupils.
The appreciation of his work in physiology belongs to the history of that science; we are only concerned here with its influence on medicine. The doctrine of irritable substances or exciting propensities, and its distinction from sensibility as a property of nerves, struck at the root of the prevailing hypothesis respecting animal activity. It was no longer necessary to suppose that a half-consciousness, in the nervous system, being discharged as without but only the need of contriving other "systems" less open to objection; and thus the influence of Haller led directly to the theoretical subtleties of William Cullen and John Brown, and only indirectly to theories of the nervous system. For, mythically speaking, the name of Haller does not therefore occupy a very prominent place in the history of practical medicine.

The work of Giovanni Battista Morgagni (1682-1771) had and still has a place among the system-building of contemporary theorists. In a series of letters, De sedibus et causis morborum per anatomen indagatis, published when he was in his eightieth year, he describes the appearances met with at the post mortem examination, as well as the symptoms during the course of a number of cases of various diseases. It was not the first work of the kind. The Swiss physician, Théophile Bonet (1620-1669) had published his Sepulchrum in 1679; and observations of post mortem examination had been kept by van Leeuwenhoek, Raymond Vieussens, A. M. Valsalva, G. M. Lancisi, Haller and others. But never before was so large a collection of cases brought together, described with such accuracy, or illustrated with equal ability, as is to be found in Morgagni. He had made an epoch in the science. Morbid anatomy now became a recognized branch of medical research, and the movement which has lasted till our own day.

The doctrine that physiology must be regarded as in some respects the counterpart of Sydenham's. The latter had, in neglecting anatomy, neglected the most solid basis for studying the natural history of disease; though perhaps it was less from choice than because his practical experience was limited. Anatomist, Haller gave him no opportunities. But it is on the combination of the two methods—that of Sydenham and of Morgagni—that modern medicine rests; and it is through these that it has been able to make strides in the medical field, independently of the advances of physiology or other sciences.

The method of Morgagni found many imitators, both in his own country, in England, and in France. In England, the first important name in this field is at the same time that of the first writer of a systematic hospital, gave him no opportunities. But it is on the combination of the two methods—that of Sydenham and of Morgagni—that modern medicine rests; and it is through these that it has been able to make strides in the medical field, independently of the advances of physiology or other sciences.

The method of Morgan
"similia similibus curantur," which he explained as depending on the law that in order to get rid of a disease some remedy must be given which should substitute for the disease an action dynamically similar, but weaker. The original malady being thus got rid of, the vital force would easily be able to cope with and extinguish the disease in a distance caused by the remedy. Hence a disease very similar was held by Brown, who taught that "indirect debility" was to be cured by a lesser degree of the same stimulus as had caused the original disturbance. Generally, however, Hahnemann varied the dosis according to the time and force of the patient, to the same plane. In order to select remedies which should fulfill the indication of producing symptoms like those of the disease, Hahnemann made many observations of the action of drugs on healthy persons. But these innovations were quite independent of the truth or falsity of his theoretical system.

Positive Progress in the 18th Century.—In looking back on the repeated attempts in the 18th century to construct a universal system of medicine, it is impossible not to regret the waste of many years and profound acquirements which they involved. It was fortunate, however, that the accumulation of positive knowledge in medicine did not cease. While Germany and Scotland, as the chief homes of abstract speculation, gave birth to most of the theories, progress in objective science was most marked in other countries—in Italy first, and afterwards in England and France. We must retrace our steps a little to enumerate several distinguished names which, from the nature of the case, hardly admit of classification.

In Italy the tradition of the great anatomists and physiologists of the 17th century produced a series of accurate observers and practitioners. Among the first of these were Antonio Maria Valsalva (1666-1733), still better known as an anatomist; Giovanni Maria Lancisi (1654-1700), also an anatomist, the author of a classical work on the diseases of the heart and aneurisms; and Ippolito Francesco Albertini (1662-1738), whose researches on the same class of diseases were no less important.

In France, Jean Baptiste Sénac (1603-1770) wrote also an important work on the affections of the heart. Sauvages, otherwise F. B. de Lacroix (1706-1767), gave, under the title *Necologia methodica*, a natural-history classification of diseases; Jean Astruc (1684-1766) contributed to the knowledge of general diseases. But the state of medicine in that country till the end of the 18th century was unsatisfactory as compared with some other parts of Europe.

In England the brilliancy of the early part of the 18th century in practical medicine was hardly maintained to the end, and presented, indeed, a certain contrast with the remarkable and unflagging progress of surgery in the same period. The roll of the College of Physicians does not furnish many distinguished names. Among these should be mentioned John Fothergill (1712-1780), who, though an advocate of the use of vegetable stimulants, was opposed to the use of bloodletting. Another who offered interesting observations on the disease now called diphtheria, and the form of neuralgia popularly known as tic douloureux. A physician of Plymouth, John Hurham (1694-1768), made researches on epidemic fevers, in the spirit of Sydenham and Hippocrates, which are of the highest importance. William Heberden (1710-1801), a London physician, called by Samuel Johnson *ultimus Romanorum,* "the last of our learned physicians," left a rich legacy of practical observations in the *Commentaries* published after his death. More important in their results than any of these works were the discoveries of Edward Jenner (q.q.), respecting the prevention of small-pox by vaccination, in which he superseded the partially useful but dangerous practice of inoculation, which had been introduced into England in 1721. The history of this discovery need not be told here, but it may be pointed out that, apart from its practical importance, it has had great influence on the scientific study of infectious diseases. The name of John Pringle (1707-1782) should also be mentioned as one of the first to study epidemics of fevers occurring in prisons and camps. His work, entitled *Observations on the Diseases of an Army*, was translated into many European languages and became the standard authority on the subject.

In Germany the only important school of practical medicine was that of Vienna, as revived by Gerard van Swieten (1700-1772), a pupil of Boerhaave, under the patronage of Maria Theresa. Van Swieten's commentaries on the aphorisms of Hippocrates are thought more valuable than the original text. Other eminent names of the same school are Anton de Haén (1704-1776), Anton Störck (1723-1803), Maximilian Stoll (1742-1788), and John Peter Frank (1745-1821), father of Joseph Frank, before mentioned as an adherent of the Brownian system, and like his son carried away for a time by the new doctrines. This, the old "Vienna School," was not distinguished for any notable discoveries, but for success in clinical teaching, and for its sound method of studying the actual facts of disease during life and after death, which largely contributed to the establishment of the "positive medicine" of the 19th century.

One novelty, however, of the first importance is due to a Vienna physician of the period, Leopold Auenbrugger (1722-1809), the inventor of the method of recognizing diseases of the chest by percussion. Auenbrugger's method of direct percussion with the tips of the fingers, not that which is now used, of mediate percussion with the intervention of a finger or pleximeter; but the results of his method were the same and its value nearly as great. Auenbrugger's great work, the *Inventum novum,* was published in 1761. The new practice was received at first with contempt and even ridicule, and afterwards by Stoll and Peter Frank with only grudging approval. It did not receive due recognition till 1808, when J. N. Corvisart translated the *Inventum novum* into French, and Auenbrugger's method rapidly attained a European reputation. Surprised, but not eclipsed, by the still more important art of auscultation introduced by R. T. H. Laennec, it is hardly too much to say that this simple and purely mechanical invention has had more influence on the development of modern medicine than all the "systems" evolved by the most brilliant intellects of the 18th century.

Rise of the Positive School in France.—The reform of medicine in France must be dated from the great intellectual awakening caused by the Revolution, but more definitely starts with the researches in anatomy and physiology of Marie François Xavier Bichat (1771-1802). The importance in science of Bichat's classical works, especially of the *Anatomie générale,* cannot be estimated here; we can only point out their value as supplying a new basis for pathology or the science of disease. Among the most ardent of his followers was François Joseph Victor Broussais (1772-1838), whose theoretical views, partly founded on those of Brown and partly on the so-called vitalist school of Théophile Bordeaux (1722-1776) and Paul Joseph Barthéz (1734-1806), differed from these essentially in being avowedly based on anatomical observations. Broussais's chief aim was to find an anatomical basis for all diseases, but he is especially known for his contributions to the subject of irritation or inflammation of the intestinal canal (gastroenterite). A number of other maladies, especially general diseases and those commonly regarded as nervous, were attributed to the same cause. It would be impossible now to trace
MEDICINE

James Nicol Corvisart (1755–1821) has already been mentioned as the translator and introducer into France of Auenbrugger's work on percussion. He introduced some improvements in the method, but the only real advance was the introduction of mediate percussion by his disciple, Anton Louis Rosta"n (1790–1828). The discovery had, however, yet to be completed by that of auscultation, or listening to sounds produced in the chest by breathing, the movements of the heart, etc. The combination of these methods constituted an anatomical bleeding. It was thus that the invention of the stethoscope was achieved. The discovery had been complete in his work De l'a"uscultation m"edicate, published in 1819. Laennec attached undue importance to the use of the stethoscope, and laid too much weight on specific signs of specific disease. There is no doubt that the method was improved, but the original features of the instrument remained unchanged. The result of his discovery was an entire revolution in the knowledge of diseases of the chest; but it would be a mistake to forget that an essential factor in this revolution was the simultaneous and independent discovery of the disease of the organs as seen after death. Without the latter, it is difficult to see how the great advance made by Gaspard Laurent Bayle (1774–1816), whose researches on tuberculosis, and the changes of the lungs and other organs in consumption, are the foundation of most that has been done since his time. It was of course an indispensable concomitant to the discovery of auscultation. Starting from these men arose a school of physicians who endeavoured to give to the study of symptoms the same precision as belonged to anatomical observations, and by the combination of these methods a new era in clinical medicine was inaugurated. Among these were Auguste François Chomel (1778–1858), Pierre Charles Alexandre Louis (1778–1872), Jean Cruveilhier (1791–1874) and Gabriel Andral (1797–1876). Louis, by his researches on pulmonary disease, brought to light the chief manifestations of the disease of the lungs, and laid the foundations of the doctrines of Broussais. In another respect also he aided in establishing an exact science of medicine by the introduction of the numerical or statistical method. By this method only can the facts of medicine be studied with precision in the description of cases shown to be avoided; and thus the chief objections which were made to regarding medicine as an inductive science have been removed. Louis's method was improved and systematized by Louis Denis Jules Gavarret (1809–1890); and its utility is now universally recognized. During this brilliant period of French medicine the superiority of the school of Paris could hardly be contested. We can only mention the names of Pierre Bretonneau (1792–1842), Jean Louis D'Alibert (1765–1837), Pierre François Olive Rayer (1761–1829), and Armand Trouseau (1801–1866), the eloquent and popular teacher.

English Medicine from 1800 to 1840.—The progress of medicine in England during this period displays the same characteristics as at other times, viz., a gradual and uninterrupted development, without startling changes such as are caused by the sudden rise or fall of a new school. Hardly any theoretical system is of English birth; Erasmus Darwin (1731–1802), the grandfather of the great Charles Darwin, alone makes an exception. In his Zoonomia (1794) he expounded a theory of life and disease which had some resemblance to that of Brown, though arrived at (he says) by a different chain of reasoning.

Darwin's work shows, however, the tendency to connect medicine with physical science, which was an immediate consequence of the scientific discoveries of the end of the 18th century, when Priestley and Cavendish in England exercised the same influence as Lavosier in France. The English school of medicine was also profoundly stirred by the teachings of the Frenchmen William and John Hunter, especially the latter—who must therefore be briefly mentioned, though their own researches were chiefly concerned with subjects lying a little outside the limits of this sketch. William Hunter (1718–1783) was known in London as a brilliant teacher of anatomy and a successful obstetric physician; his younger brother and pupil, John Hunter (1728–1793), was also a teacher of anatomy, and practised as a surgeon. His immense contributions to anatomy and pathology cannot be estimated here, but his services in stimulating research and training investigators belong to the history of general medicine. They are sufficiently evidenced by the fact that Edward Jenner and Matthew Baillie were his pupils.

The same scientific bent is seen in the greater attention paid to morbid anatomy (which dates from Baillie) and the more scientific method of studying diseases. An instance of the latter is the work of Robert Willan (1757–1812) on diseases of the skin—a department of medicine in which abstract and hypothetical views had been especially injurious. Willan, by his introduction of the normal-history method of Sydenham, at once put the study of diseases on a true and scientific footing, and is the starting-point of the most important modern researches. About the same time William Charles Wells (1757–1817), a scientific investigator of remarkable power, and the author of a celebrated essay on dew, published observations on alterations in the urine, which, though little noticed at the time, were of great value as assisting in the important discovery made some years afterwards by Richard Bright.

These observers, and others who cannot be mentioned here, belong to the period when English medicine was still little influenced by the French school. Shortly after 1815, however, when the continent of Europe was again open to English travellers, many English doctors studied in Paris, and the discoveries of their great French contemporaries began to be known. The method of auscultation was soon introduced into England by the pupils of Laennec. John Forbes (1787–1861) in 1824, and William Augis (1804–1878) of Dublin in 1825, published treatises on the use of the stethoscope. Forbes also translated the works of Laennec and Auenbrugger, and an entire revolution was soon effected in the knowledge of diseases of the chest. James Hope (1801–1841) and Peter Mere Latham (1789–1875) further developed this subject, and the former was also known for his researches in morbid anatomy. The combination of clinical and anatomical research led, as in the hands of the great French physicians, to important discoveries by English investigators. The discovery by Richard Bright (1789–1858) of the disease of the kidneys known by his name proved to be one of the most momentous of the century. It was published in Reports of Medical Cases 1827–1831. Thomas Addison (1793–1860) takes, somewhat later, a scarcely inferior place. The remarkable physiological discoveries of Sir Charles Bell (1774–1842) and Marshall Hall (1790–1857) for the first time rendered possible the discrimination of diseases of the spinal cord. Many of these physicians were also eminent for their clinical teaching, an art in which Englishmen had up till then been greatly deficient. Although many names of scarcely less note might be mentioned among the London physicians of the early part of the century, we must pass them over. Among the more numerous medical men of the London and Ireland. In Edinburgh the admirable teaching of Cullen had raised the medical faculty to a height of prosperity of which his successor, James Gregory (1758–1821), was not unworthy. His nephew, William Cullen (1750–1810), was also well known and more widely known. These great teachers maintained in the northern university a continuous tradition of successful teaching, which the difference in academic and other conditions rendered hardly possible in London. Not was the northern school wanting in scientific investigators, such as John Abercrombie (1780–1844), known for his work on diseases of the brain and spinal cord, published in 1828, and many others. Turning to Ireland, it should be said that the Dublin school in this period produced two physicians of the highest distinction. Robert James Graves (1796–1853) was a most eminent clinical teacher and observer, whose lectures are regarded as the
model of clinical teaching, and indeed served as such to the most popular teacher of the Paris school in the middle of the century, Trouseau. William Stokes (1804-1878) was especially known for his works on diseases of the chest and of the heart, and for his clinical teaching.

German Medicine from 1800 to 1840.—Of the other countries of Europe, it is now only necessary to mention Germany. Here the chief home of positive medicine was still for a long time Vienna, where the “new Vienna school” continued and surpassed the glory of the old. Joseph Skoda (1805-1881) extended, and in some respects corrected, the art of auscultation as left by Laennec. Karl Rokitansky (1804-1878), by his colossal labours, placed the science of morbid anatomy on a permanent basis, and enriched it by numerous discoveries of detail. Most of the ardent cultivators of this science in Germany in the next generation were his pupils. In the other German schools, though some great names might be found, as Moritz Heinrich Romberg (1795-1873), the founder of the modern era in the study of nervous diseases, the general spirit was scholastic and the result barren till the teaching of one man, whom the modern German physicians generally regard as the regenerator of scientific medicine in Germany, made itself felt. Johann Lucas Schönlein (1793-1864) was first professor at Würzburg, afterwards at Zürich, and for twenty years at Berlin (from 1839-1859). Schönlein’s positive contributions to medical science were not large; but he made in 1839 one discovery, apparently small, but in reality most suggestive, namely, that the contagious disease of the head called favus is produced by the growth in the hair of a parasitic fungus. In this may be found the germ of the startling modern discoveries in parasitic diseases. His systematic doctrines founded the so-called “natural history school”; but his real merit was that of the founder or introducer of a method. In the words of H. Häser: Schönlein has the incontestable merit of having been the first to establish in Germany the exact method of the French and the English, and to impregnate this method with the vivifying spirit of German research.”

(J. F. P.)

Modern Progress.—In recent times the positive bent of modern knowledge and methods in other spheres of science and thought, and especially in biology, has influenced medicine profoundly. Minuter accuracy of observation was inculcated by the labours and teaching of the great anatomists of the 17th century; and, for modern times, experimental physiology was instituted by Harvey, anatomy having done little to interpret life in its dynamic aspects. For medicine in England Harvey did what William Gilbert did for physics and Robert Boyle for chemistry: he insisted upon direct interrogation of natural processes, and thereby annihilated the ascendency of mere authority, which, while nations were in the making, was an essential part of the machinery of those days. The welding together of heterogeneous and turbulent peoples. The degradation of medicine between Galen and Harvey, if in part it consisted in the blind following of the authority of the former physician, was primarily due to other causes; and its new development was not due to the discovery of the experimental method alone: social and political causes also are concerned in the advance even of the exact sciences. Among such contributory causes is the more familiar intercourse of settled nations which we enjoy in our own day; the ideas of one nation rapidly permeate neighbouring nations, and by the means of printed books penetrate into remoter provinces and into distant lands. Hence the description of the advance of medicine in western Europe and America may for the latest stage be taken as a whole, without that separate treatment, nation by nation, which in the history of earlier times was necessitated.

In the leading place, the credit must be given to the new development of science. The several influences of modern Germany, France and America became of the first importance to English medicine; but these tides, instead of pursuing their courses as independent streams, have become confluent. The work of Theodor Schwann (1810-1882), Johannes Müller (1809-1875), Rudolph Virchow and Karl Ludwig (1816-1895) in Germany, of R. T. H. Laennec and Claude Bernard in France, was accepted in England, as that of Matthew Baillie, Charles Boll, Bright, Graves and others of the British school, quickly made itself felt abroad.

The character of modern medicine cannot be summed in a word, as with more or less aptness, that of some previous periods may be. Modern medicine, like modern science, is as boldly speculative as it has been in any age, and yet it is as observant as in any naturalistic period; its success lies in the addition to these qualities of the method of verification; the fault of previous times being not the activity of the speculative faculty, without which no science can be fertile, but the lack of methodical reference of all and sundry propositions, and parts of propositions, to the test of experiment. In no department is the experimental method more continually justified than in that of the natural history of disease, which at first sight would seem to have a certain independence of it and a somewhat exclusive value of its own. Hippocrates had no opportunity of verification by necropsy, and Sydenham ignored pathology; yet the clinical features of many but recently described diseases, such, for example, as that named after Graves, and myxoedema, both associated with perversions of the thyroid gland, lay as open to the eye of physicians in the past as to our own. Again, to the naturalist the symptoms of tabes dorsalis were distinctive enough, had he noted them. No aid to the trained eye was necessary for such observations, and for many other such; yet, if we take Sir Thomas Watson (1792-1882) as a modern Sydenham, we may find in his lectures no suspicion that there may be a palsy of muscular co-ordination apart from deprivation of strength. Indeed, it does not seem to have occurred to any one to compare the muscular strength in the various kinds of paraplegia. Thus it was, partly because the habit of acceptance of authority, waning but far from extinguished, dictated to the clinical observer what he should see; partly because the eye of the clinical observer lacked that special training which the habit and influence of experimental verification alone can give, that physicians, even acute and practised physicians, failed to see many and many a symptomatic series which went through its evolutions conspicuously enough, and needed for its appreciation no unknown aids or methods of research, nor any further advances of pathology. We see now that the practice of the experimental method endows with a new vision both the experimenters themselves and, through his influence, those who are associated with him in medical science, even if these be not themselves actually engaged in experiment; a new discipline is imposed upon old faculties, as is seen as well in other sciences as in those on which medicine more directly depends. And it is not only the perceptions of eye or ear which tell, but also the association of concepts behind these adits of the mind. It was the concepts derived from the experimental methods of Harvey, Lavoisier, Liebig, Claude Bernard, Helmholtz, Darwin, Pasteur, Lister and others which, directly or indirectly, trained the eyes of clinicians to observe more closely and accurately; and not of clinicians only, but also of pathologists, such as Matthew Baillie, Cruveilhier, Kokitsansky, Bright, Virchow—to name but a few of those who, with (as must be admitted) new facilities for necropsies, began to pile upon us discoveries in morbid anatomy and pathology. If at first in the 18th century, and in the earlier 19th, the discoveries in this branch of medical knowledge had a certain isolation, due perhaps to the prepossessions of the school of Sydenham, they soon became the property of the physician, and were brought into co-ordination with the clinical phenomena of disease. The great Morgagni, the founder of morbid anatomy, himself set the example of this study coupled with clinical observation; and always insisted that the clinical story of the case should be brought side by side with the revelations of the necropsy. In pathology, indeed, Virchow’s (1821-1902) influence in the transfiguration of this branch of science may almost be compared to that of Darwin and Pasteur in their respective domains.

In the last quarter of the 19th century the conception grew clearer that morbid anatomy for the most part demonstrates
over many lives, the terms of which at first sight had seemed wholly disparate. Thus, for example, as generations succeed one another, nervous disorders appear in various guise: epilepsy, megrim, insanity, asthma, hysteria, neurasthenia, a motley array at first sight, seemed to reveal themselves as terms of a morbid series; not only so, but certain disorders of other systems also might be members of the series, such as certain diseases of the skin, and even peculiar susceptibilities or immunities in respect of infections from without. On the other hand, not a few disorders proved to be alien to classes to which narrower views of causation had referred them; of such are tases dorsalis, neuritis, infantile palsy or tetanus, now removed from the category of primary nervous diseases and placed in one or other of the class of infections; or, conversely, certain forms of disease of the joints are now regarded with some certainty as members of more than one series of diseases chiefly manifest in the nervous system. In the effects of simpler poisons the recognition of unity in diversity, as in the affiliation of a peripheral neuritis to arsenic, illustrated more definitely this serial or etiological method of classifying diseases. On the other hand, inheritance was dismissed, or survived only as a "susceptibility" in cases of such research expediency, and some other maladies were recognized as infections which in their first stages, it was seen to consist in a translation of the infectious element from parent to offspring. These new conceptions of the multiplicity in unity of disease, and of the fluidity and continuity of morbid processes, might have led to vagueness and over-baldness in speculation and reconstruction, had not the experimental method been at hand with clues and tests for the several series. Of this method the rise and wonderful extension of the science of bacteriology also furnished no inconsiderable part.

In the disease of the scalp called favus, Schönlein had discovered a minute mycelial fungus; a remarkable discovery, for it was the first conspicuous step in the attribution of diseases to the action of minute parasites. Schönlein thus did something to introduce new and positive conceptions and exacter methods into Germany; but unfortunately his own mind retained the abstract habit of his country, and his abilities were dissipated in the mere speculations of Schelling. Similarly Karl Hoffmann of Wiirzburg wasted his precocious and audacious talent of the medical student in the types of abstruse pathology, yet in an inchoate stage, and of embryology, illuminated and enlarged biological conceptions, both normal and abnormal; and the ens revolu subistens in corpore disappeared forever—at any rate from physiology and medicine. Before Darwin—if the name of Darwin may be used to signify the transformation of thought of which he was the chief artificer—natural objects were regarded, not in medicine and pathology only, as a set of hidebound events; and natural operations as moving in fixed grooves, after a fashion which it is now difficult for us to realize. With the melting of the ice the more daring spirits dashed into the new current with such ardour that for them all traditions, all institutions, were thrown into hotchpot; even elderly and sober physicians took enough of the infection to liberate their minds, and, in the field of the several diseases and in that of post-mortem pathology, the hollowness of classification by superficial resemblance, the transitoriness of forms, and the flow of processes, broke upon the view. Thus it came about not only that classifications of disease based on superficial likeness—such as jaundice, dropsy, inflammation—were broken up and their parts redistributed, but also that even more set diseases began to lose their settlements, and were recognized as terms of series, as transitory or culminating phases of perturbations which might be traced to their origins, and in their earlier stages perhaps withstood.

The doctrine of heredity in disease thus took a larger aspect; the view of morbid series was no longer bounded even by the life of the individual; and the propagation of taints, and of morbid varieties of man, from generation to generation proved to be no mere repetition of fixed features but, even more frequently, to be modes of development or of dissolution betraying themselves often in widely dissimilar forms, in series often extending...
views opened by the discoveries of Pasteur on the side of pathogeny, and of J. F. Cohnheim (1825-1884) and of Illya Metchnikoff on the dynamical side of histology. Of the older ontological notions of disease the strongest were those of the essence of fever and of the essence of inflammation. Broussais had done much to destroy the notion of fever as an entity, but by extravagances in other directions he had discredited the value of his main propositions. Yet, although, as Andral and other French physicians proved, it was extravagant to say that all fevers take their origin from some local inflammation, it was true and most useful to insist, as Broussais vehemently insisted, that "fever" is no substance, but a generalization drawn from symptoms common to many and various diseases springing from many various and often local causes; from causes agreeing perhaps only in the factor of elevation of the temperature of the body. To the establishment of this new concept the improvement and general use of the clinical thermometer gave invaluable advantages. This instrument, now indispensable in our daily work at the bedside, had indeed long been known both to physiologists (Hallier) and to clinicians. In the 18th century A. de Haët, and, in the United Kingdom, George Cleggorn (1716-1780) of Dublin and James Currie (1756-1805), carried on the use of the thermometer in fevers; and on the continent of Europe in later years F. G. von Bärensprung (1822-1866) and Ludwig Traube (1818-1876) did the same service; but it is to the work of Karl August Wunderlich (1815-1877) that we owe the establishment of this means of precision as a method of regular observation both in pathology and in clinical medicine. By his almost exhaustive comparison of febrile movements as symptomatic processes Wunderlich dealt the last blow to the prevailing doctrine of the "entity" of "fever"; while, on the clinical side Brodie and Louis, in 1826-1872, by their careful clinical and pathological studies of forms of fever, relieved the new doctrine of the extravagances of Broussais, and prepared the way for the important distinction of enteric from typhus fever by A. P. Stewart (1813-1883), William Jenner, William Budd (1811-1880), Charles Murchison (1830-1879), J. H. F. Autenrieth (1772-1835), Heinrich Gustav Magnus (1802-1870), Huss and others. By the learned and accomplished Armand Trusseau British and German influences were carried into France.

Meanwhile Cohnheim and Metchnikoff were engaged in destroying the ontological conception not of fever only, but also of inflammation, of which, as a local event, an ontological conception was long held, so like the uterineovesical affections the migration of the white corpuscles of the blood Cohnheim, on the bases laid by Virchow, brought the processes of inflammation within the scope of the normal, seeing in them but a modification of normal processes under perturbations of relatively external incidence; even the formation of abscesses was thus brought by him within the limits of perversion of processes not differing essentially from those of health; and "new formations," "plastic exudations," and other discontinuous origins of an "essential" pathology, fell into oblivion. And it is not alien from the present point of view to turn for a moment to the light thrown on the cardio-arterial pulse and the measurement of its motions by the more intimate researches into the phenomena of the circulation by many observers, among whom in the 19th century James Hope, E. J. Marey (1830-1904) and C. F. W. Ludwig will always take a leading place. By them the demonstration of Harvey that the circulation of the blood is in large part a mechanical process, and nowhere independent of mechanical laws, was considerably enlarged and extended. In particular the fluctuations of the pulse in fevers and inflammations were better understood, and accurately registered; and we can scarcely realize now that before Harvey the time of the pulse seems not to have been counted by the watch. Discovery in these various directions then led physicians to regard fever and inflammation not as separable entities, but as fluctuating symptom-groups, due to swervings of function from the normal balance under contingent forces.

As to such reforms in our conceptions of disease the advances of bacteriology profoundly contributed, so under the stress of consequent discoveries, almost prodigious in their extent and revolutionary effect, the conceptions of the etiology of disease underwent no less a transformation than the conceptions of disease itself. It is proper to point out here how intimately a pathology thus regenerated modified current conceptions of disease, in the linking of disease to oscillations of health, and the regarding many diseases as modifications of the normal set up by the impingement of external causes; not a few of which indeed may be generated within the body itself—"autogenetic poisoning." The appreciation of such modifications, and of the working of such causes, has been facilitated greatly by the light thrown upon normal processes by advances in physiology; so dependent is each branch of knowledge upon the advances of contiguous and incident studies. To biological chemistry we have been deeply indebted during the latter half of the 19th century. In 1872, Hoppe-Seyler (1825-1892) gave a new beginning to our knowledge of the chemistry of secretion and of excretion; and later students have increased the range of physiological and pathological chemistry by investigations not only into the several stages of albuminoid material and the transitions which all food-stuffs undergo in digestion, but even into the structure of proteoplasm itself. Digestion, regarded not long ago as little more than a trituration and "coction" of ingesta to fit them for absorption and transfer them to the tissues, now appears as an elaboration of peptones and kindred intermediate products which, so far from being always bland, and mere bricks and mortar for repair or fuel for combustion, pass through phases of change during which they become so unfit for assimilation as to be positively poisonous. The formation of prussic acid at a certain period of the vital processes of certain plants may be given as an example of such phases; and poisons akin to muscarin seem to arise frequently in development or regression, both in animals and plants. Thus the digestive function, in its largest sense, is now seen to consist, not only in preparation and supply, but in no small measure also of protective and antidotal conversions of the matters submitted to it; coincidently with agents of digestion proper are found in the circuit of normal digestion "anti-substances" which neutralize or convert peptones in their poisonous phases; an autochthonous ferment, such as rennet for instance, calling forth an anti-rennet, and so on. Now as our own bodies thus manipulate substances poisonous and antidotal, if in every hour of our lives we were concerned with the various intruding organisms, whose processes of digestion are as dangerous as our own; if these destructive agents, which no doubt are incessantly gaining admission to our bodies, do not meet within us each its appropriate compensatory defensive agent, dissolution will begin. Thus, much of infection and immunity are proving to be but special cases of digestion, and teleological conceptions of protective processes are modified.

Under the name of chemotaxis (W. Pfeffer) are designated certain of the regulative adaptations by which such ends are attained. By chemical warnings the defensive processes seem to be awakened, or summoned; and when we think of the infinite variety of such possible phases, and of the multitude of corresponding defensive agents, we may form some dim notion of the complexity of the animal blood and tissues, and within them of the organic molecules. Even in normal circumstances their play and countplay, attractive and repellent, must be manifold almost beyond conception; for the body may be regarded as a collective organization consisting of a huge colony of micro-organisms become capable of a common life by common and mutual arrangement and differentiation of function, and by toleration and utilization of each other's peculiar products; some organs, such as the liver, for example, being credited with a special power of neutralizing poisons, whether generated under normal conditions or under abnormal, which gain entrance from the intestinal tract. As a part of these discoveries has arisen another but kindred doctrine
that of hormones (Starling), juices prepared, not for excretion, not even for partial excretion, but for the fulfilment of physiological equilibration. As the reciprocities of the various organs, maintained throughout the divisions of physiological labour, is not merely a mechanical stability; it is also a mutuo-equilibration in functions incessantly at work on chemical levels, and on those levels of still higher complexity which seem to rise as far beyond chemistry as chemistry beyond physics. Not only are the secreted juices of specialized cells thus set one against another in the body, whereby the various organs of the body maintain a mutual play, but the blood itself also in its cellular and fluid parts contains elements potent in the destruction of bacteria and of their secretions. Thus endowed, the blood, unless overwhelmed by extraordinary invasions, does not fail in stability and self-purification. So various are the conditions of self-regulation in various animals, both in respect of their peculiar and several modes of assimilating different foods, and of protecting themselves against particular dangers from without; that, as we might have expected, the bloods taken from different species, or even perhaps from different individuals, are found to be so divergent that the healthy serum of one species may be, and often is, poisonous to another; not so much in respect of adventitious substances, as because the phases of physiological change in different species do not harmonize; each by its peculiar needs has been modified until, in their several conditions of life, they vary so much about the mean as to have become almost if not quite alien one to another.

In the preservation of immunity then, in its various degrees and kinds, not only is the chemistry of the blood to be studied, but also its histology. By his eminent labours in cellular pathology, Virchow, and Metchnikoff later, gave the last blow to the mere humoral pathology which, after an almost unchallenged prevalence for some two thousand years, now finds a resting-place only in our nurseries. Now the cellular pathology of the blood, investigated by the aid of modern staining methods, is as important as that. The study of immunity to clinical poisons—indeed, apart from research, no practitioner at this day—can dispense with examination of the blood for purposes of diagnosis; its coagulability and the kinds and the variations of the cells it contains being evidence of many definitely morbid states of the body. Again, not only in certain diseases may strange cells be found in the blood (e.g. in myelogenic leucæma), but parasites also, both in man, as those of malaria, of sleeping sickness, of kala-azar, and in animals, as redwater, yellow fever, n’gana have been discovered, to the great advantage of preventive medicine. For some of these, as redwater (pyrosoma), antidotes are already found; for others, as for yellow fever—of which the parasite is unknown, but the mode of its transmission, by the mosquito, discovered (Finlay-Reed)—preventive measures are reducing the prevalence.

It is obvious that the results of such advances prescribe for the clinical physician methods which cannot be pursued without assistance; a physician engaged in busy practice cannot himself undertake even the verifications required in the conduct of individual cases. Skill in modern laboratory work is as far out of the reach of the untaught as performance on a musical instrument. In spite, therefore, of the encyclopaedic tradition which has persisted from Aristotle through the Arab and medieval schools down to Herbert Spencer, it is forced upon us in our own day that in a pursuit so manysided as medicine, whether in its scientific or in its practical aspect, we have to submit more and more to that division of labour which has been a condition of advance in all other walks of life. It is now fully recognized that diseases of infants and children, of the insane, of the generative organs of women, of the larynx, of the eye, have been brought successively into the light of modern knowledge by 'specialists,' and by them distributed to the profession; and that in no other way could this end have been attained. That the division of labour, which may seem to disintegrate the calling of the physician, really unites it, is well seen in the clinical laboratories which were initiated in the later 19th century, and which are destined to a great future. By the approach of skilled pathologists to the clinical wards, a link is forged between practitioners and the men of science who pursue pathology disinterestedly. The first clinical laboratory seems to have been that of Von Ziemssen (1829-1902) at Munich, founded in 1885; and, although his example has not yet been followed as it ought to have been, enough has been done in this way, at Johns Hopkins University and elsewhere, to prove the vital importance of the system to the progress of modern medicine. At the same time provision must be made for the integration of knowledge as well as for the winning of it by several adits. A conspicuous example of the incalculable evil wrought by lack of integration is well seen in the radical divorce of surgery from medicine, which is one of the most mischievous legacies of the middle ages—one whose mischief is scarcely yet fully recognized, and yet which is so deeply rooted in our institutions, in the United Kingdom at any rate, as to be hard to obliterate. That the methods and the subject matter of surgery and of medicine are substantially the same, and that the advance of one is the advancement of the other, the division being purely artificial and founded merely on accidents of personal bent and skill, must be insisted upon at this time of our history. The distinction was never a scientific one, even in the sense in which the word science can be used of the middle ages; it originated in social conceits and in the contempt for mechanical arts which came of the cultivation of 'ideas' as opposed to converse with 'matter,' and which, in the dawn of modern methods, led to the derision of Boyle by Oxford humanists as one given up to 'base and mechanical pursuits.' Had physicians been brought into contact with facts as hard as those faced by the surgeons of the 16th century (cf. Ambrose Paré), their art would not have lain so long in degradation. It is under this closer occupation with mechanical conditions that surgery to-day is said—not without excuse, but with no more than superficial truth—to have made more progress than medicine. Medicine and surgery are but two aspects of a whole: Preventive surgery (we must regard medicine and when Lister, his disciple, penetrated into the secrets of wound fevers and septicæma, he illuminated surgery and medicine alike, and, in the one sphere as in the other, co-operated in the destruction of the idea of "essential fevers" and of inflammation as an "entity." Together, then, with the necessary multiplicity of specialism, one of the chief lessons of the latter moiety of the 19th century was the unity of medicine in all its branches—a unity strengthened rather than weakened by special researches, such as those into "medical" and "surgical" pathology, which are daily making more manifest the absurdity of the distinction. Surgeons, physicians, oculists, laryngologists, gynaecologists, neurologists and the rest, all are working in allotments of the same field, and combining to a common harvest.

While pathology then, which is especially the "science of medicine," was winning territory on one side from physiology, of which it is in a sense the other, on the other hand, by making ground of its own in the post mortem room and museum of morbid anatomy, and was fusing these gains in the laboratory so as to claim for itself, as a special branch of science by virtue of peculiar concepts, its due place and provision—provision in the establishment of chairs and of special laboratories for its chemical and biological subdivisions—clinical medicine, by the formal provision of disciplinary classes, was illustrating the truth of the experience that teaching and research must go hand-in-hand, the one reinforcing the other: that no teacher can be efficient unless he be engaged in research also; nay, that for the most part even the investigator needs the encouragement of disciples. Yet it was scarcely until the last quarter of the 19th century that the apprenticeship system, which was a mere initiation into the art and mystery of a craft, was recognized as antiquated and, in its virtual exclusion of academic study, even mischievous. In place of it, systematic clinical classes have become part of the scheme of every efficient school of medicine. A condition of this reform was the need of a preliminary training of the mind of the pupil in pure science, even in physics and chemistry; that is to say, before introduction
into his professional studies. The founding of new teaching universities, in which England, and even France, had been at some disadvantage as compared with Scotland and Germany, strengthened the movement in favour of enlarging and liberalizing technical training, and of anticipating technical instruction by some broader scientific discipline; though, as in all times of transition, something was lost temporarily by a departure from the old discipline of the grammar school before a new scheme of training the mind in scientific habits and conceptions was established or fully apprehended. Yet on the whole, even from the beginning, the revolt was useful in that it shook the position of the "learned physician," who took a literary, fastidious and meditative rather than an experimental interest in his profession, and, as in great part a descendant of the humanists, was never in full sympathy with experimental science. At the risk no doubt of some defects of culture, the newer education cleared the way for a more positive temper, awoke a new sense of accuracy and of verification, and created a skeptical attitude towards all conventions, whether of argument or of practice. Among the drawbacks of this temper, which on the whole made for progress, was the rise of a school of excessive scepticism, which, forgetting the value of the accumulated stores of empiricism, despised those degrees of moral certainty that, in so complex a study and so tentative a practice as medicine, must be our portion for the present, and even for a long future, however great the triumphs of medicine may become. This scepticism took form in the school, most active between 1860 and 1880, known as the school of "Expectant Medicine." These teachers, genuinely touched with a sense of the scantiness of our knowledge, of our confidence in abstract terms, of the insecurity of our alleged "facts," case-histories and observations, alienated from traditional dogmatism and disgusted by meddlesome polypharmacy—enlightened, moreover, by the issue of cases treated by means such as the homeopathic, which were practically "expectant"—urged that the only course open to the physician, duly conscious of his own ignorance and of the mystery of nature, is to put his patient under diet and nursing, and, relying on the tendency of all equilibriums to recover themselves under perturbation, to await events (Vis medicatrix naturae). Those physicians who had occupied themselves in the study of the exact sciences, or more closely or more exclusively of the wreckage of the post mortem room, were the strongest men of this school, whether in England or abroad.

But to sit down helpless before human suffering is an undeniable attitude. Moreover, the insight into origins, into initial morbid processes revealed by the pathologists, awoke more and more the hope of dealing with the elements of disease, with its first beginnings; and in the field of therapeutics, chemical and biological experiment, as in the case of digitalis, mercury and the iodides, was rapidly simplifying remedies and defining their virtues, so that these agents could be used at the bedside with more precision. Furthermore, the aversion from drugging had the advantage of directing men's minds to remedies taken from the region of the physical forces, of electricity (G. B. Duchenne, 1806-1875), of gymnastics (Ling, 1776-1839), of hydrotherapy (V. Priessnitz), of massage (Weir Mitchell), of climate (James Clarke), of diet (R. B. Todd, King Chambers, &c.), and even of hypnotherapy (James Braid 1795-1860), while with the improvement of the means of locomotion came the renewal of the old faith and the establishment of new methods in the use of mineral springs. These and such means, often in combination, took much of the place formerly given to the use of drugs.

Again, like spirit dictated the use of the physical or "natural" means on a larger scale in the field of prevention.

Hygiene. From the new regard given by physiologists and pathologists to the study of origins, and in the new hopes of thus dealing with disease at its springs, not in individuals only but in cities and nations, issued the great school of Preventive Medicine, initiated in England—E. A. Parkes (1819-1876), J. Simon, Sir B. W. Richardson (1828-1896), Sir H. W. Acland (1815-1900), Sir G. Buchanan (1831-1895), and forwarded in Germany by Max von Pettenkofer (1818-1901). Hygiene became for pathology what "milieu" is for physiology. By the modification of physical conditions on a national scale a prodigious advance was made in the art of preventing disease. The ghastly roll of infantile mortality was quickly purged of its darkest features (Ballard and others); aided by bacteriology, sanitary measures attained some considerable degree of exactness; public medicine gained such an ascendancy that special training and diplomas were offered at universities; and in 1875 a consolidated act was passed for the United Kingdom establishing medical officers of health, and responsible lay sanitary authorities, with no inconsiderable powers of enforcing the means of public health in rural, urban, port and other jurisdictions, with summary methods of procedure. A department of public health was formed within the precincts of the Local Government Board; government laboratories were established, and machinery was devised for the notification of infectious diseases. The enormous growth of towns during the second half of the 19th century was thus attended with comparative safety to these great aggregates of mankind; and the death-rates, so far from being increased, relatively decreased in substantial proportions. In 1878 an act was passed giving like powers in the case of the infectious diseases of animals. The establishment in England of the Register of qualified practitioners and of the General Medical Council (in 1858) did something, however imperfectly, to give unity to the profession, unhappily bisected by "the two colleges," and did much to organize, to strengthen and to purify medical education and qualification. In 1876 women were admitted to the Register kept by the Council. In 1871 the Anatomical Act of 1832 was amended; and in 1876 the Vivisection Act was passed, a measure which investigators engaged in the medical sciences of physiology and pathology regarded as likely to prevent in England the advance of knowledge of living function, both in its normal balance and in its perturbations, and moreover to slacken that habit of incessant reference of propositions to verification which is as necessary to the clinical observer as to the experimentalist. However the opinion of later generations may stand in respect of the Vivisection Act, it will surely appear to them that the other acts, largely based upon the results of experimental methods, strengthening and consolidating the medical profession, and fortifying the advance of medical education, led directly to a fundamental change in the circumstances of the people in respect of health. The intelligent classes have become far better educated in the laws of health, and less disposed to quackery; the less intelligent are better cared for and protected by municipal and central authority. Thus the housing of the poor has been improved, though this difficult problem is yet far from solution; not the large towns only, but the larger villages also, are cleansed and drained; food has been submitted to inspection by skilled officers; water supplies have been undertaken on a vast scale; personal cleanliness has been encouraged, and with wonderful success efforts have been made to bring civilized Europe back from the effects of a long wave of Oriental asceticism, which in its neglect and contempt of the body led men to regard filth even as a virtue, to its pristine cleanliness under the Greeks and Romans. During the latter half of the 19th century the death-rate of many towns was reduced by something like 50%. Some plagues, such as typhus fever, have been dispersed; others, such as enteric fever, have been almost banished from large areas; and there is much reason to hope that cholera and plague, if introduced, could not get a footing in western Europe, or in any case could be combated on scientific principles, and greatly reduced. Temperance in the use of alcohol has followed the demonstration not of its harmfulness as a food or tonic, but also of its harmfulness, save in very small quantities. In the earlier part of the 19th century, and in remote districts even in its later years, the use of alcohol was regarded not as a mere indulgence, but as essential to health; the example of teetotalers, as seen in private life and in the returns of the insurance offices, has undermined this prepossession. From the time of Plato medicine has been accused of ministering to the service of unholy persons, and to
in our knowledge of more or less local diseases, we may begin with the nervous system. It is in this department, from its abstruse-ness and complexity, that we should expect the application of anatomy, physiology, and therapeutics to yield important results. It is here, too, that the physician has the greatest difficulty in determining whether a patient is suffering from organic disease, or from morbid—to be most delayed. If we consult the medical works even of the middle of the 19th century we shall find that, in the light of the present time, accurate knowledge in this sphere, whether clinical, pathological or therapeutic, could scarcely be said to exist. Even in the hands of J. A. Lockhart Clarke (1817-1880), one of the earliest investigators of nervous pathology, the improvement of the compound microscope had not attained the achromatism, the penetration and the magnification which have since enabled J. L. C. Schroeder-van der Kolk (1797-1862), Albert von Kölliker, Santiago Ramon y Cajal, C. Golgi (b. 1844) and others to reveal the minute anatomy of the nervous centres; while the discrimination of tissues and morbid products by stains, as in the silver and osmic acid methods, and in those known by the names of Carl Weigert or Marchi, had scarcely begun. In England the Hospital for the Paralysed and Epileptic was founded in 1859, where Charles E. Brown-Séquard (1817-1894), J. Hughlings-Jackson, Thomas Bzzard, Benjamin Breuer (1795-1873), Pierre Bretonneau (1806-1875), Hermann von Recklinghausen (1813-1894), Daniel Defere (b. 1843) found an adequate field for the clinical and pathological parts of their work. In France, in the wards of the Hôtel Dieu, Guillaume Benjamin Duchenne (1806-1875), in association with Trouseau and in his private clinic, pursued his memorable clinical and therapeutical researches into the diseases of the nervous system; and Jean M. Charcot (1825-1893) in that great asylum for the wreckage of humanity—the Salpêtrière—discovered an unworked mine of chronic nervous disease. M. H. Romberg (1795-1875) and Theodor Meynert (1833-1892) also were pioneers in the study of nervous diseases, but it was not till later in the century that Germany took a high place in this department of medicine. The discoveries of the separate paths of sensory and motor impulses in the spinal cord, and consequently of the laws of reflex action, by Charles Bell and Marshall Hall respectively, in their illumination of the phenomena of nervous function, may be compared with the discovery in the region of the vascular system of the circulation of the blood; for therein a key to large classes of normal and aberrant functions and a fertile principle of interpretation were obtained. Nor was the theory of reflex action confined to the more "mechanical" functions. By G. H. Lewes and others the doctrine of "cerebral reflex" was suggested, whereby actions, at first achieved only by incessant attention, became organized as conscious or subconscious habits; as for instance in the playing on musical or other instruments, when acts even of a very elaborate kind may directly follow the impulses of sensations, conscious adaptation and the deliberate choice of means being thus economized. This law has important ethical and political bearings; but in the province of disease this advance of what may be compared to the interlocking of points and signals has had wide influence not only in altering our conceptions of disease, but also in enlarging our views of all perturbations of function. The grouping of reflex "units," and the paths wherein impulses travel and become associated, have been made out by the physiologist (Sherrington and others) working on the healthy animal, as well as by the record of disease; and not of spontaneous disease alone, for the artificial institution of morbid processes in animals has led to many of these discoveries, as in the method of A. V. Waller (1816-1870), who tracked the line of nervous strands by experimental sections, and showed that when particular strands are cut off from their nutritive centres the consequent degeneration follows the line of the separated strands. By similar methods nature, unassisted, betrays herself but too often; in many instances—probably originating primarily in the nervous tissues themselves—the course of disease is observed to follow certain paths with remarkable consistency, as for instance in diseases of particular tracts of the spinal cord. In such cases the paths of degeneration are so neatly defined that, when the tissues are prepared after death by modern methods, they are plainly to be seen running along certain columns, the subdivisions

When, leaving the infections, we look for evidence of progress in the propagation of children. But bodily defect is largely a result of evil circumstances, in the prevention of which the physician is not unsuccessfully engaged, and the growth of sympathy means a stronger cement of the social structure. At any rate the mean standard of health will be raised, perhaps enormously.

In the tropics, as well as in Europe, such methods and such researches threw new light upon the causes and paths of the terrible infections of these climates. In 1865, two years before Koch discovered the bacillus of tubercle, C. L. A. Laveran (b. 1845) discovered the parasite of malaria, and truly conceived its relation to the disease; thus within two years were made two discoveries either of which was sufficient to make the honour of a century. Before the end of the 19th century this discovery of the blood parasite of malaria was crowned by the hypothesis of Patrick Manson, proved by Ronald Ross, that malaria is propagated by a certain genus of gnat, which acts as an intermediate host of the parasite. Cholera (Haffkine) and yellow fever are yielding up their secrets, and falling under some control. The 20th century, by means of this illumination of one of the darkest regions of disease, may diminish human suffering enormously. By habits of the habitation of rich and beautiful regions of the earth's surface now, so far as man's work is concerned, condemned to sterility. Moreover, freedom of trade and of travel has been promoted by a reform of the antiquated, cumbersome, and too often futile methods of quarantine—a reform as yet very far from complete, but founded upon a better understanding of the nature and propagation of disease.

Special Departments.—Hitherto we have presented a survey of the progress of the science and practice of medicine on general lines; it remains to give some indication of the advance of these subjects of study and practice in particular departments. As regards infections, it is not to be supposed that our knowledge of these maladies has been advanced by pathology and bacteriology only. In the clinical field also it has received a large enlargement. Diphtheria, long no doubt a plague among mankind, was not carefully described until by Pierre Bretonneau in 1826; and since his time our conception of this disease has been extended by the study of later, secondary and incidental phases of it, such as neuritis, which had always formed part of the diphtheritic series, though the connexion had not been detected. Influenza, again, was well known to us in 1836-1840, yet clinical observers had not traced out those sequelae which, in the form of neuritis and mental disorder, have impressed upon our minds the persistent virulence of this infection, and the manifold forms of its activity. By the discovery of the bacillus of tubercle, the physician has been enabled to piece together a long and varied list of maladies under several names, such as scrofula and lupus, many of them long suspected to be tuberculous, but now known to belong to the series. It is on clinical grounds that beriberi, scarlet fever, measles, &c., are recognized as belonging to the same class, and evolving in phases which differ not in intimate nature but in the more superficial and inessential characters of time, rate and polymorphism; and the impression is gaining strength that acute rheumatism belongs to the group of the infections, certain sore throats, chorea and other apparently distinct maladies being terms of this series. Thus the field of disease arising not from essential defect in the body, but from external contingencies, is vastly enlarging; while on the other hand the great variability of individuals in susceptibility explains the very variable results of such extrinsic causes. Coincidently therewith, the hope of neutralizing infections by fortifying individual immunity has grown brighter, for it appears that immunity is not a very radical character, but one which, as in the case of vaccination, admits of modification and accurate adjustment in the individual, in no long time and by no very tedious methods. Evidence is accumulating which may end in the explanation and perhaps in the prevention of the direst of human woes—cancer itself, though at present inquiry is being directed rather to intrinsic than to extrinsic causes.
of which in the normal state may hardly be distinguishable one from another: some run in strips along the periphery of the spinal cord, at its anterior, middle or posterior segments, as the case may be; in other cases such strips occur within its substance, whether along columns of cells or of white matter. It is needless to point out how such paths of disease, in their association with characteristic symptoms, have illuminated the clinical features of disease as well as the processes of normal function.

Not, however, all diseases of the nervous system conduct themselves on these definite paths, for some of them pay no attention to the geography of structure, but, as one may say, blunder indiscriminately among the several parts; others, again, pick out particular parts definitely enough, but not parts immediately continuous, or even contiguous. Diseases of the latter kind are especially interesting, as in them we see that parts of the nervous structure, separated in space, may nevertheless be associated in function; for instance, wasting of a group of muscles associated in function may depend on a set of central degenerations occurring in parts whose connexion, in spite of dissociation in space, we thus perceive. The indiscriminating diseases, on the other hand, we suspect not to be primarily of nervous origin, but to depend rather on the agency of other constituent tissues of this system, as, of the blood-vessels or the connective elements. Thus, arguing inversely, we may learn something of the respective natures of these influences and of the way in which the nervous system is affected secondarily.

Yet even the distribution of toxic matters by the blood is not necessarily followed by general and indiscriminate injury to the nervous elements. In infantile palsy, for example, and in tabes dorsalis, there is good reason to believe that, as definitely as the traces of the disease are found in certain physiologically distinct nervous elements, they are due nevertheless to toxic agents arriving by way of the blood. Here we enter upon one of the most interesting chapters of disorders and modes of disorder of this and of other systems. It has come out more and more clearly of late years that poisons do not betray even an approximately indifferent affinity for all tissues, which indeed a little reflection would tell us to be a priori improbable, but that each tends to fix itself to this cell group or to that, picking out parts for which they severally have affinities. Chemical, physiological and pathological research is exploring the secret of these more refined kinds of "anchorage" of molecules. In 1868 Drs A. Crum Brown and T. R. Fraser proved that by substitution of molecules in certain compounds a stimulant could be converted into a sedative action; thus by the addition of the methyl group CH₃ to the molecule of adrenaline, the former medicine, or brucine, the tetanizing action of these drugs is converted into a paralyzing action. The number of these instances, and the variety of them, are now known to be very large; and it is supposed that what is true of these simpler agents is true also of far more elaborate phases of vital metabolism. Now, what is remarkable in these and many other reactions is not only that effects apparently very opposite may result from minute differences of molecular construction, but also that, whatever the construction, agents, not wholly indifferent to the body or part, tend to anchor themselves to organic molecules in some way akin to them. Highly complex as are all animal tissues, or nearly all, yet in this category of high complexity are degrees higher and higher again of which we can form little conception, so elaborate are they, so peculiar in their respective properties, and probably so fugitive. It is this which underlies the difficulty of appreciating the range of known physical and chemical molecules which excites our wonder; and a reflection of these peculiar properties is seen in their affinities for this or that toxic or constructive agent, whereby the peculiarity, for example, of a particular kind of nerve cell may be altered, antagonized, reinforced or converted. On the other hand, the reagents by which such modifications are apt to be produced are not necessarily simple; many of them likewise are known to be of very high degrees of complexity, approaching perhaps in complexity the molecules to which they are akin. Of such probably are the toxins and antitoxins of certain infections, which, anchoring themselves not by any means indiscriminately, but to particular and concerted molecules, by such anchorage antagonize them or turn them to favourable or unfavourable issues. Toxins may thus become so closely key into their corresponding atom group, as for instance in tetanus, that they are no longer free to combine with the anti-toxin; or, again, an anti-toxin injected before a toxin may anticipate it and, preventing its mischievous adhesion, dismiss it for excetration. In the mutual behaviour of such cells, toxins, and antitoxins, and again of microbes themselves, we may demonstrate even on the field of the microscope the modes of such actions, which seem to partake in great measure at any rate of a chemical quality (agglutinins, coagulins, chemotaxis).

It is convenient here to add that such reactions and modifications, if more conspicuous in the nervous system, are of course not confined to it, but are concerned in their degree in all the processes of metabolism, being most readily traced by us in the blood.

Many other diseases formerly regarded as primarily diseases of the nervous system are not such; but, by means of agents either introduced into the body or modified there, establish themselves after the affinities of these in contiguous associated parts of the structure, as in vascular, membranous or connective elements, or again in distant and peripheral parts; the perturbations of nervous function being secondary and consequential.

Of such are tetanus and diphtheria, now known to be due to the establishment from without of a local microbial infection, from which focus a toxin is diffused to the nervous matter. The terrible nervous sequels of some forms of inflammation of the membranes of the brain, again, are due primarily to microbial invasion rather than of their nervous contents; and many other diseases may be added to this list. The grave palsy in such diseases as influenza, diphtheria, beriberi, or ensuing on the absorption of lead, are in the main not central, but due to a symmetrical peripheral neuritis.

Among diseases not primarily nervous, but exhibited in certain phenomena of nervous disorder, are diseases of the blood-vessels. Much light has been thrown upon the variations of arterial and venous blood pressures by Karl Ludwig von Recklinghausen (1856-1895) and his many followers: by them not only the diseases of the circulatory system itself are elucidated, but also those of other systems—the nervous, for instance—which depend intimately on the mechanical integrity of the circulation of the blood as well as on the chemical integrity of the blood itself.

With changes of the pressures of the blood in arteries, veins or capillaries, and in the heart itself, and its respective chambers, static changes are apt to follow in these parts; such as degeneration of the coats of the arteries, due either to the silent tooth of time, to persistent high blood pressures, or to the action of poisons such as lead or syphilis. Syphilitic lesion of the arteries, and likewise of other fibrous tissues, often involves grave consequential damage to nervous structures fed or supported by such parts. Some of the most successful of the advances of medicine as a healing art have followed the detection of syphilitic disease of the vessels, or of the supporting tissues of nervous centres and of the peripheral nerves; so that, by specific medication, the treatment of paralytic, convulsive, and other terrible manifestations of nervous disease thus secondarily induced is now undertaken in early stages with definite prospect of cure.

Individual Forms of Disease.
of not dissimilar character, whereby a vessel is blocked not by a travelling particle, but by a clotting of the blood in situ, probably on the occasion of some harm to the epithelial lining of the vessel. Such injuries are apt to occur in sphyllitic endarteritis, or senile arterial decay, whereby an artery may be blocked permanently, as if with an embolus, and the area supplied by it, in so far as it was dependent upon this vessel, deprived of nutrition. These events, although far more mischievous in the brain, the functions of which are far-reaching, and the collateral circulation of which is ill-provided, are seen very commonly in other parts.

It is in the structure of the brain itself that modern research has attained the most remarkable success. In 1861 an alleged "centre" of speech was detected, by a combination of clinical and pathological researches, by Paul Broca (1824-1880). By these means also, in the hands of Hughlings-Jackson, and more conclusively by experimental research initiated by G. T. Fritsch (b. 1838) and T. E. Hitzig (b. 1838), but pursued independently and far more systematically and thoroughly by David Ferrier (b. 1843) and his disciples, it was proved that the cerebrum is occupied by many such centres or exchanges, which preside over the formulation of sensations into purposive groups of motions—kinesthesis of H. Charlton Bastian (b. 1837). The results of these experimental researches by means of electrodes inserted in the nerve elements of brain have revolutionised our conceptions of cerebral physiology, and thrown a flood of light on the diseases of the brain. Not only so, but this mapping of the brain in areas of function now often enables the clinical physician to determine the position of disease; in a certain few cases of tumour or abscess, so precisely that he may be enabled to open the skull above the part affected and to extirpate it—operations which are surely a triumph of science and technical skill (Lister, W. MacEwen, V. Horsley).

The remarkable discovery of the dual nature of the nervous system, of its duplex development as a lower and upper system of "neurons," has shed much light upon the problems of practical medicine, but this construction is described under Brain; Neuropathology; Muscle and Nerve, &c.

In mental diseases little of first-rate importance has been done. The chief work has been the detection of chronic changes in the cortex of the brain, by staining and other histological methods, in degenerative affections of this organ—Theodor Meynert (1833-1892), W. Griesinger (1817-1888), Bevan Lewis—and in the separation from insanity due to primary cerebral disease of the nerve elements of such diseases as general paralysis of the insane, which probably arise, as we have said, by the action of poisons on contiguous structures—such as blood-vessels and connective elements—and invade the nervous matter secondarily. Some infections, however, seem to attack the mental fabric directly; intrinsic toxic processes which may be suspected on the detection of neurin and cholin in the fluids of the brain (F. W. Mott). Truer conceptions of normal psychology have transformed for us those of the morbid—P. Pinel (1745-1826), Griesinger, Henry Maudsley (b. 1835), Mercier, Kräepelin, Rivers—and indicated more truly the relations of sanity to insanity. In the treatment of insanity little has been done but to complete the non-restraint system which in principle belongs to the earlier part of the 19th century (Pinel, Tuke, R. G. Hill, J. Conolly). An enormous accumulation of lunatics of all sorts and degrees seems to have paralysed public authorities, who, at vast expense in buildings, mass them more or less indiscriminately in barracks, and expect that their sordid and difficult disorders can be properly studied and treated by a medical superintendent charged with the whole domestic management of a few young patients under his eye. The life of these insane patients is as bright, and the treatment as humane, as a barrack life can be; but of science, whether in pathology or medicine, there can be little. A considerable step in advance is the establishment by the London County Council of a central laboratory for its asylums, with an eminent pathologist at its head: from this laboratory valuable reports are in course of issue. Provision for the reception and treatment of insanity in its earliest and more curable stages can scarcely be said to exist. Sufferers from mental disease are still regarded too much as troublesome persons to be hidden away in humane keeping, rather than as cases of manifold and obscure disease, to be studied and treated by the undivided attention of physicians of the highest skill. The care and education of idiots, initiated by Gugenbuhl and others, is making way in England, and if as yet insufficient, is good of its kind.

By the genius of René Théophile Laennec (1781-1826), diseases of the lungs and heart were laid on a foundation so broad that his successors have been occupied in detail and refinement rather than in reconstruction. In heart disease the chief work of the latter half of the 19th century was, in the first quarter, such clinical work as that of William Stokes and Peter More Latham (1789-1872); and in the second quarter the fuller comprehension of the vascular system, central and peripheral, with its cycles and variations of blood pressure, venous and arterial. Moreover, the intricacies of structure and function within the heart itself have been more fully discriminated (W. H. Gaskell, Aschoff, A. Keith, Wenkebach, J. Mackenzie). By the greater thoroughness of our knowledge of the physics of the circulation—Étienne Marey (b. 1830), Karl Ludwig (1816-1895), Leonard Hill—we have attained to a clearer conception of such events as arterial embolism, and, by further research, physiological and pathological phlogistogists have defined more precisely the virtues of curative drugs. To the discovery of the parts played in disease by thrombosis and embolism we have referred above. With this broader and more accurate knowledge of the conditions of the health of the circulation a corresponding efficiency has been gained in the manipulation of certain remedies and new methods of treatment of heart diseases, especially by baths and exercises.

As regards pulmonary disease, pneumonia has passed more and more definitely into the category of the infections: the modes of invasion of the lungs and pleura by tuberculosis has been more and more accurately followed; and the treatment of these diseases, in the spheres br. th. of prevention and of cure, has undergone a radical change. Instead of the close protection from the outer air, the respirators, and the fancy diets of our fathers, the modern politorinaire camps out in the open air in all weathers, is fed with solid food, and in his exercise and otherwise is ruled with minute particularity according to the indications of the clinical thermometer and other symptoms. The almost reckless reliance on climate, which, at Davos for instance, marked the transition from the older to the modern methods, has of late been sobered and supplemeted by more systematic attention to all that concerns the mode of life of the invalid. The result is that, both in physicians and in the public, a more hopeful attitude in respect of the cure of phthisis has led to a more earnest grappling with the infection in its earliest stages and in every phase, with a correspondingly large improvement in prevention and treatment. Indeed, in such early stages, and in patients who are enabled to command the means of an expensive method of cure, phthisis is no longer regarded as desperate; while steps are being taken to provide for those who of their own means are unable to obtain these advantages, by the erection of special sanatoriums on a more or less charitable basis. Perhaps no advance in medicine has done so much as the study of tuberculosis to educate the public in the methods and value of research in medical subjects, for the results, and even the methods, of such labours have been brought home not only to patients and their friends, but also to the farmer, the dairyman, the butcher, the public carrier, and, indeed, to every home in the land.

In the management of neurites that the aid of surgical means has become eminent in inward disease. In the treatment of effusions into the pleura and, though with less advantage, of pericardial effusions, direct mechanical interference was practised by one physician and another, till these means of attaining rapid and complete cure took their places as indispensable, and were extended from thoracic diseases to those of the abdominal and other inner parts formerly beyond the reach of direct therapeutics. Lord Lister's discoveries brought these new methods to bear with a certainty and a celerity previously undreamed of; and many visceral maladies, such as visceral ulcers, disease of the pancreas,
stone of the kidney or gall-bladder, perityphilitis, ovarian dropsey, which in the earlier part of the 19th century were either fatal or crippling, are now taken promptly and safely in hand, and dealt with successfully. Even for internal cancer cure or substantial relief is not infrequently obtained. We have said that this advance is often quoted, not very wisely, to signify that in modern progress "medicine" has fallen behind surgery—as if the art of the physician were not one and indivisible. That certain Fellows of the College of Physicians (especially in gynaecology) have personally taken operative procedures in hand is some good omen that in time the unreal and mischievous schism between medicine and surgery may be bridged over.

In the department of abdominal disease progress has been made, not only in this enormous extension of means of cure by operative methods, but also in the verification of diagnosis. The first recognition of a disease may be at a necropsy, but then usually by irresponsible pathologists; it is another matter when the physician himself comes under rebuke for failing to seize a way to cure, while the chance remained to him, by section of the abdomen during life. The abdomen is still "full of surprises"; and he who has most experience of this deceptive region will have least confidence in expressing positive opinions in particular cases of disease without operative investigation. Besides the attainments mentioned above, in respect of operative progress, many important revisions of older rule-of-thumb knowledge have come about, and not a few other substantial discoveries. Among the revisions may be added some addition to our knowledge of dyspepsia, attained by analytic investigations into the contents of the stomach at various stages of digestion, and by examining the passage of opaque substances through the primæ wæ by the Röntgen rays. Thus the defects, whether of this secretion or of that, and again of motor activity, the state of the valvular junctions, the volume of the cavities, and their position in the abdomen, may be ascertained, and dealt with as far as may be; so that, although the fluctuations of chemical digestion are still very obscure, the application of remedies after a mere traditional routine is no longer excusable. In our conceptions of the later stages of assimilation and of excretion, with the generation of poisons (auto-intoxication) in the intestinal tract, there is still much obscurity and much guess-work; yet in some directions positive knowledge has been gained, partly by the physiologist, partly by the physician himself. Of such are the better understanding of the functions of the liver in normal catabolism, in the neutralization of poisons absorbed from the intestines or elsewhere, in the causation of jaundice, and in diabetes [Bernhardt Naunyn (b. 1839) and F. W. Pavy]. Nor must we forget the unfoldung of a new chapter of disease, in the nosology of the pancreas. In diabetes this organ seems to play a part which is not yet precisely determined; and one fell disease at least has been traced to a violent access of inflammation of this organ, caused perhaps by entry of foreign matters into its duct. The part of the pancreas in digestion also is better understood. The part of the spleen in the motley group of dyspepsias and anaemias, conspicuous as it often is, still remains very enigmatic.

The peritoneum is no longer regarded with awe as inviolable; by modern methods, if not as manageable as other lympthic sacs, it is at any rate accessible enough without considerable risk to life. Not only in its bacteriological relations are the conditions of peritonitis recognized in its various kinds, but also the state known as "shock" turns out to be quasi-mechanical, and avoidable by measures belonging in considerable part to this category. Thus, by the avoidance both of toxæmia and of shock, peritonitis and other dangers of the abdomen, such as strangulations or intussusceptions of the bowels, formerly desperate, can in many cases be dealt with safely and effectively.

The knowledge of diseases of the kidneys has made no great advance since the time of Richard Bright. In the sphere of physiology and in the interpretation of associated arterial diseases much obscurity still remains; as, for instance, concerning the nature of the toxic substances which produce those bilateral changes in the kidneys which we call Bright's disease, and bring about the "uraemia" which is characteristic of it. Lardaceous disease, however, here and in other regions, now appears to be due to the specific toxins of pyogenic micro-organisms. In stone of the kidney a great advance has been made in treatment by operative means, and the formation of these stones seems to recent observers to depend less upon constitutional bent (gout) than upon unhealthy local conditions of the passages, which in their turn again may be due to the action of microorganisms.

To Thomas Addison's descriptions of certain anaemias, and of the disease of the suprarenal capsules which bears his name, something has been added; and W. Hunter's researches on the severer anaemias are doing much to elucidate these subtle maladies. And on the influence of these inconspicuous bodies and of the pituitary body in sustaining arterial blood pressures physiologists have thrown some important light.

The secret of the terrible puerperal sepsicaemia was read by J. F. Semmelweiss (q.v.), wherein he proved himself to be the greatest of Lister's predecessors (see Lister). The diseases peculiar to women (see Gynaecology) have received attention from early times, but little progress had been made in their interpretation till the 19th century. In the middle part of the century, by a natural exaggeration of the importance of newly-discovered local changes in the pelvic organs, much harm was done to women by too narrow an attention to the site, characters and treatment of these; the middle-someness of the physician becoming in the temperament of woman a morbid obsession. To James Matthews Duncan (1826-1890) we chiefly owe a saner and broader comprehension of the relative importance of the local and the general conditions which enter into the causation of uterine and ovarian disorders. In operations for diseases of the pelvis, ovarian dropsey, cancer of the uterus, and other grave diseases of the region, success has been stumpy.

The subject of diseases of the skin much has been done, in the minuter observation of their forms, in the description of forms previously unrecognized, and in respect of bacterial and other causation and of treatment. The comparison of observations in various climates and peoples has had some weight; while in the better knowledge of their causes their treatment has found permanent advantage. Not only is the influence of bacteria in the causation of many of them newly revealed, but it is now recognized also that, even in skin diseases not initiated by microbic action, microbes play a considerable and often a determining part in their perpetuation; and that the rules of modern aseptic surgery are applicable with no little success to skin therapeutics. We have learned that "constitutional" causes play a smaller part in them than was supposed, that a large number of diseases of the skin, even if initiated by general disorder, are or soon become local diseases, being, if not initiated by local infection yet perpetuated thereby, so that, generally speaking, they are to be regarded by linear pathology.

The diseases of children have not lacked the renewed attention, the successful investigation, and the valuable new lights which have been given to other departments of medicine. That infantile paralysis is an infection, and that its unhappy sequels are now treated with more hope of restoration, has been indicated already. Infantile diarrhoea has also been recognized as a common infection (Ballard), and the means of its avoidance and cure ascertained. The conditions of diet and digestion in children are now far better understood, and many of their maladies, formerly regarded as organic or incomprehensible, are cured or prevented by dietetic rules. Rickets, scurvy and "marasmus" may be instanced as diet diseases in children. Acute inflammation of the ear, with its alarming extensions to the cerebral cavity, is now dealt with successfully by surgical means, and infected abscesses or even encephalitic abscesses are reached and cleaned. The origins, kinds and processes of meningitis are more clearly distinguished, and referred each to its proper cause—for the most part bacterial.

As by the discovery of stethoscopy by Laennec a new field of medical science and art was opened up, so, more recently, inventions of other new methods of investigation in medicine
have opened to us other fields of little less interest and importance. Of such is the ophthalmoscope, invented by H. von Helmholtz in 1852. By the revelations of this instrument not only have the diseases of the eye been illuminated, but much light has been thrown also upon the part of the eye in more general maladies; as, for instance, in syphilis, in diabetes, in kidney diseases, and in diseases of the brain—F. C. Donders (1818-1886), Alfred von Gräfe (1830-1889) and others. A remarkable help to the cure of headaches and wider nervous disorders has come out of the better appreciation and correction of errors of refraction in the eye. Radiography has done great things for surgery; for medicine its services are already appreciable, and may prove more and more valuable hereafter. In 1879 the use of the spectroscope in medicine was pointed out by Dr Charles A. MacMunn (b. 1852). By E. du Bois-Reymond, Robert Remak (1815-1863), Carlo Matteucci (1811-1868), Guillaume Duchenne (1806-1875), the value of electricity in medicine, greater in diagnosis perhaps than in therapeutics, was demonstrated. By the sphygmograph (E. J. Marey, 1863) attention was drawn to the physical features of the circulation, to the signs of degeneration of the arterial tree and less definitely to the fluctuations of blood pressure; but as we have said under the consideration of diseases of the heart, the kymographs of Ludwig and his pupils brought out these fluctuations far more accurately and completely. By these and other instruments of precision, such as the thermometer, of which we have already spoken, the eminent scientific discipline of the measurement of functional movements, so difficult in the complex science of biology, has been cultivated. By the laryngoscope, invented about 1850 by Manuel Garcia the celebrated singing-master, and perfected by Johann Czermak (1828-1873) and others, the diseases of the larynx also have been brought into the general light which has been shed on all fields of disease; and many of them, previously known more or less empirically, submitted to precise definition and cure. Of such we may cite tuberculosis of the larynx, formerly as incurable as distemming; and "adenoids"—a disease revealed by intrascopic methods—which used grievously to thwart and still the growth both of mind and body in children, are now promptly removed, to the infinite advantage of the rising generation. To the value of stains in clinical diagnosis, especially in investigation of perversions of the blood in many maladies, we have already made some reference. The discovery of the Röntgen rays has also extended the physician's power of vision, as in cases of aortic aneurysm, and other thoracic diseases.

By photography and diagrammatic records the clinical work of hospital wards has been brought into some better definition, and teaching made more accurate and more impressive. The separation of the alkaloids belongs rather to the earlier part of the 19th century, but the administration of these more accurate medications by means of hypodermic injection (see Therapeutics) belongs to the latter. The ancient practice of transfusion has been placed on a more intelligible footing, and by the method of saline injections made more manageable as a means of correcting disturbances. In the tale of medicine the work of William Farr, Karl Pearson, and others has been brought into line with other scientific methods: the method is a difficult one, and one full of pitfalls for the unwary, yet when by co-operation of physician and mathematician its applications have been perfected its services will appear more and more indispensable.

Among the achievements of the medicine of the 19th century the growth of the medical press must not be forgotten. In England, by the boldness of the Lancet (founded in 1823), the tyranny of prescription, inveterate custom, and privilege abused was defied and broken down; freedom of learning was regained, and promotion thrown open to the competent, independently of family, gild and professional status. For the record and diffusion of rapidly growing knowledge, learned societies, universities and laboratories, greatly increased in number and activity, issue their transactions in various fields; and by means of yearbooks and central news-sheets the accumulation of knowledge is organized and made accessible.

It is interesting to find that, with all this activity in the present reformed methods of research and verification are not confined to the work of the passing day; in the brilliant achievements of modern research and reconstruction the maxim that "Truth is the daughter of Time" has not been forgotten. In the field of the History of Medicine the work of scholars such as Francis Adams of Banchory (1796-1861), William A. Greenhill (1814-1894) and C. Creighton in England, Maximilien P. Littre (1801-1881) and Charles V. Darmereb (1817-1872) in France, and Heinrich Häser (1811-1888) and August Hirsch, Diels, Weltmann and Julius Pagel in Germany, will prove to our children that tradition was as safe in our hands as progress itself.

(T. C. A.)

MEDINA, JOSE TORIBIO (1852— ), Chilean bibliographer, was born at Santiago, and was educated for the bar. His first publication, when a very young man, was a metrical translation of Longfellow's Evangeline. When twenty-two he was appointed secretary to the legation at Lima. After his return he published a history of Chilean literature (1878), and a work upon the aboriginal tribes (1884). In this latter year he was appointed secretary of legation in Spain, and availed himself of the opportunity of examining the treasures of the old Spanish libraries. These researches, repeated on subsequent visits to Spain, and also to France and England, enriched him with a mass of historical and bibliographical material. Among his publications may be mentioned the Biblioteca hispano-americana, a catalogue of all books and pamphlets relating to Spanish America printed in the last four centuries. Bibliotheca hispano-chilensis, a similar work, commenced in 1877; the standard and magnificent history of printing in the La Plata countries (1892); comprehensive works on the Inquisition in Chile, Peru and the Philippines; and the standard treatise on South American medals (1890). In addition, Señor Medina produced the fullest bibliographies yet attainable of books printed at Lima, Mexico and Manila, and a number of memoirs and other minor writings. No other man had rendered anything like the same amount of service to the literary history and bibliography of the Spanish colonies.

MEDINA, or rather AL-MEDINA (the city), or MEDINAT RASUL ALLAH (the city of the apostle of God), a town of the Hejaz in Arabia, about 830 m. by rail S.S.E. of Damascus, in 25° N., 40° E.; the refuge of Mahomet on his emigration from Mecca, and a renowned place of Meoscope pilgrimage, consecrated by the possession of his tomb. The name Medina goes back to the Koran (sur. xxxiii, 60); the old name was Yathrib, the Lathrippa of Polley and the Lathripa of Stenchantus by Byzantium.

Medina stands in a basin at the northern extremity of an elevated plain, on the western skirt of the mountain range which divides the Red Sea coast-lands from the central plateau of Arabia. At an hour's distance to the north it is dominated by Mount Ohod, an outlying spur of the great mountains, the scene of the well-known battle (see MÁHOMÉT), and the site of the tomb and mosque of the Prophet's uncle Hamza. To the east the plain is bounded by a long line of hills eight or ten hours distant, over which the Nejd road runs. A number of torrent courses (of which Wadi Kanat to the north, at the foot of Mount Ohod, and W. Aikik, some miles to the south, are the most important) descend from the mountains, and converge in the neighbourhood of the town to unite farther west at a place called Zaghba, whence they descend to the sea through the "mountains of the Téhama"—the rough country between Medina and its

1 This is a very rough estimate. The road from Yambu on the Red Sea, which runs some ten miles north of east, is by: Ed. Breton's estimate 132 m. From Medina to Mecca by the inland or high road he makes 248 m. The usual road near the coast by Rabigh and Khulas and thence to W. Fatima cannot be very different in length. Caravans traverse it in about ten or eleven days.
port of Yambu—under the name of W. Idam. Southwards from Medina the plain extends unbroken, but with a slight rise, as far as the eye can reach. The convergence of torrent-courses in the neighbourhood of Medina makes this one of the best-watered spots in northern Arabia. The city lies close to one of the great volcanic centres of the peninsula, which was in violent eruption as late as AD. 1266, when the lava stream approached within an hour’s distance of the walls, and dammed up W. Kanat. The result of this and other prehistoric eruptions has been to confuse the underground water, so important in Arabian tillage, which can be reached at any point of the oasis by sinking deep wells. Many of the wells are brackish, and the natural fertility of the volcanic soil is in many places impaired by the salt with which it is impregnated; but the date-palm grows well everywhere, and the groves, interspersed with gardens and cornfields, which surround the city on all sides except the west, have been famous from the time of the Prophet. Thus situated, Medina was original seat of the city, and the groves and gardens of merchants; nor, apart from the indispensable trade in provisions, has it ever acquired commercial importance like that which Mecca owes to the pilgrimage. Landowners and cultivators are still a chief element in the population of the city and suburbs. The townspeople proper, on the other hand, are a very motley race. New settlers remain behind with each pilgrimage; attracted by the many offices of profit connected with the mosque, the stipends paid by the sultan to every inhabitant, and the gains to be derived by pilgrim-cicerones (Museumweirs) or by those who make it a business to say prayers at the Prophet’s mosque for persons who send a fee from a distance, as well as the alms which the citizens are accustomed to collect when they go abroad, especially in Turkey. The population of the city and suburbs may be from 50,000 to 80,000.

The city proper is surrounded by a solid stone wall, with towers and four massive gateways of good architecture, forming an irregular oval running to a kind of angle at the north-west, where stands the castle, held by a Turkish garrison. The houses are good stone buildings similar in style to those of Mecca; the streets are narrow but clean, and in part paved. There is a copious supply of water conducted from a tepid source (ez-Zarkä) at the village of Kuba, 2 m. south, and distributed in underground cisterns in each quarter. The glory of Medina, and the only important building, is the mosque of the Prophet, in the eastern part of the city, a spacious enclosed court between 400 and 500 ft. in length from north to south, and two-thirds as much in breadth. The minarets and the lofty dome above the sacred graves are imposing features; but the circuit is hemmed in by houses and narrow lanes, and is not remarkable except for the principal gate (Bal al-Salam) at the southern end of the west front, facing the sacred graves, which is richly inlaid with marbles and fine tiles, and adorned with golden inscriptions. This gate leads into a deep portico, with ten rows of pillars, running along the southern wall. Near the farther end of the portico, but not adjoining the walls, is a sort of doorless house or chamber hung with rich curtains, which is supposed to contain the graves of Mahomet, Abu Bekr and Omar. To the north of this is a smaller chamber of the same kind, draped in black, which is said to represent the tomb of Fatima. Both are enclosed with an iron railing, so closely interwoven with brass wire-work that a glimpse of the so-called tombs can only be got through certain apertures, where intercessory prayer is addressed to the prophet, and pious salutations are paid to the other saints. The portico in front of the railing is not ineffective, at least by nightlight. It is paved with marble, and in the eastern part with mosaic, laid with rich carpets; the southern wall is clothed with marble pierced with windows of good stained glass, and the great railing has a striking aspect; but an air of tawdriness is imparted by the vulgar painting of the columns, especially in the space between the tomb and the pulpit, which has received, in accordance with a tradition of the Prophet, the nickname of the Garden of the Ladies (Idam). It was decorated with barbaric attempts to carry out this idea in colour? The throng of visitors passing along the south wall from the Bab al-Salam to salute the tombs is separated from the Garden by an iron railing. The other three sides of the interior court have porticoes of less depth and mean aspect, with three or four rows of pillars. Within the court are the well of the Prophet, and some palm-trees said to have been planted by Fatima; this “grove” is separated from the rest of the court by a wooden partition.

The original mosque was a low building of brick, roofed with palm-branches, and much smaller than the present structure. The wooden pulpit from which Mahomet preached appears to have stood on the same place with the present pulpit in the middle of the south portico. The dwelling of the Prophet and the huts of his women adjoined the mosque. Mahomet died in the hut of Ayesha and was buried where he died; Abu Bekr and Omar were afterwards buried with him. In A.D. 732 the mosque, which had previously been enlarged by Omar and Othman, was entirely reconstructed on a grander scale and in Byzantine style by Greek and Coptic artisans at the command of the caliph Walid and under the direction of Ibn Abd-al-Aziz. The enlarged plan included the huts above named, which were pulled down. Thus the place of the Prophet’s burial was brought within the mosque; but the recorded discontent of the city at this step shows that the feeling which regards the tomb as the great glory of the mosque, and the pilgrimage to it as the most meritorious that can be undertaken except that to Mecca, was still quite unknown. It is not even certain what was done at this time to mark off the graves. Ibn ‘Abd Rabih, in the beginning of the 10th century (Ikhâ, Cairo ed., iii. 366), describes the enclosure as a hexagonal wall, rising within three cubits of the ceiling of the portico, clothed in marble for more than a man’s height, and above that height daubed with the unguent called khulak. This may be supplemented from Isuktarih, who calls it a lofty house without a door. That there are no gravestones or visible tombs within is certain from what is recorded of occasions when the place was opened up for repairs. Ibn Jubair (p. 193 seq.) and Samhudi speak of a small casket adorned with silver, fixed in the eastern wall, which was supposed to be opposite the head of the Prophet, while a silver nail in the south wall indicated the point to which the corpse faced, and from which the salutation of worshippers was to be addressed (Burton misquotations). The European fable (mentioned and refuted, e.g. in Histoire des Arabes par l’abbé de Marigny, t. i. p. 46, Paris, 1750) of the coffin suspended by magnets is totally unknown to Moslem tradition. The smaller chamber of Fatima is comparatively modern. In the time of Ibn Jubair and of Ibn Batuta (unless the space between the railing and the tomb is seldom entered except by the servants of the mosque. It contains the treasures of the mosque in jewels and plate, which were once very considerable, but have now dwindled, last of all by the Waghûhins in the beginning of the 19th century. The word rauda also means a mausoleum, and is applied by Ibn Jubair to the tomb itself. Thus the tradition that the space between the pulpit and the tomb was called by the Prophet one of the gardens of Paradise probably arose from a mistake.
MEDINA—MEDINA SIDONIA, DUKE OF

the latter, as is so often the case, is merely copying his predecessor) there was only a small marble trough north of the raud (or grave) which “is said to be the house of Fatima or her grave, but God only knows.” It is more probable that Fatima was buried in the Bakī, where her tomb was also shown in the 12th century (Ibn Jubair, pp. 198 seq.).

The mosque was again extended by the caliph Mahdi (A.D. 781) and was burned down in 1256. Of its appearance before the fire we have two authentic accounts by Ibn ‘Abd Rabbih early in the 10th century, and by Ibn Jubair, who visited it in 1184. The old mosque had a much finer and more regular appearance than the present one; the interior walls were richly adorned with marble and mosaic arabesques of trees and the like, and the outer walls with stone marquetry; the pillars of the south portico (seventeen in each row) were in white plaster with gilt capitals, the other pillars were of marble. Ibn ‘Abd Rabbih speaks of eighteen gates, of which in Ibn Jubair’s time, as at present, all but four were walled up. There were then three miaretes. After the fire which took place just at the time of the fall of the caliphate, the mosque long lay in a miserable condition. Its repair was chiefly due to the Egyptian sultans, especially to Kait Bey, whose restoration after a second fire in 1481 amounted almost to a complete reconstruction. Of the old building nothing seems to have remained but some of the columns and part of the walls. The miaretes have also been rebuilt and two new ones added. The great dome above the tomb, the railing round it, and the pulpit, all date from Kait Bey’s restoration.

The suburbs, which occupy as much space as the city proper, and are partly walled in, lie south-west of the town, from which they are separated by an open space, the halting-place of caravans. Through the suburbs runs the watercourse called Wadi Buthan, a tributary of W. Kanāt, which the Yanbu’ road crosses by a stone bridge. The suburbs are the quarter of the peasants. Thirty or forty families with their cattle occupy a single courtyard (ḥāsh), and form a kind of community often at feud with its neighbours. The several clans of Medina must have lived in much the same way at the time of the Prophet. The famous cemetery called Bakī’ el-Chadhd, the resting-place of a multitude of the “companions” of the Prophet, lies immediately to the west of the city. It once contained many monuments, the chief of which are described by Ibn Jubair. Burkehardt in 1815 found it a mere waste, but some of the mosques have since been rebuilt.

History.—The story of the Amalkeites in Yathrib and of their conquest by the Hebrews in the time of Moses is purely fabulous (see Nödeke, Über die Amalkeiter, 1864, p. 36). The oasis, when it first comes into the light of history, was held by Jews, among whom emigrants from Yemen afterwards settled. From the time of the emigration of Mahomet (A.D. 622) till the Omayyads removed the seat of empire from Medina to Damascus, the town springs into historic prominence as the capital of the new power that so rapidly changed the fate of the East. Its fall was not less rapid and complete, and since the battle of Harra and the sack of the city in 683 it has never regained political importance (see Caliphate, B. §§ 1, 2, &c.). Mahomet invested the country not with an expedition but with the desolation that of the Harra round Mecca; but this provision has never been observed with strictness. After the fall of the caliphs, who maintained a governor in Medina, the native amirs enjoyed a fluctuating measure of independence, interrupted by the aggressions of the sheriffs of Mecca, or controlled by an intermittent Egyptian protectorate. The Turks after the conquest of Egypt held Medina for a time with a firmer hand; but their rule grew weak, and was almost nominal long before the Wahhābīs took the city in 1804. A Turko-Egyptian force retook it in 1812, and the Turks now maintain a pasha with a military establishment, while the cadi and chief agha of the mosque (a eunuch) are sent from Constantinople. In later years the influence of the Turkish government has been much strengthened, an important factor in its consideration being the construction of the railway from Syria to the Hejaz. Railway communication between Damascus and Medina was effected in 1908.

Authorities.—Medina has been described from personal observation by Burkehardt, who visited it in 1815, and Burton, who made the pilgrimage in 1853. Sa’di’s journey from Katif to Yambu’ (1819) was not allowed to enter the holy city. Burkehardt was permitted to walk barefoot on the Haram, and to take off his shoes with his usual thoroughness. Little is added to our information by the report of ‘Abd al-Razzīq, who performed the pilgrimage in 1878, on a medical commission from the English government. The valuable authorities are the description of Ibn ‘Abd Rabbih and Ibn Jubair is Samhūdī, of whose history Wūstenfeld published an abstract in the Göttingen Abhandlungen, vol. ix. (1861). It goes down to the end of the 15th century. The topography of the country about Medina is interesting both historically and geographically; Bākri, Yāqūt, and other Arabic geographers, supply much material on this topic. Some good information concerning Medina is contained in the 2nd volume of Doughty’s Travels in Arabia Deserta.

MEDINA, a village of Orleans county, in north-west New York, U.S.A., about 40 m. N.E. of Buffalo, and on Oak Orchard Creek. Pop. (1900), 4710. (857 foreign-born; 1905, state census), 5144. (1910) 5693. It is served by the New York Central & Hudson River Railroad, by the New York & Ohio, and by the Erie Canal. On Oak Orchard Creek and near the city are electric power plants, at the Medina Falls and at a large storage dam (60 ft. high) for water power, built in 1902. In the neighbourhood are extensive apple, peach and pear orchards; and vegetables, especially beans, are grown. There are valuable quarries of Medina sandstone, a good building-, paving- and flag-stone, varying in colour from light grey to brownish red, readily shaped and split, and less likely than limestone to crack or than granite to wear slippery; it was first found at Medina in 1837. There was a saw-mill on the creek near here in 1805, but the place was little settled before 1824, and its growth was due to the Erie Canal. It was incorporated in 1832.

MEDINA SIONIA, DON ALONSO PEREZ DE GUZMAN EL BUENO, 7TH DUKE OF (1550-1615), the commander-in-chief of the Spanish Armada, was born on the 10th of September 1550. He was the son of Don Juan Clares de Guzman, eldest son of the 6th duke, and of his wife Dofia Leonor de Manrique de Zuñiga y Sotomayor. His father died in 1555, and Don Alonso became duke, and master of one of the greatest fortunes in Europe, on the death of his grandfather in 1559. The family of Guzman was originally lords of Abiadós, on the southern slope of the Picos de Europa in the hill country of Leon. The name is believed to be a contraction or corruption of Gundamaris, i.e. son of Gundamar. An early family tradition represents them as having come from Britain, and they may have descended from one of the Scandinavian invaders who attacked the north coast of Spain in the 10th century. It is in the 11th century that they first appear, and they grew great by the reconquest of the country from the Mahomedans. The branch to which the dukes of Medina Sidonia belonged was founded by Alonso Perez de Guzman (1256-1309), surnamed El Bueno, the good, in the sense of good at need, or stout-hearted. In 1296 he defended the town of Tarifa on behalf of Sancho IV., and when the besiegers threatened to murder one of his sons whom they held as a prisoner he did not surrender, and afterwards he was killed. He was rewarded by great grants of crown land. The duchy of Medina Sidonia, the oldest in Spain, was conferred by John II. in 1445 on one of his descendants, Juan Alonso de Guzman, count of Niebla. The addition “El Bueno” to the family name of Guzman was used by several of the house, which included many statesmen, generals and colonial viceroys.

The 7th duke was betrothed in 1565 to Ana de Silva y Mendoza, who was then four years of age, the daughter of the prince of Eboi. In 1572 when the duchess was a little more than ten years of age, the pope granted a dispensation for the consummation of the marriage. The scandal of the time, for which there appears to be no foundation, accused Philip II. of a love intrigue with the princess of Eboi. The unvarying and unmerited favour he showed the duke has been accounted for on the ground that he

1 The titles and grandeeship passed, in accordance with Castilian law, by marriage of a daughter and heiress in 1777, to the marquis of Villafraanca, and have since remained in that house.
took a paternal interest in the duchess. Don Alonso, though he bore the name of El Bueno, was a man of mean spirit. He made no serious effort to save his mother-in-law from the persecution she suffered at the hands of Philip II. His correspondence is full of whining complaints of poverty, and appeals to the king for pecuniary favours. In 1581 he was created a knight of the Golden Fleece, and was named captain-general of Lombardy. By pressing supplications to the king he got himself exempted on the ground of poverty and poor health. Yet when the marquess of Santa Cruz (q.v.) died, on the 5th of February 1588, Philip insisted on appointing him to the command of the Armada. He was chosen even before Santa Cruz was actually dead, and was forced to go in spite of his piteous declarations that he had neither experience nor capacity, and was always sick at sea. His conduct of the Armada justified his plea. He was even accused of showing want of personal courage, and was completely broken by the sufferings of the campaign, which turned his hair grey. The duke retained his post of "admiral of the ocean" and captain-general of Andalusia in spite of the contempt openly expressed for him by the whole nation. When an English and Dutch armament appeared off Cadiz in 1596 he slothfully and timidly retreated from his position, and was held up to ridicule by Cervantes in a sonnet. Yet the royal favour continued unabated even under the successor of Philip II. In 1606 the obstinacy and folly of the duke caused the loss of a squadron which was destroyed near Gibraltar by the Dutch. He died in 1615.

See Cesario Duro, La Armada invincible (Madrid, 1884), which gives numerous references to authorities.

**MEDINA SIDONIA,** or MEDINASIDONIA, a town of southern Spain, in the province of Cadiz, 21 m. by road E.S.E. of Cadiz. Pop. (1900), 11,040. Medina Sidonia is built on an isolated hill surrounded by a cultivated plain. It contains a fine Gothic church, several convents, and the ancestral palace of the dukes of Medina Sidonia. It has a small agricultural trade, chiefly in wheat, olives and oats.

Medina Sidonia has been identified by some with the Asido of Pliny, but this is uncertain. Under the Visigoths the place was erected into a bishopric (Assidonia), and attained some importance; in the beginning of the 8th century it was taken by Tariq. In the time of Idrisi (12th century) the province of Shadââna or Skidona included, among other towns, Seville and Carmona; later Arab geographers place Shadââna in the province of Seville.

**MECIOLANUM,** or MEDILIANUM (mod. Milan, q.v.), an ancient city of Italy, and the most important in Gallia Transpadana. Livy attributes its foundation to the Galli Insubes under Bellovesus after their defeat of the Etruscans, in the time of the older Tarquin. According to other authorities, the Etruscan city of Melpum which preceded it was destroyed in 356 B.C. Objects of the Bronze age have been found outside the city on the south. The name itself is Celtic. The Romans defeated the Insubes in 225-222 B.C., and stormed Mediolanum itself in the latter year. Its inhabitants rebelled some twenty years later in the Hannibalic War, but were defeated and finally reduced to obedience in 196 B.C. They probably acquired Latin rights in 89, and full civic rights in 49 B.C., as did those of the other towns of Gallia Transpadana. It was later on (out until the 4th century A.D.) to have become a colony. It acquired a certain amount of literary eminence, for we hear of youths going from Comum to Mediolanum to study. In Strabo's time it was on an equality with Verona, but smaller than Pavitum, but in the later times of the empire its importance increased. At the end of the 3rd century it became the seat of the governor of Aemilia and Liguria (which then included Gallia Transpadana also, thus consisting of the 9th and 11th regions of Augustus), and at the end of the 4th, of the governor of Liguria only, Aemilia having one of its own thenceforth. From Diocletian's time onwards the praefectus praetorio and the imperial vicar of Italy also had their seat here: and it became one of the principal mints of the empire. The emperors of the West resided at Mediolanum during the 4th century, until Honorius preferred Ravenna, and in 402 transferred his court there. Its importance, described in the poems of Ausonius, is demonstrated by its many inscriptions, and the interest and variety of its contents. In these the rarity of the mention of its chief magistrates is surprising; and it is not impossible that owing to its very importance the right of appointing them had been taken from it (as Mommsen thinks). The case of Ravenna is not dissimilar. The inscriptions indicate a strong Celtic character in the population. Procopius speaks of it as the first city of the West, after Rome, and says that when it was captured by the Goths in 539, 300,000 of the inhabitants were killed. It was an important centre of traffic, from which roads radiated in several directions—"as railways do to-day"—to Comum, to the foot of the Lacus Venetus (Lago Maggiore), to Novara and Vercellae, to Ticinum, to Laus Pompeia and thence to Placentia and Cremona, and to Bergomum. None of these roads had an individual name, so far as we know. To its secular power corresponds the independent position which its Church took in the time of St Ambrose (q.v.), bishop of Milan in 374-397, who founded the church which bears his name, and here baptized St Augustine in A.D. 387, and whose relics is still in its possession. There is an inscription here of 1138 noting the property of the bishopric for the slaughter of the people of Thessalonica. After his death the period of invasions begins; and Milan felt the power of the Huns under Attila (452), of the Heruli under Odacar (476) and of the Goths under Theodoric (493). When Belisarius was sent by Justinian to recover Italy, Datius, the archbishop of Milan, joined him, and the Goths were expelled from the city. But Uraia, nephew of Vitigis the Gothic king, subsequently assaulted and retook the town, after a brave resistance. Uraia destroyed the whole of Milan in 539; and hence it is said that this city, once so important a centre of Roman civilization, possesses so few remains of antiquity. Narses, in his campaigns against the Goths, had invited the Lombards to his aid. They came in a body under Albin, their king, in 568, and were soon masters of north Italy. They entered Milan in the next year, but Pavia became the Lombard capital.

Of Roman remains little is to be seen above ground, but a portico of sixteen Corinthian columns near S. Lorenzo, which may belong to the baths of Hercules, mentioned by Ausonius, or to the palace of Maximian. Close to the Torre del Carrobiio remains of an ancient bridge and (possibly) of the walls of Maximian were found: and many remains of ancient buildings, including a theatre, have been discovered below ground-level. The objects found are preserved in the archaeological museum in the Castello Sforzesco. (See Milan.)

See Th. Mommsen in Corp. inscript. Latin. (Berlin, 1883), v. 617 sqq. (with full bibliography); Notizie degli Scavi, passim. (T. As.)

**MEDITERRANEAN SEA.** The Mediterranean is all that remains of a great ocean which at an early geological epoch, before the formation of the Atlantic, encircled half the globe along a line of latitude. This ocean, already diminished in area, retreated after Oligocene times from the Iranian plateau, Turkestan, Asia Minor and the region of the north-west Alps. Next the plains of eastern Europe were lost, then the Aralo-Caspian region and Western Russia and finally the valley of the Danube. The "Mediterranean region," as a geographical unit, includes all this area; the Black Sea and the Sea of Marmora are within its submerged portion, and the climate of the whole is controlled by the oceanic influences of the Mediterranean Sea. Professor Suess, to whom the above description is due, finds that the Mediterranean forms no exception to the rule in affording no evidence of elevation or depression within historic times; but it is noteworthy that its present basin is remarkable in Europe for its volcanic and seismic activity. Submarine earthquakes are in some parts sufficiently frequent and violent as seriously to interfere with the working of telegraph cables. Suess divides the Mediterranean basin into four physical regions, which afford probably the best means of description: (1) The western Mediterranean, from Gibraltar to Malta and Sicily,
MEDITERRANEAN SEA

which gives a mean depth over all of 768 fathoms. The following table is due to Karsten:

<table>
<thead>
<tr>
<th>Region</th>
<th>Volume</th>
<th>Mean Depth</th>
</tr>
</thead>
<tbody>
<tr>
<td>Western Mediterranean</td>
<td>1,356,512</td>
<td>881</td>

</tbody>
</table>

Krümmel gives the total volume of the basin as 4,749,020 cubic kilometres or 1,019,400 cubic statute miles, and the mean depth as 782 fathoms. (See OCEAN.)

Meteorology.—As already stated, the “Mediterranean region” forms a distinct climatic unit, chiefly due to the form and position of the Mediterranean Sea. The prevailing winds in this region, which the sea traverses longitudinally, are westerly, but the sea itself causes the formation of bands of low barometric pressure, and the Black Sea to some extent, which are frequently developed, while in summer the region comes under the influence of the polar margin of the tropical high pressure belt. Hence the Mediterranean region is characterized one of winter rainfall and a distinct winter, and it increases eastwards to the south, and the amount of total annual fall increasing in the same direction. The climate becomes more continental in type from west to east, but there are great local irregularities—the elevated plateaus of Algeria and Spain observed on both sides, and delay and the rainy seasons: the rains set in earlier in the west than in the east, and the total fall is greater. Temperature varies greatly, the annual mean varying from 56° F. to 77° F. In the Adriatic the temperature of the water is less than in the Atlantic in the eastern Mediterranean, having an average of 10°–12° F., but in the east this increases to 36° and even 40°. Autumn is warmer than spring, especially in the coastal regions, and this is exaggerated in the eastern region by local land winds, which are very strong in the region. The continental climate is certainly worn in the Mediterranean and Spain, and are then put aside till October. Local winds form an important feature in nearly all the coast climates of the Mediterranean, especially in winter, where it is cloudy and rainy, the north wind coming in from the snow-cold hinterland. Cold dry winds, often of great violence, occur in the Rhone valley (the Mistral), in Istria, and Dalmatia (the Bora), and in the western Caucasus. In a north-west trade wind, the Maestra, occurs in the Adriatic, which considerably modifies the climate in the season; in the Adriatic it is usually accompanied by cloud and moisture, often by rain. In Sicily and southern Italy the Sirocco occurs at all seasons; it is a dry, dusty wind from south-east or south-west. The influence of the winter land winds from the Sahara. Similar winds are met with in Spain (the Leveche), but they reach their greatest development in the Simoons of Algeria, and Syria, and the Khamsin of Egypt.

Temperature.—The temperature of the Mediterranean, the average temperature of the Mediterranean, being about 70° F., is 70° F., and the bottom temperature in the eastern Mediterranean is 55° F.

Saliinity.—In the extreme west the salinity of the surface water is very high, being 36 per cent, and the salinity of the Mediterranean is 39° and upwards in the Levant. Observations of salinity in the depths of the Mediterranean are very deficient, but the average is probably between 35° and 36°. In the eastern basin of the Mediterranean, the salinity of the surface water, the salinity of the sea, is 38°, and in the Levant 35°. The salinity of the bottom water in the Mediterranean is 36°3.

Circulation.—There is little definite circulation of water within the Mediterranean itself. It is the currents joining it with the Atlantic and Black Sea, and the surface and bottom waters of these seas flow downwards to assist in making good the loss by evaporation at the surface of the Mediterranean, and in both cases the water makes its way outwards along the bottom of the channels, and, encountering currents, have very little of the flowing. Elsewhere local surface currents are developed, either drifts due to the direct action of the winds, or streams produced by wind action heaping water up against the land; but these nowhere rise to the dignity of a distinct current-system, although they are often sufficient to obliterate the feeble tidal action characteristic of the Mediterranean. Dr Natterer, the chemist of the “Pola” expeditions, has expressed the opinion that the poverty of the pelagic fauna is solely due to the want of circulation in the depths.
MEDIUM—MEDLAR

Deposit.—A great part of the bottom of the Mediterranean is covered with blue muds, frequently with a yellow upper layer containing a considerable proportion of carbonate of lime, chiefly shells of pelagic Foraminifera. In many parts, particularly in the eastern basin, a calcareous or silicious crust, from half an inch to three inches in thickness, is met with; and Natterer suggested that the formation of this crust may be due to the production of carbonate of ammonium where deposits containing organic matter are buried, and the carbonic acid decomposed and precipitated as carbonate of lime and other substances from the waters nearer the surface. This view, however, has not met with general acceptance.

(M. N. D.)

Medium, primarily a person through whom, as an intermediate, communication is deemed to be carried on between living men and spirits of the departed, according to the spiritual hypothesis; such a person is better termed sensitive or automatist. The phenomena of mediumship fall into two classes, (1) "physical phenomena" (q. v.) and (2) trance and automatic phenomena (utterances, script, &c.:); both these may be manifested by the same person, as in the case of D. D. Home and Stanton Moses, but are often independent.

I. No sufficient mass of observations is to hand to enable us to distinguish between the results of trickery or hallucination on the one hand, and genuine supernormal phenomena on the other; but the evidence for raps and lights is good; competent observers have witnessed supposed materializations and there is respectable evidence for movements of objects.

Mediumship in the modern sense of the term may be said to have originated with the Rochester rappings of 1848 (see SPIRITUALISM); but similar phenomena had been reported by such authors as Apollonius of Tyana; they figure frequently in the lives of the saints; and the magician in the lower stages of culture is in many respects a counterpart of the white medium. Among physical mediums who have attained celebrity may be mentioned D. D. Home (q. v.), Stanton Moses and Eusapia Palladino; the last has admittedly been fraudulent at times, but no deceit was ever proved of Home; Stanton Moses sat in a private apartment, and no suspicion of his good faith was ever aroused.

W. Stanton Moses (1839–1892) was a man of university education, a clergyman and a schoolmaster. In 1872 he became interested in spiritualism and soon began to manifest mediumistic phenomena, which continued for some ten years. These included, besides trance communications, raps, telekinesis, levitation, production of lights, perfumes and musical sounds, apports and materialized hands. But the conditions under which the experiments were tried were not sufficiently rigid to exclude the possibility of normal causes being at work; for no amount of evidence that the normal life is marked by no lapse from rectitude affords a presumption that uprightness will characterize states of secondary personality.

Eusapia Palladino has been observed by Sir O. Lodge, Professor Richet, F. W. H. Myers, and other eminent investigators; the first named reported that none of the phenomena in his presence went beyond what could be accomplished in a normal manner by a free and uncontrolled person; but he was convinced that movements were produced without apparent contact. Among other phenomena asserted to characterize the mediumship of Eusapia are the production of temporary prolongations from the medium's body; these have been seen in a good light by competent witnesses. It was shown in some sittings held at Cambridge in 1895 that Eusapia produced phenomena by fraudulent means: but though the evidence of this is conclusive it has not been shown that her mediumship is entirely fraudulent. Automatic records of seances can alone solve the problems raised by physical mediumship. It has been shown in the Davey-Hodgson experiments that continuous observation, even for a short period, is impossible, and that in the process of recording the observations many omissions and errors are inevitable. Even were it otherwise, no care could provide against the possibility of hallucination.

II. The genuineness of trance mediumship can no longer be called in question. The problem for solution is the source of the information. The best observed case is that of Mrs Piper of Boston; at the outset of her career, in 1884, she did not differ from the ordinary American trance medium. In 1885 the attention of Professor William James of Harvard was attracted to her; and for twenty years she remained under the supervision of the Society for Psychical Research. During that period three phases may be distinguished: (1) 1884–1897, trance utterances of a "control" calling himself Mr Phinuit, a French physician, of whose existence in the body no trace can be found; (2) 1892–1896, automatic writing by a "control" known as "George Pelham," the pseudonym of a young American author; (3) 1896 onwards, supervision by "controls" purporting to be identical with those associated with Stanton Moses. There is no evidence for regarding Mrs Piper as anything but absolutely honest. Much of the Piper material remains unpublished, partly on account of its intimate character. Many of those to whom the communications were made have been convinced that the "controls" are none other than discarnate spirits. Probably no absolute proof of identity can be given, though the reading of sealed letters would come near it; these have been left by more than one prominent psychological researcher, but so far the "controls," who claim to be the writers of them have failed to give their contents in whole or in part.

Professor Flournoy has investigated a medium of very different type, known as Hélène Smith; against her good faith nothing can be urged, but her phenomena—trance utterance and glossolalia—have undoubtedly been produced by her own mind. These represent her to be the reincarnation of a Hindu princess, and of Marie Antoinette among others, but no evidence of identity has been produced. The most striking phenomenon of her trance was the so-called Martian language, eventually shown by analysis to be a derivative of French, comparable to the languages invented by children in the nursery, but more elaborate.

Podmore, Modern Spiritualism; the Proceedings and Journal of the Society for Psychical Research, passim; for a convenient account of the Piper case, see F. Sage, Madame Piper; J. Maxwell, Les Phénomènes psychiques (1903; Eng. trans. 1905); Th. Flournoy, Des Indes à la planète Mars. For fraudulent methods, see Confessions of a medium (London, 1882); Truesdell, Bottom Feet of Spiritualism, and works cited by Myers, II, 502–503.

(1) MEDJIDIE, or MEJDIJE, the name of a military and knightly order of the Turkish Empire, and also of a silver Turkish coin, worth twenty piastres. The coin was first struck in 1844, and the order was instituted in 1852 by the sultan Abd-ul-Meijid, whose name was therefore given to them. (See KNIGHTHOOD and CHIVALRY: § Orders of Knighthood.)

MEDLAR, Mesplius germanica, a tree of the tribe Pomaceae of the order Rosaceae, closely allied to the genus Pyrus, in which it is sometimes included; it is a native of European woods, &c., from Holland southwards, and of western Asia. It occurs in hedges, &c., in middle and south England, as a small, much-branched, deciduous, spineless tree, but is not indigenous. The medlar was well known to the ancients. Pickering (Chron. Hist. Med. ii. 1, 2), refers it with a tree mentioned in a Saxon ode (She-King, ii. 1, 2), 827 a.d. It is the Melnik of Theophrastus and Mesplius of Pliny. The Latin mesplius or mespilum became in Old French mesle or molde, "the fruit," mestier, medier, "the tree." The modern French médie is from a corruption mespilum of the Latin. The German Mispel preserves the original more closely. The well-known fruit is globular, but depressed above, with leafy persistent sepals, and contains stones of a hemispherical shape. It is not fit to eat until it begins to decay and becomes "bletted," when it has an agreeable acid and somewhat astrignent flavour. Several varieties are known in cultivation. The large Dutch medlar, which is very widely cultivated, has a naturally crooked growth; the large, much-flattened fruit is inferior in quality to the Nottingham, which is a tree of upright habit with fruits of about 1 in. diameter, superior to any other variety. There is also a stonless variety with still smaller fruits, but the quality is not so good.

The medlar is propagated by budding or grafting upon the white-thorn, which is most suitable if the soil is dry and sandy, or on the quince if the soil is moist; the pear stock also succeeds
well on ordinary soils. It produces the best fruit in rich, loamy, somewhat moist ground. The tree may be grown as a standard, and chiefly requires pruning to prevent the branches from rubbing each other. The fruit should be gathered in November, on a dry day, and laid out upon shelves. It becomes "blighted" and fit for use in two or three weeks. The Japanese medlar is *Eriobotrya japonica* (see Loquat), a genus of the same tribe of Rosaceae.

**MEDOC**, a district in France adjoining the left bank of the Gironde from Blanquefort (N. of Bordeaux) to the mouth of the Gironde. Its length is about 50 m., its breadth averages between 6 and 7 m. It is formed by a number of low hills, which separate the Landes from the Gironde, and is traversed only by small streams; the Gironde itself is mucky, and often enmeshes itself in the region as a whole is far from picturesque. Large areas of its soil are occupied by vineyards, the products of which form the finest growths of Bordeaux. (See Wine.)

**MEDUSA**, the name given by zoologists to the familiar marine animals known popularly as jelly-fishes; or, to be more accurate, to those jelly-fishes in which the form of the body resembles that of an umbrella, bell or parachute. The name medusa is suggested by the tentacles, usually long and often numerous, implanted on the edge of the umbrella and bearing the stinging organs of which sea-bathers are often disagreeably aware. The tentacles serve for the capture of prey and are very contractile, being often protruded to a great length or, on the other hand, retracted and forming corkscrew-like curls. Hence the animals have suggested to vivid imaginations the head of the fabulous Gorgon or Medusa with her *chevelure* of writhing snakes.

The medusa occurs as one type of individual in the class Hydrozoa (q.v.), the other type being the polyp (q.v.). In a typical medusa we can distinguish the following parts. The umbrella-like body bears a circle of tentacles at the edge, whereby the body can be divided into a convex *exumbrella* or exumbraural surface and a concave *subumbrella* or subumbraural surface. The vast majority of jelly-fish float in the sea, with the exumbrella upwards, the subumbrella downwards. A few species, however, attach themselves temporarily or permanently to some firm object by the exumbral surface of the body, and then the subumbraural surface is directed upwards. From the centre of the subumbraural surface, and down the manubrium, like the handle of an umbrella or the clapper of a bell, bearing the mouth at its extremity. In addition to the tentacles, the margin of the umbrella bears sense-organs, which may be of several kinds and may attain a high degree of complexity.

Medusae capture their prey, consisting of small organisms of various kinds, especially Crustacea, by means of the tentacles which hang out like fishing-lines in all directions. When the prey comes into contact with the tentacles it is paralysed, and at the same time held firmly, by the barbed threads shot out from the stinging organs or nematoctyes. Then by contraction of the tentacles the prey is drawn into the mouth. Medusae thus form an important constituent of the plankton or floating fauna and contain in their mesogloea many minute animals for the food-supply furnished by minute forms of life.

A medusa has a layer of muscles, more or less strongly developed, running in a circular direction on the surface of the subumbrella, the contractions of which are antagonized by the elasticity of the gelatinous substance of the body. By the contraction of the subumbraural circular muscles the concavity of the subumbrella is increased, and as water is thereby forced out of the subumbraural cavity the animal is jerked upwards. In this way jelly-fish progress feebly by the pumping movements of the umbrella. Besides the circular subumbraural muscles, there may be others running in a radial direction, chiefly developed as the longitudinal retractor muscles of the manubrium. In some cases the circular subumbraural muscles form a rim known as the *rima bivittata*, or subumbraural ring, which is firmer, or perhaps just within the ring of marginal tentacles. The two principal divisions of the medusae are characterized by the presence or absence of a velum.

Correlated with the well-developed muscular system and sense-organs of the medusa, we find also a distinct nervous system. This, when there is no velum, in the form of concentrations of nervous matter in the vicinity of each sense-organ, or, when a velum is present, as two continuous rings running round the margin of the umbrella, one external to the velum (exumbraural nerve-ring, *n.r*). The other internal to it (subumbraural nerve-ring, *s.n.r*). The exumbraural nerve-ring is the larger and supplies the tentacles; the subumbraural ring supplies the velum.

Every possible variety of body-form compatible with the foregoing description may be exhibited by different species of medusae. The body may show modifications of form which can be compared to a shallow saucer, a cup, a bell or a thimble. The marginal tentacles may be very numerous or may be few in number or even absent altogether; or they may be simple filaments, or branched in a complicated manner. The manubrium may be excessively long or very short, and in rare cases absent, the mouth then being flush with the subumbraural surface. The mouth may be circular or four-cornered, and in the latter case the manubrium at the angles of the mouth may bear a border of spines or a row of stinging tentacles. The orificial arms, each with a groove on its inner side continuous with the corners of the mouth. The oral arms are the starting-point of a further series of variations; they may be simple flaps, wrinkled and folded in various ways, or they may be subdivided, and then the branches may simulate tentacles in appearance. In the genus Rhizostoma, common on the British coasts and conspicuous on account of its large size, the oral arms, originally distinct and four in number, undergo a comparable process of subdivision, so that the entrance to the mouth is reduced to numerous fine pores and canals.

Like the external structure, the internal anatomy of the medusa shows a complete radial symmetry, and is simple in plan but often complicated in detail (see fig. 1). As in all Hydrozoa (q.v.) the body wall is composed of two cell-layers, the ectoderm and endoderm. Between which is a structureless gelatious secreted layer, the mesogloea. As the name jelly-fish implies, the mesogloea is greatly developed and abundant in quantity. It may be traversed by processes of the cells of the ectoderm and endoderm, or it may contain cells which have migrated into it from these two layers. The ectoderm covers the whole external surface of the animal, while the endoderm lines the coelenteron or gastrovascular space; the two layers meet each other, and become continuous, at the edge of the mouth.

The mouth leads at once into the true digestive cavity, visible into an oesophageal region in the manubrium and a more dilated cavity, the stomach (st.), occupying the centre of the umbrella. From the stomach, canals arise termed the radial canals (r.); typically four in number, they run in a radial direction to the edge of the mouth.

---

1 The gooseberry-like or band-shaped jelly-fishes belong to the class Ctenophora (q.v.).

2 For other variations of the medusa, often of importance for systematic classification, see HYDROMEDUSA and SCYPOMEDUSA.
of the umbrella. There the radial canals are joined by a ring-
canal (c.c.) which runs round the margin of the umbrella. From
the ring-canal are given off tentacle-canals which run down the
axis of each tentacle; in many cases, however, the cavity of the
tentacle is obliterated, and of the coelomic canal only a solid core
of endoderm. Oesophagus, stomach, radial canals, ring-
canal and tentacle-canals, constitute together the gastro-
vascular system and are lined throughout by endoderm, which
forms a fundamental layer of all its organs, except the ring
canal together like a web; this is the so-called endoderm-lamella
(e.l.), a most important feature of medusan morphology, the
nature of which will be apparent when the development is
described. As a general rule the mouth is the only aperture of the
gastrovascular system; in a few cases, however, excretory pores
are found on the ring-canal, but there is never any anal opening.

The sense-organs of medusae are of two classes: (1 pig-
ment spots, sensitive to light, termed ocelli, which may become elaborated
into a ring gland; and (2) organs of the sense of balance or orientation, com-
monly termed otocysts or statocysts. The sense-organs are always situated at
the margin of the umbrella and may be distinguished from the mor-
phological parts so placed that in certain species they are obliterated and it
is not, derived from modifications of tentacles; in the former case
they are termed tentaculars. (For fuller information upon the
sense-organs see Hydromedusae.)

In development the medusa can be derived easily by process of
differentiation of four cell-layers, combined with compression and
asymmetry, from the actinula-larva. (For figures see Hydroido-
a.) The actinula is polyplike, with a sack-like or rounded body; a crown of
tentacles surrounds a wide peristome, in the centre of which is the mouth,
usually two to four in number. After a few days they may be
produced a medusa the actinula grows greatly along a plane at right
angles to the vertical axis of the body, whereby the aboral surface
of the actinula becomes the exumbrella, and the peristome becomes the
mouth. The exumbrella descends as a frill to the margin of the
mouth, and the hypostome becomes the manubrium. As a result of this change
of form the gastric cavity or coelenteron becomes of compressed lenticular
form, and the gastric axis is limited by the manubrial wall and the
umbrella is a simple or double layer of cells, one or more subumbilical
laye and a lower or subumb nibular layer. The next event is a great
growth in thickness of the gelatinous mesogloea, especially on the
exumbrella; as a result the flattened coelenteron is still further con-
stricted, combined with compression and asymmetry, and it is
embraced by the umbrellal and subumbrellal layers of endoderm
come into contact and undergo concrescence. As a rule four such areas of
concrescence or cathamata (E. Haeckel) are formed. The cathamal areas
may be produced in nests, resembling menhirs, which may
be produced in four lobed stomach, the lobes of which
communicate at the periphery of the body by a spacious ring-
canal. More usually each cathamata is a wide triangular area, reducing
from the broad base towards the point, and one or two subumbibial
and two or more subumbilical rings of canal canals and the ring-canal above described. The two apposed
layers of endoderm in the cathamal area undergo complete fusion to
form a single layer of epithelium, the endoderm-lamella of the
adult medusa.

Medusae, when they reproduce themselves by budding, always
produce medusae, but when they reproduce by the sexual method
the embryos produced from the egg grow into medusae in some
cases, in other cases into polyps, which in bud medusae in their turn.
In some cases, the coelom is produced by elongation of the
water-urn, which are described in the Hydromedusae and Scyphomedusae.

Medusae are exclusively aquatic animals and for the most part
marine, but at least two fresh-water species are known. 1 Limno-
= Medusa. Medusae are found in fresh water, but also in brackish
water, Victoria regia, is cultivated in Kew Gardens, and

recorded the discovery of a third species by himself and W. A.
Cunnington, in the brackish water of lake Birket el Kerun in the
Egyptian Fayum.

has since been found sporadically in a similar situation in other
botanical gardens, its most recent appearance being at Lille.
These jelly-fishes are probably budded from a minute polyp-stock
introduced with the roots of the lily. Another fresh-water form is
Lemnocris tanganicae, discovered in lake Tanganyika, and
now known to occur also in the Victoria Nyanza and in the Niger.
A medusa with a remarkable habit of life is Menestra parasites,
which is parasitic on the pelagic mollusc Psyllidens, attaching itself
by the tentacles. The adult medusa is always ready to shed its
body for obtaining food, have become rudimentary. A parasitic mode
of life is also seen in medusae of the genus Cunina during the larval
condition, but the habit is abandoned, in this case, when the medusa
becomes adult.

For figures of medusae see (1) E. Haeckel, "Das System der
Medusen," Denkschriften med-nat., Ges. Jena (1879, 2 vols.); (2)

(M. A. Y.)

MEDWAY, a river in the south-east of England. It rises in
the Forest Ridges, S.W. of East Grinstead in Sussex, and,
increased by many feeders from these picturesque hills, has an
average width of about 100 yd., passes through the suburban
London, and Entering Kent near Ashur-
the course becomes north-easterly, and this direction is generally
maintained to the mouth. The water passes Tonbridge, receiving
the Eden from the west, and later the Teise and Bult from the
south and east, all these streams watering the rich Weald (g.v.)
to the south of the North Downs. These hills are breached by
the Medway in a beautiful valley, in which lies Maidstone,
generally much narrower than the upper valley. The charac-
teristic structure of this part of the valley is considered under the
heading Downs. Below Maidstone the valley forms a perfect
basin, the hills descending upon it closely above Rochester.
Below this city the river enters a broad, winding estuary, passing
Chatham, and at Sheerness joining that of the Thames, so that
the Medway may be considered a tributary, and its drainage area
of 680 sq. m. reckoned as part of that of the greater river.
The length of the Medway is about 62 m., excluding its
my lesser windings. The estuary is navigable for sea-going vessels
during 24 miles up to Rochester Bridge. A considerable traffic
is carried on by small vessels up to Maidstone, and by barges up to
Tonbridge, the total length of the navigation being 43 m.
The marsh lowlands along the course of the river have yielded exten-
se remains of Roman pottery, a plain ware of dark slate-colour.

MEEANEER, or MANG, a village in Sind, India, on the Indus
6 m. N. of Hyderabad. Pop. (1901), 662. It is famous as
the scene of the battle in which Sir Charles Napier, with only
2800 men, broke the power of the mirs of Sind on the 17th
February 1843. The result of this victory was the conquest
and annexation of Sind.

MEEK, FIELDING BRADFORD (1817-1879), American
geologist and palaeontologist, the son of a lawyer, was born
at Madison, Indiana, on the 10th of December 1817. In early
life he was in business as a merchant, but his leisure hours were
devoted to collecting fossils and studying the rocks of the neigh-
bourhood of Madison. Being unsuccessful in business he turned
his whole attention to science, and in 1848 he gained employment
as an agent on the United States Geological Survey in Iowa,
Wisconsin and Minnesota. In 1852 he became assistant to Pro-
fessor James Hall at Albany, and worked at palaeontology with
him until 1858. Meanwhile in 1853 he accompanied Dr. F. V.
Hayden in an exploration of the " Bad Lands " of Dakota, and
brought back valuable collections of fossils. In 1858 he went
to Washington, where he devoted his time to the palaeontological
work of the United States geological and geographical surveys,
his work bearing "the stamp of the most faithful and con-
scientious research," and raising him to the highest rank as a
palaeontologist. Besides many separate contributions to science,
he prepared with W. M. Gabb (1830-1878), two volumes on
the palaeontology of California (1864-1865); and also a Report
on the Invertebrate Cretaceous and Tertiary Fossils of the Upper
Missouri Country (1876). He died at Washington, on the 22nd
of December 1876.
MEER—MEERSCHAUM

MEER, JAN VAN DER (1632-1673), more often called Vermeer of Delft—not to be confounded with the elder (1628-1691) or younger (1636-1705) Van der Meer of Haarlem, or with Van der Meer of Utrecht—is one of the excellent Dutch painters about whom the Dutch biographers give us little information.1 Van der Meer, or Vermeer, was born in Delft, and was a pupil of Carel Fabritius, whose junior he was by only eight years. The works by Fabritius are few, but his contemporaries speak of him as a man of remarkable power, and the paintings now ascertained to be from his hand, and formerly ascribed to Rembrandt, prove him to have been deeply imbued with the spirit and manner of that master. Whether Van der Meer had ever any closer relation to Rembrandt than through companionship with Fabritius remains uncertain. In 1653 he married Catherine Bolens, and in the same year he entered the guild of St. Luke of Delft, becoming out of the head of the guild in 1662 and again in 1670. He died at Delft in 1675, leaving a widow and eight children. His circumstances cannot have been flourishing, for at his death he left twenty-six pictures undisposed of, and his widow had to apply to the court of insolvency to be placed under a curator, who was Leeuwenhoek, the naturalist.

For more than two centuries Van der Meer was almost completely forgotten, and his pictures were sold under the names and forged signatures of the more popular De Hooch, Metsu, Ter Borch, and even of Rembrandt. The attention of the art-world was first recalled to this most original painter by Thoré, an exiled Frenchman, who described his then known works in *Mémoires de l'Académie des Beaux-Arts de France* (1858-1866), published under the assumed name of Prosper Leclerc, a bibliomaniac and book-thief, who put together in his Galerie Suermondt and Galerie d'Arenberg, was afterwards given by him a charming, though incomplete, monograph (Gazette des beaux-arts, 1866, pp. 297, 438, 542). The task was prosecuted with success by Havard (Les Artistes hollandais, and by Opreen (Nederlandse Kunstgeschiedenis, D. iv.), and we are now in a position to refer to Van der Meer's works. His pictures are rarely dated, but one of the most important, in the Dresden Gallery, bears the date 1656, and thus gives us a key to his styles. With the exception of the "Christ with Martha and Mary" in the Coats collection at Glasgow, it is perhaps the only one, hitherto recognized, that has figures of life size, though his authorship is claimed for several others. The Dresden picture of a "Woman and Soldier," with other figures, is painted with remarkable power and boldness, and with great command over the resources of colour, and with wonderful expression of life. For strength and colour it more than holds its own beside the neighbouring Rembrandts. To this early period of his career belong, from internal evidence, the "Reading Girl" of the same gallery, the luminous and masterly "View of Delft" in the museum of the Hague, the "Milk-Woman" and the small street view, both identified with the Six collection at Amsterdam, the former now in the Rijksmuseum; the magnificent "The Letter" also at Amsterdam, "Diana and the Nymphs" (formerly ascribed to Vermeer of Utrecht) at the Hague Gallery, and others. In all these we find the same brilliant style and vigorous work, a soft, impalpable "Woman and Soldier," with others, that first seems to have been influenced by the pleiad of painters circling round Rembrandt, a school which lost favour in Holland in the last quarter of the century. During the final ten or twelve years of his life Van der Meer adopted a second manner. We now find his painting smooth and thin, and his colours paler and softer. Instead of masculine vigour we have refined delicacy and subtlety, but in both styles beauty of tone and perfect harmony are conspicuous. Through all his work may be traced his love of lemon-yellow and of blue of all shades.

Of his second style typical examples are to be seen in "The Coquette" of the Brunswick Gallery, in the "Woman Reading" in the Van der Hoop collection now at the Rijksmuseum at Amsterdam, in the "Lady at a Casement" belonging to Lord Powerscourt (exhibited at the Royal Academy, 1878) and in the "Music Master and Pupil" belonging to the King (exhibited at the Royal Academy, 1876).

Van der Meer's authentic pictures in public and private collections amount to about thirty. There is but one in the Louvre, the "Lace Maker", Dresden has the two aforementioned, while Berlin has three, all acquired in the Suermondt collection, and the Caernin Gallery of Vienna is fortunate in possessing a fine picture, believed to represent the artist in his studio. In the Arengem Gallery at Brussels there is a remarkable head of a girl, half the size of life, which seems to be intermediate between his two styles. Several of his paintings are in private foreign collections. In all his work there is a singular completeness and charm. His tone is usually silvery with pearly shadows, and the lighting of his interiors is equal and natural. In all cases his figures seem to move in light and air, and in this respect he resembles greatly his fellow-worker De Hoogh. It is curious to read that, at one of the auctions in Amsterdam about the middle of the 18th century, a De Hoogh is praised as being "nearly equal to the famous Van der Meer of Delft."

See also Havard, Van der Meer (Paris, 1888); Van zyvpe, Vermeer de Delft (Brussels, 1980), and Hofstede de Groot, Jan Vermeer van de Delft (Leipzig, 1909).

MEERANE, a town in the kingdom of Saxony, 9 m. N. of Zwicau and 37 S. of Leipzig by rail. Pop. (1905), 26,005. It contains a fine medieval church (Evangelical). It is one of the most important industrial centres of Germany for the manufacture of woollen and mixed cloths, and in these products has a large export trade, especially to eastern Europe and the Baltic States.

There are also extensive dyeworks, tanneries and machine factories. See Leopold, *Chronik und Beschreibung der Fabrik- und Handelsstadt Meerane* (1886).

MEERSCHAUM, a German word designating a soft white, mineral sometimes found floating on the Black Sea, and rather suggestive of sea-foam (meerschaum), whence also the French name for the same substance, écume de mer. It was termed by E. F. Glocker sepiolite, in allusion to its resemblance to the "bone" of the sepia or cuttle-fish. Meerschaum is an opaque mineral of white, grey or cream colour, breaking with a conchoidal or fine earthy fracture, and occasionally though rarely, fibrous in texture. It can be readily scratched with the nail, its hardness being about 2. The specific gravity varies from 0.988 to 1.275, but the porosity of the mineral may lead to error. Meerschaum is a hydrous magnesium silicate, with the formula H₄Mg₂Si₄O₁₀, or Mg₃Si₄O₁₀·2H₂O.

Most of the meerschaum of commerce is obtained from Asia Minor, chiefly from the plain of Eski-Shehr, on the Haldar Pasha-Angora railway, where it occurs in irregular nodular masses, in alluvial deposits, which are extensively worked for its extraction. It is said that in this district there are 4000 to 5000 acres of meerschaum outcrop, and that the annual output of meerschaum is 100,000 tons. The principal workings are at Sepetdjij-Ojdjagh and Kemikdji-Ojdjagh, about 20 m. S.E. of Eski-Shehr. The mineral is associated with magnetite (magnesium carbonate), the primitive source of both minerals being a serpentine. When first extracted the meerschaum is soft, but it hardens on exposure to solar heat or when dried in a warm room. Meerschaum is found also, though less abundantly, in Greece, as at Thbes, and in the islands of Euboea and Samos; it occurs also in serpentine at Hrubischitz near Kromau in Moravia. It is found to a limited extent at certain localities in France and Spain, and is known in Morocco. In the United States it occurs in serpentine in Pennsylvania (as at Nottingham, Chester county) and New York (see Meerschaum and Serpentine). Meerschaum has occasionally been used as a substitute for soap and fuller's earth, and it is said also as a building material; but its chief use is for tobacco-pipes and cigar-holders. The
natural nodules are first scraped to remove the red earthy matrix, then dried, again scraped and polished with wax. The rudely shaped masses thus prepared are sent from the East to Vienna and other manufacturing centres, where they are turned and carved, smoothed with glass-paper and Dutch rashes, heated in wax or steerine, and finally polished with bone-ash, &c. Imitations are made in plaster of Paris and other preparations.

The soft, white, earthy mineral from Långbanshyttan, in Värmland, Sweden, known as aphrodite (эффект, foam), is closely related to meerschaum. It may be noted that meerschaum has sometimes been called magnesite (q.e.).

MEERUT, a city, district and division of British India, in the United Provinces. The city is half-way between the Ganges and the Jumna, and has two stations on the North-Western railway, 37 m. N.E. from Delhi. Pop. (1901), 118,129. The city proper lies south of the cantonments, and although dating back to the days of the Buddhist emperor Asoka (c. 250 B.C.) Meerut owes its modern importance to its selection by the British government as the site of a great military station. In 1805 it is mentioned as "a ruined, depopulated town." The cantonment was established in 1806, and the population rose to 29,014 in 1847, and 82,035 in 1853. The town is an important centre of the cotton-trade. It is the headquarters of the 7th division of the northern army, with accommodation for horse and field artillery, British and native cavalry and infantry. It was here that the first outbreak of the Mutiny of 1857 took place. (See Indian Mutiny.)

The District of Meerut forms part of the upper Doab, or tract between the Ganges and the Jumna, extending from river to river. Area, 2354 sq. m. Though well wooded in and abundantly supplied with mango groves, it has but few patches of jungle or waste land. Sandy ridges run along the low watersheds which separate the minor channels, but with this exception the whole district is one continuous expanse of careful and prosperous tillage. Its fertility is largely due to the system of irrigation canals. The Eastern Jumna canal runs through the whole length of the district, and supplies the rich tract between the Jumna and the Jumna with a network of distributary streams. The main branch of the Ganges canal passes across the centre of the plateau in a sweeping curve and waters the midland tract. The Anupshahr branch supplies irrigation to the Ganges slope, and the Agra canal passes through the southern corner of Loni pargana from the Hindan to the Jumna. Besides these natural and artificial channels, the country is everywhere cut up by small water-courses. The Burh Ganga, or ancient bed of the Ganges, lies at some distance from the modern stream; and on its banks stand the abandoned city of Hastinapura, the legendary capital of the Pandavas at the period of the Mahâbhârata, said to have been deserted many centuries before the Christian era, owing to the encroachments of the river.

The comparatively high latitude and elevated position of Meerut make it one of the healthiest districts in the plains of India. The average temperature varies from 57° F. in January to 85° in June. The rainfall is small, less than 30 in. annually. The only endemic disease in the district is malarial fever; but small-pox and cholera occasionally visit it as epidemics. The population in 1901 was 1,540,175, showing an increase of 10.6% in the decade. The principal crops are wheat, pulse, millet, sugar-cane, cotton and indigo, but this last crop has declined of late years almost to extinction. The district is traversed by the North-Western railway, and also contains Ghaziabad, the terminus of the East Indian system, whence a branch runs to Delhi, while a branch of the Oudh & Rohilkhand railway from Moradabad to Ghaziabad was opened in 1900.

The authentic history of the district begins with the Moslem invasions. The first undoubted Mahommedan invasion was that of Kutbeddin in 1191, when Meerut town was taken and all the Hindu temples turned into mosques. In 1398 Timur captured the fort of Loni after a desperate resistance, and put all his Hindu prisoners to death. He then proceeded to Delhi, and after his memorable sack of that city returned to Meerut, captured the town, razed all the fortifications and houses of the Hindus and put the male inhabitants to the sword. The establishment of the great Mogul dynasty in the 16th century, under Baber and his successors, gave Meerut a period of internal tranquillity and royal favour. After the death of Aurangzeb, however, it was exposed to alternate Sikh and Maharrâta invasions. From 1707 till 1775 the country was the scene of perpetual strife, and was only rescued from anarchy by the exertions of the military adventurer Walter Reinhardt, afterwards the husband of the celebrated Begum Samru, who established himself at Sardhana in the north, and ruled a large estate. The southern tract, however, remained in its anarchic condition under Maharrâta exactions until the fall of Delhi in 1803, when the whole of the country between the Jumna and the Ganges was ceded by Sindhia to the British. It was formed into a separate district in 1818. In the British period it has become memorable for its connexion with the Mutiny of 1857.

The Division of Meerut comprises the northern portion of the Drang. It consists of the six districts of Dehra Dun, Saharanpur, Muzaffarnagar, Meerut, Bulandshahr and Aligarh. Area, 41,302 sq. m.; pop. (1901), 5,979,711, showing an increase of 12.3% in the decade.

See Meerut District Gazetteer (Allahabad, 1904).

MEETING (from "to meet," to come together, assemble, O. Eng. mèten; cf. Du. moeten, Swed. möta, Goth. gamotian, &c.; derivatives of the Teut. word for a meeting, seen in O. Eng. môt, mooting, an assembly of the people; cf. wilanagemot), a gathering together of persons for the purpose of discussion or of the transactin of business. Public meetings may be either those of statutory bodies or assemblies of persons called together for social, political or other purposes. In the case of statutory bodies, by-laws usually fix the quorum necessary to constitute a legal meeting. That of limited companies may be either by reference to the capital held, or by a fixed quorum or one in proportion to the number of shareholders. It has been held that in the case of a company it takes at least two persons in meeting (Sharp v. Davies, 1836, 2 Q.B.D. 26). In the case of public meetings for social, political or other purposes no quorum is necessary. They may be held, if they are for a lawful purpose, in any place, on any day and at any hour, provided they satisfy certain statutory provisions or by-laws made under the authority of a statute for the safety of persons attending such meetings. If, however, a meeting is held in the street and it causes an obstruction those convening the meeting may be proceeded against for obstructing the highway. The control of a meeting and the subjects to be discussed are entirely within the discretion of those convening it, and whether the meeting is open to the public without payment, or subject to a charge or to membership of a specified body or society, those present are there merely by virtue of a licence of the convenors, which licence may be revoked at any time. The person whose licence is revoked may be requested to withdraw from the meeting, and on his refusal may be ejected with such force as is necessary. If he employs violence to those removing him he commits a breach of the peace for which he may be given into custody. An important English act has dealt for the first time with the disturbance of a public meeting. The Public Meeting Act 1908 enacted that any person who at a lawful public meeting acts in a disorderly manner for the purpose of preventing the trans- action of the business for which the meeting was called together shall be guilty of an offence, and if the offence is committed at a political meeting held in any parliamentary constituency between the issue and return of a writ, the offence is made an illegal practice within the meaning of the Corrupt and Illegal Practices Prevention Act 1883. Any person who incites another to commit the offence is equally guilty. A public meeting is usually controlled by a chairman, who may be appointed by the conveners or elected by the meeting itself. On the chairman falls the duty of preserving order, of calling on persons to speak, deciding points of order, of putting questions to the meeting
MEGALOPOLIS

for decision, and declaring the result and other incidental matters.

In England it is illegal, by a statute of George III. (Seditious Meetings Act 1817), to hold a public meeting in the open air within 1 m. of Westminster Hall during the sitting of Parliament.

MEGALOPOLIS, an ancient city of Arcadia, Greece, situated in a plain about 20 m. S.W. of Tegea, on both banks of the Helisson, about 2½ m. above its junction with the Alpheus. Like Messene, it owed its origin to the Theban general Epaminondas, and was founded in 370 B.C., the year after the battle of Leuctra, as a bulwark for the southern Arcadians against Sparta, and as the seat of the Arcadian Federal Diet, which consisted of ten thousand men. The builders were protected by a Theban force, and directed by ten native seists (official "founders"),

who likewise attended to the peopling of the new city, which apparently drew inhabitants from all parts of Arcadia, but especially from the neighbouring districts of Maenalus and Parrhasia. Forty townships are mentioned by Pausanias (viii. 27, 3-5) as having been incorporated in it. It was 50 stadia in circumference, and was surrounded with strong walls. Its territory was the largest in Arcadia, extending northward 24 m. The city was built on a magnificent scale, and adorned with many handsome buildings, both public and private. Its temples contained many ancient statues brought from the towns incorporated in it. After the departure of Epaminondas, Lycomedes of Mantinea succeeded in drawing the Arcadian federation away from its alliance with Thebes, and it was consequently obliged to make common cause with Athens. An attempt on the part of the federation to use the treasures of the temple of Zeus at Olympia led to internal dissensions, so that in the battle of Mantinea (362) one half of the Arcadians fought on the side of the Spartans, the other on that of the Thebans. After this battle many of the inhabitants of Megalopolis sought to return to their former homes, and it was only by the assistance of three thousand Thebans under Pammenes that the authorities were able to prevent them from doing so. In 353, when Thebes had her hands full with the so-called Sacred War, the Spartans made an attempt to reduce Megalopolis; but the Thebans sent assistance and the city was rescued. Not sure of this assistance, the Megalopolitans had appealed to Athens, an appeal which gave occasion to the oration of Demosthenes, Περὶ Μεγαλοπολίτων. The Spartans were now obliged to conclude peace with Megalopolis and acknowledge her autonomy. Nevertheless their feeling of hostility did not cease, and Megalopolis consequently entered into friendly relations with Philip of Macedon. Twenty years later, when the Spartans and their allies rebelled against the power of Macedon, Megalopolis remained firm in its allegiance, and was subjected to a long siege. After the death of Alexander, Megalopolis was governed by native tyrants. In the war between Cassander and Polyperchon it took part with the former and was besieged by the latter. On this occasion it was able to send into the field an army of fifteen thousand.

In 234 B.C. Lydiades, the last tyrant of Megalopolis, voluntarily resigned his power, and the city joined the Achaean League. In consequence of this it was again exposed to the hatred of Sparta. In 222 Cleomenes plundered it and killed or dispersed its inhabitants, but in the year following it was restored and its inhabitants reinstated by Philopoemen, a native of the city. After this, however, it gradually sank into insignificance. The only great men whom it produced were Philopoemen and Polybius the historian. Lycoctas, the father of the latter, may be accounted a third. In the time of Pausanias the city was mostly in ruins.

The site of Megalopolis was excavated by members of the British School at Athens in the years 1890-1892. The description of Pausanias is so clear that it enabled Curtius, in his Peloponnesos, to give a conjectural plan that was found to tally in most respects with the reality. The town was divided into two approximately equal parts by the river Helisson, which flows through it from east to west. The line of the walls may be traced, partly by remains, partly by the contours it must have followed, and confirms the estimate of Polybius that they had a circuit of 50 stades, or about 5½ m. It is difficult to see how the river bed, now a broad and shingly waste, was dealt with in ancient times; it must have been embanked in some way, but there are no remains to show whether the fortification wall

MEGALOPOLIS.
was carried across the river at either end or along the parallel embankments so as to make two separate enclosures. There must have been, in all probability, a bridge to connect the two halves of the city, but the foundations seen by Leake and others, and commonly supposed to belong to such a bridge, proved to be only the substructures of the precinct of Zeus Soter. The buildings north of the river were municipal and were grouped round the square agora. One, of which the complete plan has been recovered, is the portico of Philip, a splendid building, which bounded the agora on the north; it was 300 ft. long, with three rows of columns running its whole length, three in the outer line to each one in the two inner lines; it had a slightly projecting wing at either end. At the south-west of the agora was found the precinct of Zeus Soter: it consists of a square court surrounded by a double colonnade, and faced on the west side by a small temple; on the east side was an entrance or propylaeum approached by a ramp. In the midst of the court was a substructure which has been variously interpreted as an altar or as the base of the great group of Zeus and Megalopolis, which is recorded to have stood here. North of this was the Stoa Myropolis, forming the east boundary of the agora, and, between this and the Stoa of Philip, the Arechia or municipal offices. These buildings were of various dates, but seem all to fit into an harmonious plan. The buildings on the south and west of the agora have been almost entirely destroyed by the Helisson and a tributary brook. On the south bank of the river were the chief federal buildings, the theatre (noted by Pausanias as the largest in Greece), and the Thersilion or parliament hall of the ten thousand Arcadians. These two buildings form part of a common design, the great portico of the Thersilion facing the orchestra of the theatre. As a consequence of this arrangement, the plan of the theatre is abnormal. The auditorium has as its lowest row of seats a set of "thrones" or ornamental benches, which, as well as the gutter in front, were dedicated by a certain Arachondrus; the orchestra is about 100 ft. in diameter; and in place of the western parados is a closed room called the Scantheca. The chief peculiarity, however, lies in the great portico already mentioned, which has its base about 4 ft. 6 in. above the level of the orchestra. It was much too lofty to serve as a proscenium; yet, if a proscenium of the ordinary Greek type were erected in front, it would hide the lower part of the columns. Such a proscenium was actually erected in later times; and beneath it were the foundations for an earlier wooden proscenium, which was probably erected only when required. In later times steps were added, leading from the base of the portico to the level of the orchestra. The theatre was probably used, like the theatre at Athens, for political assemblies; but the adjoining Thersilion provided covered accommodation for the Arcadian ten thousand to sit in and watch the performances. The Thersilion was stretched out by Philip of Macedon and its roof extended, so that the proscenium (which rose above the level of the orchestra) took the place of the portico. The roof was supported by columns that were placed in lines radiating from the centre, so as to obscure as little as possible the view of an orator in this position from all parts of the building; there were two entrances in each side.

See Excavations at Megalopolis (E. A. Gardner, W. Loring, G. C. Richards, W. J. Woodhouse; Architecture, by R. W. Schultz); Supplementary Paper issued by the Society for the Promotion of Hellenic Studies, 1892; Journal of Hellenic Studies, xiii. 328, A. C. Bather: "Heraion, or the Thersilion, p. 15; J. B. Bury ("Double City"); W. Dörpfeld ("Das griechische Theater"); O. Puchstein, "Griechische Bühne" (Theatre). (E. Gr.)

MEGANUCLEUS (also called MACRONUCLEUS), in Infusoria (q.v.), the large nucleus which undergoes direct (amitotic) division in fission, and is lost during conjugation, to be replaced by a nucleus, the result of the karyogamy of the micronuclei.

MEGAPODE (Gr. μεγας, great and τως, foot), the name given generally to a small but remarkable family of birds, characteristic of some parts of the Australian region, and peculiar. The Megapodiidae, with the family Cracidiae and Phasianidae, form that division of the sub-order Galli named by Huxley Peristeropodes (Proc. Zool. Soc. 1868, p. 296). Their most remarkable habit is that of laying their eggs to be hatched without incubation, burying them in the ground (as many reptiles do), or in a mound of earth, leaves and rotten wood which they scratch up. This habit attracted attention nearly four hundred years ago, but the accounts given of it by various travellers were generally discredited, and as examples of the birds, probably from their unattractive plumage, appear not to have been brought to Europe, no one of them was seen by any ornithologist or scientifically described until near the end of the first quarter of the 19th century. The first member of the family to receive authoritative recognition was one of the largest, inhabiting the continent of Australia, where it is known as the brush-turkey, and was originally described by J. Latham in 1821 under the misleading name of the New Holland vulture. It is the Cathelurus lathami of modern ornithologists, and is nearly the size of a hen turkey. This East Australian bird is of a sooty-brown colour, relieved beneath by the lighter edging of some of the feathers, but the head and neck are nearly bare, beset with fine bristles, the skin being of a deep pinkish-red, passing above the breast into a large wattle of bright yellow. The tail is commonly carried upright and partly folded, something like that of a domestic fowl. Allied to it are three or four species of Talegallus, from New Guinea and adjacent islands.

Another form, an inhabitant of South and West Australia, commonly known in England as the mallee-bird, but to the colonists as the "native pheasant"—the Lipoa ocellata, as described by J. Gould in the Proc. Zool. Soc. (1840), p. 126, has much shorter tarsi and toes, the head entirely clothed, and the tail expanded. Its plumage presents a combination of greys and browns of various tints, interspersed with black, white and buff, the wing-coverts and feathers of the back bearing each near the tip an oval or circular patch, whence the name of brush-turkey. The feathers of the tail, however, have a median line of white extending down the front of the throat from the chin to the breast. There is but one species of this genus known, as is also the case with the next to be mentioned, a bird long known to inhabit Celebes, but not fully described.

1 Antonio Pigafetta, one of the survivors of Magellan's voyage, records in his journal, under date of April 25, 1521, among the peculiarities of the Philippine Islands, then first discovered by Europeans, the existence of a bird of a bird named "Tapun," which laid its eggs, as big as a duck's, in the sand, and left them to be hatched by the heat of the sun (Premier voyage autour du monde, ed. Amoretti, Paris, A.R. ix. 88). More than a hundred years later the J. Niegeremborg, in his Historia naturae, published at Antwerp in 1653, described (p. 207) a bird called "Daie," and by the natives named "Tapun," not larger than a dove, which, with its tail (!) and feet excavated a nest in sandy places and laid therein eggs bigger than those of any other bird. (Voi. i.) One of the survivors of Magellan's voyage, the traveler called "Tobon," and in the second voyage of Magellan's, published by S. Martini in 1598, described (p. 329) a bird named "Tumpan," respectively, and omitted his predecessor's important addition "Vuiut in Philippinis." Not long after, the Dominican Navarrete, a missionary to China, made a considerable stay in the Philippines, and in his famous work, Cum non est in Asia, published at Rome in 1561, mentioned "Vuiut, or Tapun," and to这不是 bird, which, with its tail (!) and feet excavated a nest in sandy places and laid therein eggs bigger than those of any other bird. (Voi. i.) One of the survivors of Magellan's voyage, the traveler called "Tobon," and in the second voyage of Magellan's, published by S. MEGARA—MEGARA HYBLAEA

described until 1846, when it received from Salomon Müller (Arch. f. Naturgeschichte, xii. pt. 1, p. 116) the name of *Macrocephalon moleo*, but, being shortly afterwards figured by Gray and Mitchell (Gen. Birds, iii. pl. 133) under the generic term *Megacephalon*, has since commonly borne the latter appellation. This bird bears a helmet-like protubercance on the back of its head, all of which, as well as the neck, is bare and of a bright red colour; the plumage of the body is glossy black above, and beneath roseate-white.

Of the megapodes proper, constituting the genus *Megapodius*, about fifteen species are admitted. The birds of this genus range from the Samoa Islands in the east, through the Tonga group, to the New Hebrides, the northern part of Australia, New Guinea and its neighbouring islands, Celebes, the Pelew Islands and the Ladrone, and have also outliers in detached portions of the Indian Region, as the Philippines (where indeed they were first discovered by Europeans), Labuan, and even the Nicobars—though none is known from the intervening islands of Borneo, Java or Sumatra. Within what may be deemed their proper area they are found, says A. R. Wallace (Geogr. Distri. Animals, ii. 431), “on the smallest islands and sandbanks, and can evidently pass over a few miles of sea with ease.” Indeed, proof of their roaming disposition is afforded by the fact that the bird described by Lesson (Voy. Coquille: Zoologie, p. 703) as *Alectheia urssili*, but now considered to be the young of *Megapodius frequicinetii*, flew on board his ship when young more than 2 m. from the nearest land (Güébé), in an exhausted state, it is true, but that may be attributed to its youth. The species of *Megapodius* are about the size of small fowls, the head generally crested, the tail very short, the feet enormous, and, with the exception of *M. wallaci* (Proc. Zool. Soc., 1866, Aves, pl. 171), from the Moluccas, all have a sombre plumage.

Megapodes are shy terrestrial birds, of heavy flight, and omnivorous diet. In some islands they are of little importance, although the flesh is dark and generally unpalatable. (A. N.)

MEGARA, an ancient Greek town on the road from Attica to Corinth. The country which belonged to the city was called *Megapoli* or *Megapos*; it occupied the broader part of the isthmus between Attica, Boeotia, Corinth, and the two gulfs, and its whole area is estimated by Clinton at 143 sq. m. The range of Mount Geraneia extends across the country from east to west, forming a barrier between continental Greece and the Peloponnesus. The shortest road across this range passes along the eastern side of the mountains, and the most difficult part is the celebrated Scironian rocks, the mythic home of the robber Sciron. The only plain in the rugged little country was the White Plain, in which was situated the only important town, Megara. The modern town of Megara is situated on two low hills which formed part of the ancient site; it is the chief town of the eparchy of Megara; pop. about 6400. It contains few remnants of antiquity, except of the ancient acropolis, and said to have been made by the architect Eupyalus for the tyrant Theagenes. (E. G.)

From the somewhat conflicting evidence of mythology it may be gathered that in prehistoric days Megara had maritime intercourse with the southern Aegean. The early inhabitants, whose race was unknown, were extirpated or absorbed in the Dorian migration, for in historic times the city had a homogeneous Dorian population. Favoured by its proximity to two great waterways and by its two ports, Nisaea on the Saronic and Pegae on the Corinthian Gulf, Megara took a prominent part in the commercial expansion of Greece from the 8th century onwards, and for two hundred years enjoyed prosperity out of proportion to the slight resources of its narrow territory. It was trade was mainly directed towards Sicily, where Megarian colonies were established at Hybla (Megara Hyblaea) and Selinus, and towards the Black Sea, in which region the Megarians were probably pioneers of Greek commerce. In the Sea of Marmora they had to face the competition of the Samians, with whom they waged a war concerning the town of Perinthus, and of Miletus; but on the Bosporus they established themselves by means of settlements at Chalcedon and, above all, Byzantium (founded, according to tradition, 675 and 658 respectively). In the Black Sea they exploited the shores of Pontus and Scythia, whose products they exchanged for textiles spun from the wool of their own country. Their chief colonies in this sea were Astacus and Heraclea in Bithynia, and another Heraclea in the Crimea. In the later 7th century this current of trade dwindled in face of the great commercial and colonizing activity of Miletus; it probably received further injury through the subsequent interference of Athens on the Hellespont. Simultaneously Megarian commerce in Sicily began to be supplanted by Corinth and Corcyra.

Megara's economic development entailed a change in the distribution of wealth, and consequently of political power, which is described upon the pages of Theognis (584-6), in the original land-holding aristocracy, which had probably initiated and for a time monopolized commerce, was partly supplanted by prosperous upstarts, and with the general increase of prosperity began to lose its power. But after the prosperity of the city had been exhausted, it struggles the city passed under a tyrant, Theagenes (about 640), whose rule was too brief to produce great changes. The power of the nobles would seem to have been more effectively broken in a future tyrant, Antigonus (about 490). The Athenians retaliated by placing an embargo upon Megarian trade throughout their empire (432), and in the Peloponnesian War, which the Megarians had consequently strenuously to hasten on, reduced their neighbours to misery by blockade and famine. In 443, a name of the nearest town of Salamis (about 570, see SOLON), for shortly afterwards the constitution was changed to a democracy, and eventually fixed as an oligarchy of a moderate type.

In the Peloponnesian War, the state, which had recently joined the Peloponnesian League, could still muster 3000 hoplites. But the subsequent expansion of Athens ruined the commerce of Megara, and the town itself was threatened with absorption by some powerful neighbour. In 418 the nearly captured Megara, in coalition with a democratic party within the town, and succeeded in securing Sicily, which they held till 410. In the 4th century Megara recovered some measure of prosperity, but played an insignificant part in the Peloponnesian Wars, and was finally reduced in the final conflict against Philip II of Macedon (338). During the Macedonian supremacy the town passed in turn from Cassander and Demetrius Poliorcetes to Antigonus Gonatas, and finally was united in 281 B.C. to the Antigonid empire. It was again destroyed during the Civil War of 48 B.C., but seems at some later period to have received new settlers. It maintained itself as a place of some size in subsequent centuries, but was depopulated by the Venetians in A.D. 1500. The inhabitants of the modern village are mostly of Albanian origin. In literature Megara figures as the reputed home of the comic Satirion, and in the 4th century gave its name to a school of philosophers founded by Eukles. (A. N.)

MEGARA HYBLAEA (perhaps identical with *Hybla Major*), an ancient city of Sicily, on the E. coast, 12 m. N.N.W. of Syracuse, founded in 728 B.C. by Megarcean colonists, who had previously settled successively at Trotolon, Leontini and Thapsus. A hundred years later it founded Selinus, apparently because it had no room for development. It never seems to have been a town of great importance, and had no advantages of position. It was destroyed by Gelon about 451 B.C., and its walls seem to have been razed to the ground. In the Athenian expedition against Syracuse (415-413) Lamachus proposed (it being then deserted) to make it the Athenian base of operations; but his advice was not taken, and in the next spring the Syracusans fortified it. In 396 it was still fortified; but, after Marcellus captured it, in 214, we hear little more of it. Excavations carried on in 1891 led to the discovery of the
northern portion of the western town wall, which in one section
served at the same time as an embankment against floods
(it was apparently more conspicuous in the time of P. Cluver,
Sicilia, p. 133), of an extensive necropolis, about 1000 tombs
of which have been explored, and of a deposit of votive objects
from a temple. The harbour lay to the north of the town.

See P. Orsì in Monumenti dei Lincei (1891), i. 686–950; and Atti
del congresso delle scienze storiche, v. 181 (Rome, 1904). (T. A.S.)

MEGARIAN SCHOOL OF PHILOSOPHY. This school was
founded by Euclides of Megara, one of the pupils of Socrates. Two main
elements went to make up the Megarian doctrine. Like the Cynics and the
Cyrenaics, Euclides started from the Socratic principle that virtue is know-
ledge. But into combination with this he brought the Eleatic doctrine of Unity.
Perceiving the difficulty of the Socratic dictum he endeavoured to give to the
word knowledge a definite content by divorcing it absolutely from the sphere
of sense and experience, and confining it to a sort of transcendental dialectic or
logic. The Eleatic unity is Goodness, and is beyond the sphere of sensible
apprehension. This goodness, therefore, alone exists; matter, motion, growth
and decay are figments of the senses; they have no existence for Reason.
Whatever is, is! Knowledge is of ideas and is in conformity with the
necessary laws of thought. Hence Plato
in the Sophist describes the Megarians as "the friends of ideas." Yet the
Megarians were by no means in agreement with the Platonic
idealism. For they held that ideas, though eternal and im-
memorable, have neither life nor action nor movement.

This dialectic, initiated by Euclides, became more and more
opposed to the testimony of experience; in the hands of Eubulides and
Alexinus it degenerated into hair-splitting, mainly in the
form of the reductio ad absurdum. The strength of these men
lay in destructive criticism rather than in construction: as
dialecticians they were successful, but they contributed little
to ethical speculation. They spent their energy in attacking
Plato and Aristotle, and hence earned the opprobrious epithet of
Eristic. They used their dialectic subtlety to disprove
the possibility of motion and decay; unity is the negation of
change, increase and decrease, birth and death. None the less,
in ancient times they received great respect owing to their
intellectual pre-eminence. Cicero (Academica, i. 43) describes their doctrine as a "nobilis disciplina," and identifies them
closely with Parmenides and Zeno. But their most immediate in-
fluence was upon the Stoics (q.v.), whose founder, Zeno, studied
under Strokomedes at Megara, and of striking and attractive
personality, succeeded in fusing the Megarian dialectic with
Cynic naturalism. The result of the combination was in fact
a juxtaposition rather than a compound; it is manifestly im-
possible to find an organic connexion between a practical code
like Cynicism and the transcendental logic of the Megarians.
But it served as a powerful stimulus to Zeno, who by descent
was imbued with oriental mysticism.

MEGARON, the principal hall of the ancient Greek palace,
situated in the andron or men's quarter. Examples have
been found at Tiryns and Mycenae, and references are made
to it in the Iliad and the Odyssey.

MEGATHERIUM (properly Megalotherium), a huge extinct
dentate mammal from the Pleistocene deposits of Buenos
Aires, typifying the family Megatheriidae (or Megalotheriidae),
and by far the largest representative of the Edentata. Except,
indeed, for its relatively shorter limbs Megatherium americanum
rivalled an elephant in bulk, the total length of the skeleton
being 18 feet, five of which are taken up by the tail. The
Megatheriidae, which include a number of genera, are collectively

FIG. 1.—Skeleton of the Megatherium, from the specimen in the Museum of the Royal
College of Surgeons of England.

In form, as shown in fig. 2, the teeth are
quadrangular prisms, each of which is
surmounted by a pair of transverse ridges.
They grew apparently throughout life,
and were implanted to a great depth in the
jaws, being 7 or 8 in: in length, with a
cross-section of at least an inch and a
half. The ridges on the crown are due
to the arrangement of the vertical layers
of hard dentine (fig. 3, a), softer vaso-

dentine (c) and cement (c). The skull
is relatively small, with the lower jaw
very deep in its central portion, and
produced in part into a long snout-like
symphysis for the reception, doubtless,
of a large and fleshy tongue (fig. 2).
Unlike sloths, the megatherium has seven
cervical vertebrae; and the spines of all
the trunk-vertebrae incline backwards.
The pelvis and hind-limbs are much
more powerful than the fore-quarters;
thereby enabling these animals, in all
probability, to rear themselves on their
hind-quarters, and thus pull down the
branches of trees: if not, indeed, in some
cases to bodily uproot the trees them-
theselves. Large chevron-bones are sus-
pected to the verterebræ of the tail,
which was massive, and probably afforded a support when the
monster was sitting up. The humerus has no foramina, and the

Fig. 2.—Lower Jaw and Teeth of Megatherium.

(From Owen.)
MEGHNA—MEHEMET ALI

whole fore-limb was very mobile. The first front toe was rudimentary, having no phalanges, but the fifth was rather less aborted, although clawless; the other three carried enormous claws, protected by reflected sheaths. The hind-foot is remarkable for the great backward projection of the calcaneum, and likewise for the peculiar shape of the astragalus; the middle toe alone carries a claw, this being of huge size, and ensheathed like those of the fore foot. No trace of a bony armour in the skin has been detected; but, from the evidence of other genera, it may be assumed that the body was clothed in a coat of long, coarse hair. Although similar teeth occur in the phosphorite beds of South Carolina, which may have been transported from elsewhere, no undoubted remains of Megatherium are known from North America. The typical species ranged from Argentina and Chili to Brazil. For certain small ground-sloths from Patagonia with Megatherium-like teeth, see Mylodon.

MEGHNA, a river of India. It forms, in the lower part of its course, the great estuary of the Bengal delta, which conveys to the sea the main body of the waters of the Ganges and the Brahmaputra, which unite at Goaland in Faridpur district. The united waters, turbid and of great depth, are sometimes split into half a dozen channels by sand-banks, sometimes spread into a wide sheet of water. The river enters the sea by four principal mouths, enclosing the three large islands of Dakshin Shahbazpur, Hatia and Sandwip. It is navigable by native boats and river steamers all the year; but the navigation is difficult and sometimes dangerous on account of shifting sand-banks and snags, and boisterous weather when the monsoon is blowing. The most favourable season is between November and February. Alluvion and diluvion are constantly taking place, especially along the seaboard, and in Noakhali district the land is said to have made rapid advance on the sea; while the islands fringing the mouth are annually being cut away and redeposited in fresh shapes. The regular rise of the tide is from 10 to 18 ft., and at springs the sea rushes up in a dangerous bore. It is greatest at the time of the biennial equinoxes, when navigation is sometimes impeded for days together. The tidal wave advances like a wall topped with foam of the height of nearly 20 ft., and at the rate of 15 m. an hour; in a few minutes it is past, and the river has changed from ebb to flood tide. A still greater danger is the "storm wave" which occasionally sweeps up the Meghna under a cyclone.

MEHADIA, a market town of Hungary, in the county of Krassó-Szörény, 287 m. S.E. of Budapest by rail. Pop. (1900), 2402. The town is the site of the ancient Roman colony Ad Mediam, near which passed the Roman road from the Danube to Dacia. It contains the ruins of a fortress, and other Roman remains. In its neighbourhood are the famous Hercules baths (Hungarian, Herkulesfürdő). These are situated in a narrow rocky ravine in the valley of the Cserna, where there are 22 hot springs, of which nine are in use, the most powerful being the Hercules spring. The springs are all strongly impregnated with salts of sulphur, iodine, bromine and chlorine, and their average temperature is 75° to 145° F. They were famous in the Roman period under the name of Thermae Hercules or Fontes Hercules. Their popularity is attested by numerous inscriptions and relics. After the fall of the Roman Empire they fell into disuse until 1735, but in modern times they have been much frequented.

MEHEMET ALI (1769—1849), pasha and afterwards viceroy of Egypt, was born at Kavala, a small seaport on the frontier of Thrace and Macedonia. His father, an Albanian, was a zada, a small yeoman farmer, and he himself lived in his native town for many years as a petty official and trader in tobacco. In 1798 he became second in command of a regiment of bashi-bazouks, or volunteers, recruited in his neighbourhood to serve against Napoleon in Egypt. He took part in the battle of Aboukir (July 25, 1799), was driven into the sea with the routed Turks, and was saved from drowning by the gig of the British admiral, Sir Sidney Smith. In 1801 he returned to Egypt, in command of his regiment, and on the 9th of May distinguished himself by heading a bold cavalry charge at the battle of Rahmanieh. In the troubled years that followed, Mehemet Ali, leader of a conspiracy of Albanian clansmen, was in the position to draw advantage from the struggle for power between the Mamelukes and the representatives of the Porte. In 1803 he cast in his lot with the former; in 1804 he turned against them and proclaimed his loyalty to the sultan; in 1805 the sheiks of Cairo, in the hope of putting a stop to the intolerable anarchy, elected him pasha, and a year later an imperial firman confirmed their choice. The disastrous British expedition of 1807 followed; and while at Constantinople the prestige of the sultan was being undermined by the series of revolutions which in 1808 brought Mahmut II. to the throne, that of Mehemet Ali was enhanced by the exhibition at Cairo of British prisoners and an avenue of stakes decorated with the heads of British slain.

The situation revealed to the astute Albanian boundless possibilities for gratifying his ambition. In spite of his chance victories, he was too shrewd an observer not to recognize the superiority of European methods of warfare; and as the first step towards the empire of which he dreamed he determined to create an army in the European model. In 1808 the building and organization of the navy was begun with the aid of French officers and engineers. In 1811 the massacre of the Mamelukes left Mehemet Ali without a rival in Egypt, while the foundations of his empire beyond were laid by the war against the Wahhabis and the conquest of the holy cities of Mecca and Medina. The Wahhabi War, indeed, dragged on till 1818, when Ibrahim (q.v.), the pasha's son, who in 1816 had driven the remnant of the Mamelukes into Nubia, brought it to an end. This done, the pasha turned his attention southward to the vast country watered by the Upper Nile. In 1820 the oasis of Siwa was subdued by his arms; in 1823 he laid the foundations of Khartum.

By this time Mehemet Ali was the possessor of a powerful fleet and of an army of veterans disciplined and drilled by European officers. To obtain these money had been necessary; and to raise money the pasha had instituted those internal reforms—the bizarre system of state monopolies and the showy experiments in new native industries which are described in the article Egypt (q.v.). The inherent viciousness of these expedients had, however, not as yet been revealed by their inevitable results, and Mehemet Ali in the eyes of the world was at once the most enlightened and the most powerful of the sultan's vails. To Mahmud II., whose whole policy was directed to strengthening the authority of the central power, this fact would have sufficed to make him distrust the pasha and desire his overthrow; and it was sorely against his will that, in 1822, the ill-success of his arms against the insurgent Greeks forced him to summon Mehemet Ali to his aid. The immediate price was the pashalik of Crete; in the event of the victory of the Egyptian arms the pashaliks of Syria and Damascus were to fall to Mehemet Ali, that of the Morea to his son Ibrahim. The part played by Mehemet Ali in the Greek War is described elsewhere (see TURKEY: History; GREECE: History; GREEK INDEPENDENCE, WAR OF;
Ibrahim. The intervention of the powers, culminating in the shattering of the Egyptian fleet at Navarino (q.v.), robbed him of his reward so far as Greece was concerned; the failure of his arms in face of this intervention gave Sultan Mahmud the excuse he desired for withholding the rest of the stipulated price of his assistance.

This disappointment of his ambition would not perhaps in itself have sufficed to stir Mehemet Ali to revolt against his master; but it was ominous of perils to come, which the astute pasha thought it wise to forestall. The sultan's policy had been consistently directed to crushing the overgrown power of his vassals; in the spring of 1831 two rebellious pashas, Hussein of Bosnia and Mustafa of Scutari, had succumbed to his arms; and, since he was surrounded and counselled by the personal enemies of the pasha of Egypt, it was likely that, so soon as he should feel himself strong enough, he would deal in like manner with Mehemet Ali. It was to anticipate this peril that Mehemet Ali determined himself to open the struggle: on the 1st of November 1831 a force of 9,000 Egyptian infantry and 2,000 cavalry crossed the frontier into Syria and met at Jaffa the fleet which Ibrahim had brought to Genoese-in-chief. The combined forces at once laid siege to St Jean d'Acre.

The stubborn resistance of the garrison delayed Ibrahim's progress; and, meanwhile, wild rumours went abroad as to Mehemet Ali's intentions. He was master of the holy cities, and the official Moniteur Ottoman denounced his supposed plan of aiming at the caliphate in collusion with the sherif of Mecca. As for the pasha himself, he loudly disclaimed any such disloyal pretensions; his aim was to chastise Abdulla, pasha of Acre, who had harboured refugees from his reforms; to overthrow Khusrev, who had encouraged him in his refusal to surrender them; to secure the fulfilment of the sultan's promise with regard to Syria and Damascus. Mahmud, on the other hand, was torn between hatred of the pasha and hatred of the Christian powers which had forced him to make concessions to the Greeks. Voices urged him to come to terms with Mehemet Ali, secure peace in Islam, and turn a united face of defiance against Europe; and for a while he harboured the idea. He was conscious of his own intense unpopularity, the outcome of his efforts at reform; he knew that in popular opinion Mehemet Ali was the champion of Islam against the infidel caliph, and that the issue of a struggle with him was more than doubtful. He was hampered by the unpaid debt to Russia; by unrest in Bosnia and Albania; above all, by the revolt of the Greek Islands, which had left his navy, deprived of its best sailors, in no condition to dispute the Egyptian command of the sea. In the end, however, his pride prevailed; in April 1833 the Turkish commander-in-chief Hussein Pasha left Constantinople for the front; and in the third week in May the ban of outlawry was launched against Mehemet Ali.

Meanwhile, Ibrahim had occupied Gaza and Jerusalem as well as Jaffa; on the 27th of May, a few days after the publication of the ban, Acre was stormed; on the 15th of June the Egyptians occupied Damascus. Ibrahim pressed on with characteristic rapidity, his rapid advance being favoured by the friendly attitude of the various sections of the Syrian population, whom he had at pains to conciliate. He defeated the Ottoman advance-guard at Hom on the 9th of July and at Hamah on the 11th, entered Aleppo on the 17th, and on the 20th inflicted a crushing defeat on the main Turkish army under Hussein Pasha at the pass of Beilan. All Syria was lost to the sultan, and the Egyptian advance-guard passed the mountain defiles into Adana in Asia Minor.

Mahmud, in desperation, now turned for help to the powers. Russian aid, though promptly offered, was too double-edged a weapon to be used save at the last extremity. Austrian diplomacy was, for the moment, that of Russia. France had broken her long tradition of friendship for Turkey by the occupation of Algiers. Great Britain, prodigal of protestations of goodwill, alone remained; and to her Mahmud turned with a definite offer of an offensive and defensive alliance. Stratford Canning, who was at Constantinople for the purpose of superintending the negotiations for the delimitation of the frontiers of Greece, wrote home urging the government to accept, and suggesting a settlement of the Egyptian question which foreshadowed that of 1841. Palmerston, however, did not share Canning's belief in the possible regeneration of Turkey; he held that an isolated intervention of Great Britain would mortalily offend not only Russia but France, and that Mehemet Ali, disappointed of his ambitions, would find in France a support that would make him doubly dangerous.

In the autumn Sultan Mahmud, as a last independent effort, despatched against Ibrahim the army which, under Reshid Pasha, had been engaged in pacifying Albania. The result was the crowning victory of the Egyptians at Konia (Dec. 21). The news reached Constantinople at the same time as Count Muravieff arrived on a special mission from the tsar. The Russian offers were at once renewed of a squadron of battleships and of a land force for the protection of the capital. Efforts were made to escape the necessity of accepting the perilous aid. Ottoman agents, backed by letters from the French chargé d'affaires, were sent to Mehemet Ali and to Ibrahim, to point out the imminence of Russian intervention and to offer modified terms. Muravieff himself went to Alexandria, where, backed by the Austrian agent, Count Prokofiev-Ostien, he announced to the pasha the tsar's immutable hatred of rebels. Mehemet Ali merely protested the complete loyalty of his intentions; Ibrahim, declaring that as a soldier he had no choice but to obey his father's orders, advanced to Afim-Karahissar and Kuitaia, whence he wrote to the sultan asking his gracious permission to advance to Brusa. He was at the head of 100,000 men, well organized and flushed with victory; the Ottoman army survived only as demoralized rabble. Panic seized the Seraglio; and at the beginning of February the assistance of Russia was formally demanded. The representatives of France and Great Britain made every effort to secure a reversal of this fatal step; but, while they were threatening and promising, Russia was acting, and on the 20th of February a Russian squadron entered the Bosphorus.

In view of this it became necessary for the objecting powers to take a new line. The new French ambassador, Admiral Roussin, was received on the 17th; he now, with the full concurrence of Canning, obtained from Lord Castlereagh the British chargé d'affaires, persuaded the Porte to invite the Russians to withdraw, undertaking that France would secure the acceptance by Mehemet Ali of the sultan's terms. A period of suspense followed. The Russian squadron was detained by contrary winds, and before it could sail peremptory orders arrived from the tsar for it to remain until Ibrahim should have repassed the Taurus mountains. Meanwhile, Mehemet Ali had scornfully rejected the offers of the Porte; he would be content with nothing but the concession of his full demands—Syria, Icheli, Aleppo, Damascus and Adana. France and Great Britain now urged the sultan to yield, and in March a Turkish agent was sent to Ibrahim to offer the pashaliks of Syria, Aleppo and Damascus. The crisis was precipitated by the arrival on the 5th of April of a second division of the Russian fleet in the Bosphorus, and of a Russian force of 6,000 men, which landed on the Asiatic shore. The Porte now tried once more to modify its terms; but the Western powers were now intent on getting rid of the Russians at all costs, and as a result of the pressure they brought to bear on both parties the preliminary convention of Kuitaia, conceding all the Egyptian demands, was signed on the 8th of April, and Ibrahim began his withdrawal. The convention stipulated for the bestowal of the pashalik of Adana on Ibrahim; but when on the 16th he received the official list of appointments, he found that Adana had been expressly reserved by the sultan. He at once arrested his march; but the pressure of famine in the capital, caused by the cutting off of supplies from Asia and the presence of the large Russian force, compelled Mahmud to yield, and on the 3rd of May a firman ceded Adana to Ibrahim under the pretext of appointing him mulassil, or collector of the revenue.

When Lord Ponsonby, the new British ambassador, arrived at

1 Canning's original memorandum is in the Foreign Office Records in the volume marked F.O., Turkey: From Sir Stratford Canning (August to December, 1832). It bears elaborate pencil notes in Palmerston's handwriting, in part already obliterated.
Mehemet Ali was now absolute master of the situation. The grand vizier, in the sultan’s name, wrote beseeching him to avoid the further shedding of Mussulman blood, offering him a free pardon, the highest honours of the state, the hereditary pashalik of Egypt for himself, and Syria for Ibrahim until he should succeed his father in Egypt. Mehemet Ali replied diplomatically; for, though these offers fell far short of his ambitions, a studious moderation was essential in view of the doubtful attitude of the European powers.

On the 27th of July the ambassadors of the five powers presented to the Porte a joint note, in which they declared that an agreement on the Eastern Question had been reached by the five Great Powers, and urged it “to suspend all definite decision made without their concurrence, pending the effect of their interest in its welfare.” The necessity for showing a united front justified the diplomatic inexactitude; but the powers were agreed on little except the need for agreement. Especially was this need realized by the British government, which feared that Russia would seize the occasion for an isolated intervention under the treaty of Unkia Skelessi. On the 1st of August Palmerston wrote to Ponsonby impressing upon him that the representatives of the powers, in their communications with the Porte, “should act not only simultaneously in point of time, but identically in point of manner”—a principle important in view of later developments. Yet it was a task all but impossible to preserve this appearance of unanimity in view of the divergent views within the concert. France and Great Britain had hitherto acted together through common opposition to the supposed designs of Russia. Austria, too, now that the revolutionary spectres of 1830 had been laid, was reverting to her traditional opposition to Russia in the affairs of the Near East, and Metternich supported Palmerston’s proposal of an international conference at Vienna. Everything depended on the attitude of the emperor Nicholas. This was ultimately determined by his growing disposition to destroy his superiority in the field; the commercial treaty signed by the Ottoman government with Great Britain (Aug. 15), which applied equally to all the territories under his rule, threatened to destroy at a blow the lucrative monopolies which supplied him with the sinews of war. Months of suspense followed; for the powers had threatened to cast their weight into the scale against whichever side should prove the aggressor, and Mehemet Ali was too astute to make the first move. In the end Mahmud’s passion played into his hands. The old sultan thirsted to crush his rebellious vassal, at any cost; and on the 1st of July 1839 the Ottoman army, stationed at Bir on the Euphrates, crossed the stream and invaded Syria. On the 3rd of June it was attacked and utterly routed by Ibrahim at Nezib. On the 1st of July the old sultan died, unconscious of the fatal news, leaving his throne to Abdul-Mejid, a lad of sixteen. To complete the desperation of the situation the news reached the capital that Ahmed Pasha, the Ottoman admiral-in-chief, had sailed to Alexandria and surrendered his fleet to Mehemet Ali, on the pretext that the sultan’s advisers were sold to the Russians.

So far as the forces of the Ottoman Empire were concerned, 

From Lord Ponsonby, F.O., Turkey, May 22, 1833.
Egypt, a proposition to which Palmerston, though sincerely anxious to preserve the Anglo-French entente, refused to agree. The cabinet of Thiers at last fell on the 27th of July, 1839, and on the 15th of September, Suleiman Pasha not having obeyed the summons to evacuate the town, the bombardment was begun, and Ottoman troops were landed to co-operate with the rebels. On the 3rd of October Beirut fell; and Ibrahim, cut off from his communications by sea, and surrounded by a hostile population, began a hurried retreat southward. On the 3rd of November Acre surrendered to the allied fleet. Mehemet Ali’s power in Syria had collapsed like a pricked bubble; and with it had gone for ever the myth of his humane and enlightened rule. The sole question now was whether he should be allowed to retain Egypt itself.

On the 15th of September the sultan, who had broken off all negotiations with Mehemet Ali on receipt of the news of the Syrian revolt, acting on the advice of Lord Ponsonby, declared the pasha deposed, on the ground that the term allowed by the Convention of London had expired, and nominated his successor. Mehemet Ali received the news with his accustomed sang-froid, observing to the consuls of the four powers, who had come to notify their own removal, that “such denunciations were nothing new to him; that this was the fourth, and that he hoped to get over it as well as he had done the other three, with the help of God and the Prophet.” In the end his confidence proved to be justified. The news of the events in Syria and especially of the deprivation of Mehemet Ali had produced in France what appeared to be an exceedingly dangerous temper; the French government declared that it regarded the maintenance of Mehemet Ali in Egypt as essential to the European balance of power; and Louis Philippe sought to make it clear to the British government, through the King of the Belgians, that, whatever might be his own desire to maintain peace, in certain events to do so would be to risk his throne. Palmerston, indeed, who did not believe that under the Bourgeois Monarchy France would translate her brave words into action, was in favour of settling the Turco-Egyptian question once for all by depriving Mehemet Ali of Egypt as well. The influences against him, however, were too powerful. It was apprehended that a change of the sultan of Egypt would be followed by a change of the sultan of Turkey, and that this would produce as a result, in his opinion, either in a war or a revolution in France; King Leopold enlarged on the wickedness and absurdity of risking a European war for the sake of putting an end to the power of an old man who could have but few years to live; Queen Victoria urged her ministers to come to terms with France and relieve the embarrassments of the “dear King”; and Lord Melbourne, with the majority of the cabinet, was in favour of compromise. When therefore, on the 8th of October, Guizot, in an interview with Palmerston, presented what was practically an ultimatum on the part of France, “it was determined that this intimidation should be met in a friendly spirit, and that Lord Palmerston should see the Ministers of the other powers and agree with them to acquaint the French that they with England would use their good offices to induce the Porte not to insist on the deprivation of Mehemet Ali so far as Egypt is concerned.” In accordance with this Palmerston instructed Ponsonby to press the Sultan to do away with the title of Mehemet Ali’s speedy submission, not only to withdraw the sentence of deprivation but to confer upon him the hereditary pashalik of Egypt.

For a while it seemed that even this would not avert a European war. Thiers still maintained his warlike tone, and the king’s speech prepared by him for the opening of the Chambers on the 28th of October was in effect a declaration of defiance to Europe. Louis Philippe himself, however, was not prepared to use this language; whereupon Thiers resigned, and a new cabinet was formed under Marshal Soult, with Guizot as foreign secretary. The equivocal tone of the new speech from the Throne raised a storm of protest in the Chambers and the country. It was, however, soon clear that Palmerston’s diagnosis of the temper of the French bourgeois was correct; the clamour for war subsided; on the 4th of December the address on the Egyptian Question proposed by the government was carried, and peace was assured. Nine days earlier Sir Charles Napier had appeared with the British squadron off Alexandria and, partly by persuasion, partly by threats, had induced Mehemet Ali to submit to the sultan and to send back the Ottoman fleet, in return for a guarantee
of the hereditary pashalik of Egypt. This arrangement was ratified by Palmerston; and all four powers now combined to press on on the reluctant Porte, pointing out, in a joint note of the 30th of January 1841, that "they were not conscious of advising a course out of harmony with the sovereignty and legitimate rights of the sultan, or contrary to the duties imposed on the Pasha of Egypt as a subject appointed by His Highness to govern a province of the Ottoman Empire." This principle was elaborated in the firman, issued on the 13th of February, by which the sultan conferred on Mehmet Ali and his heirs by direct descent the pashalik of Egypt, the greatest care being taken not to bestow any rank and authority greater than that enjoyed by other viziers of the empire. By a second firman of the same date Mehmet Ali was invested with the government of Nubia, Darfur, Khordofan and Sennaar, with their dependencies. On the 10th of June the firman was solemnly promulgated at Alexandria.

Thus ended the phase of the Egyptian Question with which the name of Mehmet Ali is specially bound up. The threatened European conflict had been averted, and presently the wounded susceptibilities of France were healed by the invitation extended to her to take part in the Suez Convention. As for Mehmet Ali himself, he now passes off the stage of history. He was an old man; his mind was soon to give way; and for some time before his death on the 2nd of August 1840 the reins of power were held by his son and successor Ibrahim.

Probably no Oriental ruler, not even excepting Ali of Iannina, has ever stirred up so much interest among his contemporaries as Mehmet Ali. The spectacle of an Eastern despot apparently advancing on the lines of European progress was in itself as astonishing as new. Men thought they were witnessing the dawn of a new era in the East; Mehmet Ali was hailed as the most beneficent and enlightened of princes; and political philosophers like Jeremy Bentham, who sent him elaborate letters of good advice, thought to find in him the means for developing their theories in virgin soil. In fact the pasha was an illiterate barbarian, of the same type as his countryman Ali of Iannina, courageous, cruel, astute, full of wiles, avaricious and boundlessly ambitious. He never learned to read or write, though late in life he mastered colloquial Arabic; yet those Europeans who were brought into contact with him praised alike the dignity and charm of his address, his ready wit, and the astonishing perspicacity which enabled him to read the motives of men and of governments and to deal effectively with each situation as it arose.

The latest account of Mehmet Ali and the European crisis arising out of his revolt is by W. Alison Phillips in vol. x. ch. xvii. of the Cambridge Modern History (1907). The bibliography attached to this chapter (p. 852) gives a list of all the principal publications on his career, and works, together with some analysis of the unpublished Foreign Office records bearing on the subject. Of the works mentioned C. de Freycinet's La Question d'Egypte (Paris, 1895) gives the most authoritative account of the diplomatic developments.

MEHPUR, or MAHIPUR, a town of India, in Indore state of Central India, on the right bank of the Sira, 1543 ft. above the sea, and 24 m. N. of Ujain. Pop. (1901), 6681. Though of some antiquity and frequented by Hindu pilgrims it is best known for the battle fought in the neighbourhood on the 20th of December 1877, in which Sir John Malcolm defeated the army of Holkar. The result was the Treaty of Mandasor and the pacification of Malwa. Mehipur was again the scene of some sharp fighting during the Mutiny. The British cantonment, placed here in 1877, was removed in 1882.

MÉHUL, ÉTIENNE HENRI (or ÉTENNE NICOLAS) (1763–1817), French composer, was born at Givet in Ardennes, on the 24th of June 1763. His father being too poor to give him a regular musical education, his first ideas of art were derived from a poor blind organist of Givet; yet such was his aptitude that, when ten years old, he was appointed organist of the convent of the Récollets. In 1775 an able German musician and organist, Wilhelm Hauser, was engaged for the monastery of Lavaldieu, a few miles from Givet, and Méhul became his occasional pupil. In 1778 he was taken to Paris by a military officer, and placed himself under Edelmann, a good musician and harpsichord player. His first attempts at instrumental composition in 1781 did not succeed, and he therefore turned his attention to sacred and dramatic music. Gluck gave him advice in his studies. After various disappointments during his efforts for six years to obtain, at the Grand Opéra, a representation of his Cora et Alonso, he offered to the Opéra Comique his Euphoriste et Coradin, which, being accepted and performed in 1790, at once fixed his reputation. His opera of Stratonice was also received with enthusiasm in 1792. After several unsuccessful operas, his Adrien appeared, and added much to his fame, which was further increased by his three best works, Le Jeune Henri, Uthal and Joseph, the finest of the series. Uthal was written for an orchestra without violins. Méhul held a post as one of the four inspectors of the Paris Conservatoire, but this office made him feel continually the insufficiency of his early studies, a want which he endeavoured to remedy by incessant application. Timoleon, Ariodan and Bion followed. Épicure was composed by Méhul and Cherubini jointly; but the superiority of the latter was evident. Méhul's next opera, L'Iratte, failed. After writing forty-two operas, besides a number of songs for the festivals of the republic, cantatas, and orchestral pieces of various kinds, his health gave way, from an affection of the chest, and he died on the 18th of October 1817 in Paris.

See Lives by Pougin (1880), Viellard (1850), and Quatremère de Quincy (1818).

MEIBOM, HEINRICH (1555–1629), German historian and poet, was born at Lemgo on the 4th of December 1555, and died on the 20th of September 1625, at Helmstedt, where he had held the chair of history and poetry since 1583. He was a writer of Latin verses (Paradiorum horatariorum libri III. et sybarum libri II., 1588); and his talents in this direction were recognized by the emperor Rudolph II., who ennobled him; but his claim to be remembered rests on his services in elucidating the medieval history of Germany.

His Opuscula historic a ad germanicarum spectacula was edited and published in 1677 by his grandson, Heinrich Meibom (1628–1700), who was professor of medicine and then of history and poetry at Helmstedt, and incorporated his grandfather's work with his own Rerum germanicarum scrip toribus (1688).

MEIDERICH, a town of Germany, in the Prussian Rhine province, 2½ m. by rail N.E. of Ruhrot, whose river harbour is in great part within its confines. Pop. (1905), 40,822. Iron and steel works, coal-mines, saw-mills, brickworks, and machine-shops furnish the principal occupations of the inhabitants. Meiderich, which is first mentioned in 874, was united with Duisburg in 1905.

See Graebner, Tausendjährige Geschichte von Meiderich (1893).

MEIKTLA, a district and division in Upper Burma. The district is the most easterly of the districts in the dry zone, and has an area of 2183 sq. m. It lies between Kyauksé, Myingyan, Yamethin, and on the east touches the Shan States. It is a slightly undulating plain, the gentle slopes of which are composed of black "cotton" soil and are somewhat arid. The only hills above 300 ft. are on the slopes of the Shan hills. The lake is the chief feature of the district. It is artificial, and according to Burmese legend was begun 2400 years ago by the grandfather of Gautama Buddha. It is 7 m. long, averages half a mile broad, and covers an area of 3½ sq. m. With the Minhla and other connected lakes it irrigates a large extent of country.

There are small forest reserves, chiefly of cutch. Large numbers of cattle are bred. The chief agricultural products are rice, sesame, cotton, peas, maize, millet and gram. Pop. (1901), 252,305. Famines in 1801, 1805 and 1856 led to considerable emigration. The climate is healthy except in the submontane townships. The temperature rises to 106° F. and over between the months of March and June, and the mean minimum in January is about 61°. The rainfall is uncertain (36-79 in. in 1893, 25-59 in. 1891). The vast majority
MEILHAC—MEIR OF ROTHERBURG

83

of the population are Buddhists. The headquarters town, MEIKTLA, stands on the banks of the lake, which supplies good drinking water. Pop. (1901), 7,203. A wing of a British regiment is stationed here. A branch railway connects it at Thazi station with the Rangoon-Mandalay line, and continues westward to its terminus on the Irrawaddy at Myingan.

The division includes the districts of Meiktila, Kyaukse, Yamethin, and Mingyan, with a total area of 10,852 sq. m., and a population (1901) of 992,807, showing an increase of 10.2% in the preceding decade, and giving a density of 97 inhabitants to the square mile. All but a small portion of the division lies in the dry zone, and cultivation is mainly dependent on irrigation.

MEILHAC, HENRI (1831-1897), French dramatist, was born in Paris on the 21st of February 1831, and while a young man began writing fanciful articles for the newspapers and vaudevilles for the theatres, in a vivacious boulevardier spirit which brought him to the front. About 1860 he met Ludovic Halévy, and the two began a collaboration in writing for the stage which lasted for twenty years. An account of their work is given under HALÉVY. Meilhac wrote a few pieces with lesser collaborators. In 1888 he was elected to the Academy. He died in Paris in 1897.

MEINBERG, a village and watering-place of Germany, in the principality of Lippe-Detmold, situated in a pleasant valley under the Hardt, and about 120 m. S.E. of Detmold by the railway to Altenbeken. Pop. (1895), 1,350. The waters of Meinberg, which attract annually about 1,200 visitors, are sulphur springs, and are used for drinking, bathing and inhalation. They became known in the 18th century. See Gilbert and Meissner, Bad Meinberg and seine Kurmittel (Berlin, 1902).

MEINEKE, JOHANN ALBRECHT FRIDRICH AUGUST (1790-1870), German classical scholar, was born at Soest in Westphalia on the 8th of December 1790. After holding educational posts at Jenkau and Danzig, he was director of the Joachimsthal gymnasium in Berlin from 1826 to 1836. He died at Berlin on the 12th of December 1870. He was distinguished in critical, historical and philological studies, and especially in edited works and writings of the most ancient writers, being his favourite authors.

His most important works are: Creecorum comicerum fragmenta (1839-1857), the first volume of which contains an essay on the development of Greek comedy and an account of its chief representatives, Aristophanes (1860); Anastasius alexandrinus (1843, containing the fragments of Rhianus, Euphorion, Alexander of Aetolia, and Parthenius); Callimachus (1861); Theocritus, Bion, Moschus (3rd ed., 1850); Alciphron (1853); Strabo (2nd ed., 1866) and Pliny (1862); Corpus Iudaeorum (1855-1858); and Seemorgaphia (1858-1867). See monographs by F. Ranke (1871), H. Sauppe (1872), and E. Förstemann in Allgemeine deutsche Biographie, XXI, (1885); also Sandys, Hist. Class. Schol. (1906), iii. 117.

MEININGEN, a town of Germany, capital of the duchy of Saxe-Meiningen, romantically situated in forests on the right bank of the Werra, 40 m. S. of Eisenach by rail. Pop. (1905), 15,989. It consists of an old town and several modern suburbs, but much of the former has been rebuilt since a fire in 1874. The chief building is the Elisabethenborg, or the old ducal palace, containing several collections; it was built mainly about 1680, although part of it is much older. Other buildings are the henneberger Haus with a collection of antiquities, and the town church, with twin towers, built by the emperor Henry II. in the 11th century. The theatre enjoyed for many years (1875-1890) a European reputation for its actors and scenic effects. The English garden, a beautiful public park, contains the ducal mortuary chapel and several monuments, including busts of Braums and Jean Paul Richter. Meiningen, which was subject to the bishop of Würzburg (1046), came into the possession of the duchy of Saxony in 1583, having in the meantime belonged to the counts of Henneberg. At the partition of 1660 it fell to the share of Saxe-Altenburg, and in 1680 became the capital of Saxe-Meiningen.

See E. Dähner, BauwRUNEN und Wallau der Stadt Meiningen (Meiningen, 1902).

MEIR, Jewish rabbi of the 2nd century, was born in Asia Minor and according to legend was a descendant of the family of Nero. He was the most notable of the disciples of Agiba (q.v.), and after the Hadrianic repressions of A.D. 135 was instrumental in refunding the Palestinian schools at Usha. Among his teachers was also Eliezer ben Abuya (q.v.), and, Meir continued his devotion to Elisha after the latter's apostasy. He is said to have visited Rome to rescue his wife's sister. His wife, Beruriah, is often cited in the Talmud as an exemplar of generosity and faith. She was a daughter of the martyr Hananiah ben Teradion. On one occasion Meir, who had been frequently troubled by his ungodly neighbours, uttered a prayer for their conversion: "Almighty God," said Beruriah, "write (Ps. civ. 35) let sins be blotted out, not sinners"; whereupon Meir prayed for the evildoers' conversion. But she is best known for her conduct at the sudden death of her two sons. It was the Sabbath, and Meir returned home towards sunset. He repeatedly asked for the children, and Beruriah, after parrying his question, said: "Some time ago a precious thing was left with me on trust, and now the owner demands its return. Must I give it back?" "How can you question it?" rejoined his wife. Beruriah then led him to the bed whereon were stretched the bodies of the children. Meir burst into tears. But the wife explained that this was the treasure of which she had spoken, adding the text from Job: The water of life can be given only to the worthy. And indeed, the name of the Lord". Meir himself was the author of many famous sayings: "Look not to the flask, but to its contents. Many a new vessel contains old wine, but there are old casks which do not contain even new wine." "Condole not with a mourner while his dead is laid out before him." "Man cometh into the world with closed hands as though claiming the ownership of all things; but he departeth hence with hands open and limps, as if to show that he taketh naught with him." "What God does is well done." "The tree itself supplies the handle of the axe which cuts it down." His wisdom was proverbial, and to him was in particular assigned an intimate acquaintance with fox tales, and he is reported to have known 300 Fox-Fables. "With the death of Rabbi Meir," says the Mishnah (Sota iv. 15), "Fabulists ceased to be.

Meir's wide sympathies were shown in his inclusion of all mankind in the hopes of salvation (Sifra to Leviticus xviii. 5). He was certainly on friendly terms with heathen scholars. Meir contributed largely to the material from which finally emerged the Mishnah. His dialectic skill was excessive, and it was said jestingly of him that he could give 150 reasons to prove a thing clean, and as many more to prove it unclean. His balanced judgment fitted him to carry on Agiba's work, siting and arranging the oral traditions, and thus preparing the ground for the Mishnaic Code.

Meir left Palestine some time before his death, owing to disagreements between him and the Patriarch. He died in Asia Minor, but his love for the Holy Land remained dominant to the last. "Bury me," he said, "by the shore, so that the sea which washes the land of my fathers may touch also my bones." The tomb shown as that of Meir at Tiberias is inauthentic.

See Bachr, Agada der Tanaimen, vol. 11. ch. ii.; Graetz, History of the Jews (Eng. trans.), vol. 11. ch. xvi.; Jewish Encyclopedia (whence some of the above cited sayings are quoted), viii. 432-435. On Meir's place in the history of the Talmud see J. Jacob, The Life of Assop, i. 111, &c. (see Index s.v.).

MEIR OF ROTHERBURG (c. 1215-1293), German rabbi and poet, was born in Worms c. 1215. He played a great part in organizing the Jewish community of Worms. In 1227, for unknown reason he was thrown into prison in Alsace, where he remained until his death in 1293. His friends offered to find a ransom, but he declined the suggestion, fearing that the precedent would lead to extortion in other cases. He wrote glosses to the Talmud (tosephah) and many Responsa of the utmost value for historical research. Through his disciples Asher ben Yehiel and Mordecai ben Hillel, Meir exercised much
influence on subsequent developments of Judaism. He was also a liturgical poet of considerable merit. One of his finest elegies is translated into English in Nina Davis's *Songs of Exile*.

**MEIRINGEN,** the principal village on the Hasle (or the upper Aar) valley in the Swiss canton of Bern. It is built at a height of 1690 ft. on the right bank of the Aar and on the level floor of the valley, but is much exposed to the south wind (or Föhn), and has several times been in great part destroyed by fire (1632, 1879 and 1891). It has 3077 inhabitants, all German-speaking and Protestants. The parish church is ancient, and above it are the ruins of the medieval castle of Resti. Meiringen is frequented by tourists in summer, as it is the meeting-point of many routes: from Interlaken by the lake of Brienz and Brienz, from Lucerne by the Brünig railway (28 m.), from Engelberg by the Joch Pass (7267 ft.), from the upper Valais by the Grimsel Pass (7100 ft.), and from the Gotthard by the Great Schéidegg Pass (6434 ft.). Many waterfalls descend the hill-sides, the best known being the Reichenbach and the Alpbach, while the great gorge pierced by the Aar through the limestone barrier of the Kirchet is remarkable. The village and valley belonged of old to the emperor, who in 1324 gave the advowson to the Knights of St Lazarus, by whom it was sold in 1272 to the Austin Canons of Interlaken, on the suppression of whom in 1528 it passed to the state. In 1310 the emperor mortgaged the valley to the lords of Weissenburg, who sold it in 1334 to the town of Bern. (W. A. B. C.)

**MEISSEN,** a town of Germany, in the kingdom of Saxony, on both banks of the Elbe, 13 m. N.W. from Dresden, on the railway to Leipzig via Döbeln. Pop. (1905), 32,336. The old town lies on the left bank of the river, between the streams Meisse and Triebisch, and its irregular hilly site and numerous fine old buildings make it picturesque. Most of its streets are narrow and uneven. The cathedral, one of the finest early Gothic buildings in Germany, stands on the Schlossberg, 160 ft. above the town. It is said to have been founded by the emperor Otto the Great, but the present building was begun in the 13th century and was completed about 1450. Here are tombs of several rulers and princes of Saxony, including those of Albert and Ernest, the founders of the two existing branches of the Saxon house. The cathedral also contains works by Peter Vischer and Lucas Cranach and several other interesting monuments. A restoration, including the rebuilding of the two towers, was carried out in 1903-1908. Adjoining the cathedral is the castle, dating from 1471-1483, but restored and named the Albrechtsburg about 1766. Another restoration was undertaken about 1860, when a series of historical frescoes was painted upon its walls. A stone building of the 15th century connects the Schlossberg with the Afbarg, which owes its name to the old convent of St Afra. The convent was founded by Duke Maurice in 1543, and was by him converted into a school (the Fürsten Schule), one of the most renowned classical schools in Germany, which counts Lessing and Gellert among its former pupils. Other public buildings of interest are the town-hall, built in 1479 and restored in 1873; the fine town church, called the Frauenkirche or Marienkirche; the Nikolaikirche and the Afarkirche. The Franciscan church is now used as a museum of objects connected with the history of Meissen. Since 1710 Meissen has been the seat of the manufacture of Dresden china. Till 1860 the royal porcelain factory was in the Albrechtsburg, but in that year it was transferred to a large new building in the Triebischtal, near the town. Meissen also contains iron foundries, factories for making earthenware stoves and pottery, sugar refiners, breweries and canneries. A considerable trade is carried on in the wine produced in the surrounding vineyards, and other industries are spinning and weaving.

Meissen was founded about 920 by Henry the Fowler (see MEISSEN, Margravate). From 968 to 1581 Meissen was the seat of a line of bishops, who ranked as princes of the empire. During the 15th century the town suffered greatly from the Hussites, and it was captured by the imperial troops during the war of the league of Schmalkalden, and again in the Thirty Years War. In 1637 it suffered much from the Swedes, and in 1745 it fell into the hands of the Prussians. The bridge over the Elbe was destroyed by the French in 1813, and again by the Saxons in June 1866 in order to impede the march of the Prussians on Dresden. Cölln on the right bank of the Elbe was incorporated with Meissen in 1901.

**MEISSEN,** a German margravate now merged in the kingdom of Saxony. The mark of Meissen was originally a district centring round the castle of Meissen or Misnia on the Middle Elbe, which was built about 920 by the German king Henry I., the Fowler, as a defence against the Slavs. After the death of Gero, margrave of the Saxon east mark, in 965, his territory was divided into five marks, one of which was called Meissen. In 985 the emperor Otto III. bestowed the office of margrave on the margrave of Saxony, and the district comprising the marks of Meissen, Merseburg and Zeitz, which is now generally known as the mark of Meissen. In 1002 Eckard was succeeded by his brother Gunzelin, and then by his sons Hermann I. and Eckard II. Under these margraves the area of the mark was further increased, but when Eckard II. died in 1046 it was divided, and Meissen proper was given successively to William and Otto, counts of Weimar, and Egbert II., count of Brunswick. Egbert was a rival of the emperor Henry IV. and died under the imperial ban in 1048, when Meissen was bestowed upon Henry I., count of Wettin, whose mother was a sister of the margrave Eckard II. Henry, who already ruled lower Lusatia and the new and smaller Saxon east mark, was succeeded in 1103 by his cousin Thimo, and in 1104 by his son Henry II., whose claim on the mark was contested by Thimo's son Conrad. When Henry died without issue in 1123 Meissen was given by the emperor Henry III. to his son, the margrave of Wittenberg; but, renewing his claim, Conrad won the support of Lothair, duke of Saxony, afterwards the emperor Lothair II., and obtained possession in 1130. Conrad, called the Great, extended the boundaries of Meissen before abdicating in 1156 in favour of his son Otto, known as the Rich. Otto appointed his younger son Dietrich as his successor and was attacked and taken prisoner by his elder son Albert; but, after obtaining his release by order of the emperor Frederick I., he had only just renewed the war when he died in 1190. During his reign silver mines were opened in the Harz Mountains, towns were founded, roads were made, and the general condition of the country was improved. Otto was succeeded by his son Albert, called the Proud, who was engaged in warfare with his brother Dietrich until his death in 1195. As left no children, Meissen was seized by the emperor Henry VI. as vacant fief of the empire; but Dietrich, called the Oppressed, secured the mark after Henry's death in 1217. Dietrich married Jutta, daughter of Hermann I., landgrave of Thuringia, and was succeeded in 1221 by his infant son Henry, surnamed the Illustrious; who on arriving at maturity obtained as reward for supporting the emperor Frederick II. against the pope a promise to succeed his uncle, Henry Raspe IV., as landgrave of Thuringia. In 1243 Henry's son Albert was betrothed to Margaret, daughter of Frederick II.; and Pleissenland, a district west of Meissen, was added to his possessions. Having gained Thuringia and the Saxony palatinate on his uncle's death in 1247, he granted sections of his lands to his three sons in 1265, but retained Meissen. A series of family feuds followed. His second son Dietrich died in 1285, and on Henry's own death in 1288 Meissen was divided between his two remaining sons, Albert (called the Degenerate) and Frederick, and his grandson Frederick Tutta, the son of Dietrich. Albert was engaged in struggles with his three sons, who took him prisoner in 1288; but he was released the following year by order of the German king Rudolph I. About this time he sold his portion of Meissen to his nephew Frederick Tutta, who held the title...
of margrave and ruled the greater part of the mark until his death in 1297. Albert's two remaining sons, Frederick and Dietrich or Diezmann, then claimed Meissen; but it was seized by King Adolph of Nassau as a vacant fief of the empire, and was for some time retained by him and his successor King Albert I. In the course of constant efforts to secure the mark the brothers Frederick and Dietrich defeated the troops of King Albert at Lucka in May 1307 and secured partial possession of their lands. In this year Dietrich died and Frederick became reconciled with his father, who, after renouncing his claim on Meissen for a yearly payment, died in 1314. Having obtained possession of the greater part of the mark, Frederick was invested with it by the German king Henry VII. in 1310. During these years the part of Meissen around Dresden had been in the possession of Frederick, youngest son of the margrave Henry the Illustrious, and when he died in 1316 it came to his nephew Frederick. About 1312 Frederick, who had become involved in a dispute with Waldemar, margrave of Brandenburg, over the possession of lower Lusatia, was taken prisoner. Surrendering lower Lusatia he was released, but it was only after Waldemar's death in 1319 that he obtained undisputed possession of Meissen. Frederick, who was surnamed the Peaceful, died in 1323 and was followed as margrave by his son Frederick II., called the Grave, who added several counties to his inheritance. From this latter Frederick's death in 1349 until 1381 the lands of the family were ruled by his three sons jointly; but after the death of his eldest son Frederick III. in 1361 a division was made by which Meissen fell to his youngest son William I. In 1407 William was succeeded by his nephew Frederick, called the Warlike, who in 1423 received from the emperor Sigismund the electoral duchy of Sax-Wittenberg. The mark then became merged in the duchy of Saxony, and at the partition of 1485 fell to the Albertine line. As Meissen was relieved from the attacks of the Slavs by the movement of the German boundary to the east, its prosperity increased. Many towns were founded, among which were Dresden, Leipzig and Freiburg; Chemnitz began its textile industry; and although the condition of the peasants was wretched, that of the towns had improved. The discoveries of silver brought great wealth to the margraves, but they resorted at times to beds, which were contributions from the nobles and ecclesiastics who met in a kind of diet. During this period the mark of Meissen lay on both banks of the Elbe, and stretched from Bohemia to the duchy of Sax-Wittenberg, embracing an area of about 3000 sq. m.

MEISSONIER, J. L. E.

of the influence of Chenavard, to the class of work he was born to excel in, and exhibited with much success the "Game of Chess" (1841), the "Young Man playing the Cello" (1842), "The Painter in his Studio" (1843), "The Guard Room," the "Young Man looking at Drawings," the "Game of Piquet" (1845), and the "Game of Bowls"—works which show the finish and certainty of his technique, and assured his success. After his "Soldiers" (1848) he began "A Day in June," which was never finished, and exhibited "A Smoker" (1849) and "Bravos" ("Les Braví", 1852). In 1855 he touched the highest mark of his achievement with "The Gamblers" and "The Quarrel" ("La Rixe"), which was presented by Napoleon III. to the English Court. His triumph was sustained at the Salon of 1857, when he exhibited nine pictures, and drawings; among them the Young Man of the Time of the Regency," "The Painter," "The Shoewing Smith," "The Musician," and "A Reading at Diderot's," To the Salon of 1861 he sent "The Emperor at Solferino," "A Shoewing Smith," "A Musician," "A Painter," and "M. Louis Fould"; to that of 1864 another version of "The Emperor at Solferino," and "1814." He subsequently exhibited "A Gamblers' Quarrel" (1862), and "Deiss and the Army of the Rhine" (1867). Meissonier worked with elaborate care and a scrupulous observation of nature. Some of his works, as for instance his "1807," remained ten years in course of execution. To the great Exhibition of 1878 he contributed sixteen pictures: the portrait of Alexandre Dumas which had been seen at the Salon of 1877, "Cuirassiers of 1805," "A Venetian Painter," "Moreau and his Staff before Höhlninden," a "Portrait of a Lady," the "Road to La Salïce," "The Two Friends," "The Outpost of the Grand Guard," "A Smoker," and "Dictating his Memoirs." Thenceforward he exhibited less in the Salons, and sent his work to smaller exhibitions. Being chosen president of the Great National Exhibition in 1883, he was represented there by such works as "The Pioneer," "The Army of the Rhine," "The Arrival of the Guests," and "Saint Mark." On the 24th of May 1884 an exhibition was opened at the Petit Gallery of Meissonier's collected works, including 146 examples. As president of the jury on painting at the Exhibition of 1889 he contributed some new pictures. In the following year the New Salon was formed (the National Society of Fine Arts, and Meissonier was president. He exhibited there in 1890 his picture "1807"; and in 1891, shortly after his death, his "Barricade was displayed there. A less well-known class of work than his painting is a series of etchings: "The Last Supper," "The Skill of Vailliane the Little Smoker," and the "Preparations for a Duel," "Anglers," "Troopers," "The Reporting Sergeant," and "Polichinelle," in the Hertford House collection. He also tried lithography, but the prints are now scarcely to be found. Of all the painters of the century, Meissonier was one of the most fortunate in the matter of payments. His "Cuirassiers," now in the late duc d'Aumale's collection at Chantilly, was bought from the artist for £1,000, sold at Brussels for £1,100, and finally resold for £1,600. Besides his genre portraits, he painted some others: those of "Doctor Lefevre," of "Chenavard," of "Vanderbilt," of "Doctor Guyon," and of "Stanford." He also collaborated with the painter Français in a picture of "The Park at St. Cloud." In 1838 Meissonier married the sister of M. Steinheil, a painter. Meissonier was attached by Napoleon III. to the imperial staff, and accompanied him during the campaign in Italy and at the beginning of the war in 1870. During the siege of Paris in 1871 he was colonel of a marching regiment. In 1840 he was awarded a third-class medal, a second-class medal in 1841, first-class medals in 1843 and 1844 and medals of honour at the great exhibitions. In 1846 he was appointed knight of the Legion of Honour and promoted to the higher grades in 1856, 1867 (June 29), and 1880 (July 12), receiving the Grand Cross in 1889 (Oct. 29). He nevertheless cherished certain ambitions which remained unfilled. He hoped to become a professor at the École des Beaux Arts, but the appointment he desired was never given to him. On various occasions,
too, he aspired to be chosen deputy or made senator, but he
was not elected. In 1861 he succeeded Abel de Pujol as member of
the Academy of Fine Arts. On the occasion of the centenary
festival in honour of Michelangelo in 1875 he was the delegate
of the Institute of France to Florence, and spoke as its represen-
tative. Meissonier was an admirable draughtsman upon wood,
his illustrations to Les Contes Rêmois (engraved by Lavoignat),
to Lamartine’s Fall of an Angel, to Paul and Virginia, and to
The French Painted by Themselves being among the best known.
The leading engravers and etchers of France have been engaged
upon plates from the works of Meissonier, and many of these
plates command the highest esteem of collectors. Meissonier
died in Paris on the 21st of January 1891. His son, Jean
Charles Meissonier, also a painter, was his father’s pupil, and
was admitted to the Legion of Honour in 1889.

Meissonier (London, 1882). (H. F.)

MEISSONIER, JUSTE AURÈLE (1695-1750), French gold-
smith, sculptor, painter, architect, and furniture designer,
was born at Courtray, and became an artist of Pari, where
he died. His Italian origin and training were probably
responsible for the extravagance of his decorative style. He
shared, and perhaps distanced, the meritorious triumphs of
Oppenard and Germain, since he dealt with the Baroque
in its most daring and flamboyant developments. Rarely
does he leave a foot or two of undecorated space; the effect
of the whole is futile and fatiguing. It was because Meissonier
carried the style of his day to its extreme that he acquired
so vast a popularity. Like the English brothers Adam at a
later day he not only as architect built houses, but
as painter and decorator covered their internal walls; he
designed the furniture and the candlesticks, the silver and
the decanters for the table; he was as ready to produce a
snuff-box as a watch case or a sword hilt. Not only in
France, but for the nobility of Poland, Portugal and other
countries which took their fashions and their taste from Paris,
he made designs, which did nothing to improve European
taste. Yet his accomplishment was not wholly without merit.
His work in gold and silver plate was often graceful and some-
times bold and original. He was least successful in furniture,
where his twirls and convolutions, his floral and roccaille motives
were conspicuously offensive. He was appointed by Louis XV.
Dessinateur de la chambre et du cabinet de roi; the post of
designer pour les pompes funèbres et galantes was also held along
with that of Officier du roi.

For our knowledge of his work we are considerably indebted
to his own books of design: Livre d’ornements en trente pièces;
Livre d’orfèvrerie d’église en six pièces, and Ornaments de la carte
chronologique.

MEISTERSINGER (Ger. for “master-singer”), the name
given to the German lyric poets of the 14th, 15th and 16th
centuries, who carried on and developed the traditions of
the medieval Minnesingers (q.v.). These singers, who, for the most
part, belonged to the artisan and trading classes of the German
towns, regarded as their masters and the founders of their
gold twelve poets of the Middle High German period, among
whom were Wolfram von Eschenbach, Konrad von Würzburg,
Reinmar von Zweter and Frauenlob. The last mentioned
of these, Frauenlob, is said to have established the earliest
Meistersinger school at Mainz, early in the 14th century.
This is only a tradition, but the institution of such schools originated
undoubtedly in the upper Rhine district. In the 14th century
there were schools at Mainz, Strassburg, Frankfort, Würzburg,
Zürich and Prague; in the 15th at Augsburg and Nuremberg,
the last becoming in the following century, under Hans Sachs,
the most famous of all. By this time the Meistersinger schools
had spread all over south and central Germany; and isolated
gilds were to be found farther north, at Magdeburg, Breslau,
Görlitz and Danzig.

Each gild numbered various classes of members, ranging
from beginners, or Schüller (who were equivalent to Gesellen or journey-
men), to Meister, a Meister being a poet who was not merely
able to write new verses to existing melodies but had himself
invented a new melody. The poem was technically known as a
Bar or Geset, the melody as a Ton or Weis. The songs
were all sung in the schools without accompaniment. The
rules of the art were set down in the so-called Tabulatur or
law-book of the guild. The meetings took place either in the
Rathaus, or town hall, or, when they were held—as was usually
the case—on Sunday, in the church; and three times a year,
at Easter, Whit-Sunday and Christmas, special festivals and
singing competitions were instituted. At such competitions
or Schulungs judges were appointed, the so-called Merker,
whose duty it was to criticize the competitors and note their
offences against the rules of the Tabulatur.

The literary value of the Meistersinger poetry was hardly
in proportion to the target and the life of the German
towns in the 15th and 16th centuries. As the medieval lyric
decayed, more and more attention was given to the externals
of poetic composition, the form, the number of syllables, the
melody; and it was such externals that attracted the interest
of these burgher-poets. Poetry was to them a mechanical art
that could be learned by diligent application, and the prizes
they had to bestow were the rewards of ingenuity, not
of genius or inspiration. Consequently we find an extraordinary
development of strophic forms corresponding to the many new
“tones” which every Meistersinger regarded as his duty to
invent—tones which bore the most remarkable and often ridicu-
ulous names, such as Gestreiftefranbhumleiteweis, Fettadachsweis,
Vielfrassweis, gehämmte Paradiesweis, &c. The verses were
adapted to the musical strophes by a merely mechanical
counting of syllables, regardless of rhythm or sense. The
meaning, the sentiment, the thought, were the last things to
which the Meistersingers gave heed. At the same time there was
a certain healthy aspect in the cultivation of the Meistersanges
among the German middle classes of the 15th and 16th centuries;
the Meistersinger poetry, if not great or even real poetry, had
—especially in the hands of a poet like Hans Sachs—many
germs of promise for the future. It reflected without exaggera-
tion or literary veneer the faith of the German burgher, his
blunt good sense and honesty of purpose. In this respect it
was an important factor in the rise of that middle-class literature
which found its most virile expression in the period of the
Reformation. The Meistersenge reached its highest point in
the 16th century; and it can hardly be said to have outlived
that epoch, although the traditions of the Meistersingers lingered
in south German towns even as late as the 19th century.

Specimens of Meistersinger poetry will be found in various
collections, such as J. J. Görres, Altdutsche Volks- und Meisterlieder
(1817); K. Bartholomäus, Meistersinger der Kolmarer Handschrift (Publ.
of the Stuttgart Literarischer Verein, vol. ii.); 1862). Of the
older sources of information about the Meistersingers the most important
are Adam Fuchsheim, Gründlicher Bericht des deutschen Meister-
esanges (1805); Ulrich von Zassen, Neudrucke der deutschen Dichterwerke des
16. und 17. Jahrh., 73, 1888); and J. C. Wagensel, Der civitate norbergenis (1677). See further J. Grimm, Uber den altdeutschen Meistersang (1811); F. Schrorr,
Teutsches Zunftbuch (1823); A. Schmitz, Deutsche Forschung (1872); R. v. Lilienron, Uber den Inhalal der allgemeinen Bildung in der
Zeit der Scholastik (1876); G. Jacobsthal, Die musikalische Bildung der Meistersinger (Zeitschrift für deutsch. Altertum, xx. 1876); O. Lyon, Du Meister-und der Meistergesang (1883); K. Mey, Der Meistersang, Geschichte und Kunst (1899). The art of the Meistersingers has been immortalized by Richard Wagner in his music drama, Die Meister-
singer (1868). (J. G. R.)

MEKONG, or MÉNAM KONG (pronounced Kaung), sometimes
known as the Cambodia River, the great river of Indo-China,
having its origin in the Tibetan highlands. It is the third or
fourth longest river in Asia and the seventh or eighth in the
world. It is about 2600 m. in length, of which 1200 flow through
portions of the Chinese Empire and Tibet and 1600 through
French territory. Its sources are not definitely settled, but it
is supposed to rise on the slopes of Dea-Nag-Lung-Mung in about
MELA—MELAMPUS

87

33° N., 95° E., at an altitude of 16,700 ft. above sea-level. Throughout the greater part of its course in Tibet, where it is called the Dza-Chu, it flows south-eastwards to Chiamo, on the great east and west caravan route from China to Lhasa. At this point it is about 10,000 ft. above sea-level. From here it flows southwards through little-known mountain wastes. Below Dayul in lat. 20° it is known by the Chinese name of Lantsan Kiang. For the next 300 m. of its course the Lantsan Kiang, or, as it soon becomes known among the Thai peoples inhabiting its rugged valley, the Mekong, is very little known to us. The river flows beneath bare and rocky walls. A few scattered villages of Lusus and Mossos exist in this region; there is no trade from north to south. In 25° 28' N. the Tali-Bhamo caravan route, described by Colborne Baker, crosses the river by one of those iron suspension bridges which are a feature of Yun-nan, at a height of 4,700 ft. above sea-level. From this point to Chieng or Keng Hung, the head of the old confederacy of the Sibsawng Punna or Twelve States, it is little known; the fact that it falls some 900 ft. for each degree of latitude indicates the character of the river. Under the provisions of the Anglo-French agreement of January 1856, from the Chinese frontier southwards to the mouth of the Nam Hok the Mekong forms the frontier between the British Shan States on the west, and the territories acquired from Siam by France in 1863. By the treaty of 1863 from that point southwards to about 13° 30' N. it is also the frontier between French Indo-China and Siam, and a zone extended 25 kilometres inland from the right bank, within which the Siamese government agreed not to construct any fortified port or maintain any armed force. This 25 kilometre neutral zone was abolished in 1905 when France surrendered Chantabun to the Siamese, who in their turn ceded the port of Krat and the provinces of Melbuquerque and Bassac, together with various trading concessions to France on the right bank of the Mekong. Below the Siamese town of Chiang Sen the river takes its first great easterly bend to Luang Prabang, being joined by some important tributaries. This portion is obstructed by rapids. The country is mountainous, and the vegetation of the lower heights begins to assume a tropical aspect. From Luang Prabang the river cuts its way southwards for two degrees through a lonely jungle country among receding hills of low elevation. From Chieng Khan the river again turns eastwards along the 18th parallel, forcing its way through its most serious rapid-barrier, and receiving some important tributaries from the highlands of Tung Chieng Kum and Chieng Kwang, the finest country in Indo-China. In 104° E. the river resumes a southerly course through a country thinly peopled. At Kemarat (16° N.) the fourth serious rapid-barrier occurs, some 60 m. in length, and the last at Khong in 14° N. From here to its outfall in the China Sea the river winds for some 400 m. through the French territories of Cambodia and Cochín China, and to its annual overflow these countries owe their extraordinary fertility. The French have done much to render the river navigable. Steamers ply regularly from Saigon through Mytho to Phnom Penh, and launches proceed from this place, through the difficult river, to the Cambodian rapids, and beyond this a considerable portion of the distance to Luang Prabang, the journey being finished in native boats.

MELA, POMPONIUS (fl. c. A.D. 43), the earliest Roman geographer. His little work (De situ orbis libri III.) is a mere compendium, occupying less than one hundred pages of ordinary print, dry in style and deficient in method, but of pure Latinity, and occasionally relieved by pleasing word-pictures. Excepting the geographical parts of Pliny’s Historia naturalis (where Mela is cited as an important authority) the De situ orbis is the only formal treatise on the subject in classical Latin. Nothing is known of the author except his name and birthplace—the small town of Tingenata or Cingentara in southern Spain, on Algeciras Bay (Mela li. 6, § 96; but the text is here corrupt). The date of his writing may be approximately fixed by his allusion (iii. 6 § 49) to a proposed British expedition of the reigning emperor, almost certainly that of Claudius in A.D. 43. That this passage cannot refer to Julius Caesar is proved by several references to events of Augustus’s reign, especially to certain new names given to Spanish towns. Mela has been without probability identified by some with L. Annius Mela of Corduba, son of Seneca the rhetorician, and brother of the great Seneca.

The general views of the De situ orbis mainly agree with those current among Greek writers from Eratosthenes to Strabo; the latter was probably unknown to Mela. But Pomponius is unique among ancient geographers in that, after dividing the earth into two hemispheres of which that of the north is inhabited by antichthones, inhabiting the southern temperate zone inaccessible to the folk of the northern temperate regions from the unbearable heat of the intervening torrid belt. On the divisions and boundaries of Asia, Europe, and Africa, he follows modern geographers like all earlier Greek writers; he follows Eratosthenes in supposing that country to occupy the south-eastern angle of Asia, whence the coast trends northwards to Scythia, and then swept round westward to the western extremity of Europe. He differs from Ptolemy. On the other hand, Mela was the first to name the Caspian Sea as an inlet of the Northern Ocean, corresponding to the Persian and Arabian (Red Sea) gulfs on the south. His Indian concepts were inferior to those of earlier Greek writers; he follows Eratosthenes in supposing that country to occupy the south-eastern angle of Asia, whence the coast trends northwards to Scythia, and then swept round westward to the western extremity of Europe. He differs from Ptolemy. In the west, his knowledge of Europe is much inferior to that of the earlier geographers. He defines the Mediterranean Sea by the mouth of the Bassac, the Bay of Biscay more accurately than Eratosthenes or Strabo, his ideas of the British Isles and their position are also clearer than his predecessors’. He is the first to name the Oreads and Orkneys, Sweden and Norway, and defines and locates pretty correctly. His knowledge of Africa is far inferior to that of Strabo, a point at which bay (“Cadanus sinus”) he does not. From Africa he names the countries adorning the south coast of the Mediterranean; then he names the rivers by Syria and Asia Minor to the Black Sea, and so returns to Spain along the north shore of the Euxine, Propontis, &c. After treating the Mediterranean islands, he next takes the ocean littoral—to west, north, east and south successively—from Spain and Gaul round to India, from India to Persia, Arabia and Ethiopia; and so returns to Europe. The most ancient of the classical geographers he conceives the Dark Continent as surrounded by sea and not extending very far south.

The first edition of Mela was published at Milan in 1471; the first English translation was made by Medius (Basil, 1632), superseded by those of Voss (1668), J. Gronovius (1655 and 1696), A. Gronovius (1722 and 1728), and Tschucke (1806–1807), in seven parts (Leipzig; the most elaborate of all); G. Patheisy’s (Berlin, 1807), gives the best text. On Mela see also E. H. Bunbury, Ancient Geography, ii. 352–369, and D. Detlefsen, Quellen und Forschungen zur älten Gesch. und Geog. (1908).

MELACONITE, a mineral consisting of cupric oxide, CuO, and known also as black copper ore. In appearance it is strikingly different from cuprite (c.v.t.) or red copper ore, which is cupric oxide. Crystals are rare; they belong to the monoclinic, or possibly to the anorhtic system, and have the form of thin triangular or hexagonal scales with a steel-grey colour and brilliant metallic lustre. More often the mineral is massive, earthy or pulverulent, and has a dull iron-black colour. Hence the name melacynite, from the Greek μέλας, black and κότυλος, that, which was originally given by P. S. Beudant in 1832 in the Bulletin des Sciences, in the constellation of the cryolite. This cryolite is now known as cryolite. The mineral was later named tenorite, a name commonly adopted for the species. The hardness of the crystals is 3–4, but the earthy and powdery forms readily soil the fingers; the spec. grav. is 5–9. Crystals have been found only at Mt. Vesuvius, where they encrust lava, and in Cornwall. The other forms of the mineral, however, are common in copper mines, and have resulted by the alteration of chalcolite, chalcopyrite and other copper ores, on which they often form a superficial coating.

(L. J. S.)

MELAMPUS, in Greek legend, a celebrated seer and physician, son of Amyth and Eidomone, brother of Bias, mythical eponymous hero of the family of the Melampodidae. Two young serpents, whose life he had saved, licked his ears while he slept, and from that time he understood the language of birds and beasts. In the art of divination he received instruction from Apollo himself. To gain the consent of Neleus, king of Pylos, to the marriage of his daughter Pero with Bias, Mela...
undertook to obtain possession of the oxen of the Thessalian prince Iphiclus. As Melampus had foretold, he was caught and imprisoned, but was released by Phylacus (the father of Iphiclus) on giving proof of his powers of divination, and was finally presented with the oxen as a reward for having rescued the virility of the son. Melampus subsequently obtained a share in the kingdom of Argos in return for having cured the daughters of its king Proetus, who had been driven mad for offering resistance to the worship of Dionysus or for stealing the gold from the statue of Hera. At Aegosthena in Megara there was a sanctuary of Melampus, and an annual festival was held in his honour. According to Herodotus, he introduced the character of Dionysus into Greece from Egypt, and his name ("black foot") is probably a "symbolical expression of his character as a Bacchic propitiatory priest and see" (Preliter). According to the traditional explanation, he was so called from his foot having been tanned by exposure to the sun when a boy. In his character of physician, he was the reputed discoverer of the herb melampodium, a kind of hellebore. Melampus and Bias are symbolic representatives of curing and force.

See Apollodorus i. 9, 11; ii. 32; iii. 2; Odyssey, xv. 225-240; Dio. Suid. iv. 68; Herodotus ii. 49; iv. 34; Pausanias ii. 18, 4; iv. 36, 3; scholiast on Theocritus iii. 43; Ovid, Metam. xv. 325; C. Eckermann, Melampus und sein Geschicht (1840).

Melampus is sometimes described as an author of short extant treatise of little value on Divination by means of Palpitation (Hsia lions) and Birthmarks (Ektaw). It probably dates from the time of Ptolemy Philadelphus (3rd cent. B.C.). Edition by J. G. Franz inScriptores physiognomiae veteres (1796).

**MELANCHLAENI** (from Gr. μελαν, and χαλκα, "Blackcloaks"), an ancient tribe to the north of Scythia, probably about the modern Ryazan and the Volga (Herodotus iv. 106). They have been identified with the Finnish tribes Merja (now extinct) and Cheremis, were drawn north-east on to the middle Volga. These, till recently, were white. There has been confusion between this tribe and another of the same name mentioned by Pliny (N. H. vi. 13), and Ptolemy in the Caucasus.

**MELANCHOLY** (Gr. μελανχολία, from μέλας, black, and χολή, bile), originally a condition of the mind or body due to a supposed excess of black bile, also this black bile itself, one of the chief "humours" of the body, which, according to medieval physiology, blood, phlegm, choler and melancholy (see HUMOUR); now a vague term for desponding grief. From the 17th century the name was used of the mental disease now known as "melancholia" (see INSANITY), but without any reference to the supposed cause of it.

**MELANCHTHON, PHILIPP** (1497-1560), German theologian and reformer, was born at Bretten in Baden on the 16th of February 1497. His father, George Schwartz, was an armourer under the Palatinate princes. His mother, Barbara Reuter, a niece of Johann Reuchlin, was shrewd, thrifty and affectionate. Her father, Johann Reuter, long burgomaster of Bretten, supervised the education of Philipp, who was taught first by Johannes Hungarus and then by Georg Simler at the academy of Pfortzheim. Reuchlin took an interest in him, and, following a contemporary custom, named him Melanchthon (the Greek form of Schwartz, black, earth). In October 1509 he went to Heidelberg, where he took the B.A. degree, afterwards proceeding M.A. at Tübingen. The only other academic distinction he accepted was the B.D. of Wittenberg (1519). He would never consent to become a "doctor," because he thought the title carried with it responsibilities to which he felt himself unequal. At Tübingen he lived as student and teacher for six years. Still on Reuchlin's advice, the elector of Saxony called him to Wittenberg as professor of Greek in 1518.

This appointment marked an epoch in German university education; Wittenberg became the school of the nation; the scholastic methods of instruction were set aside, and in a Discourse on Reforming the Studies of Youth Melanchthon gave proof not only that he had caught the Renaissance spirit, but that he was fitted to become one of its foremost leaders. He began to lecture on Homer and the Epistle to Titus, and in connection with the former he announced that, like Solomon, he sought Tyrian brass and gems for the adornment of God's Temple. Luther received a fresh impulse towards the study of Greek, and his translation of the Scriptures, begun as early as 1517, now made rapid progress, Melanchthon helping to collate the Greek versions and revising Luther's translation. Melanchthon felt the spell of Luther's personality and spiritual depth, and seems to have been prepared on his first arrival at Wittenberg to accept the new theology, which as yet existed mainly in subjective form in the person of Luther. To reduce it to an objective system, to exhibit it dialectically, the calmer mind of Melanchthon was requisite.

Melanchthon was first drawn into the arena of the Reformation controversy through the Leipzig Disputation (June 27-July 8, 1516), at which he was present. He had been reproved by Johann Eck for giving aid to Carlstadt ("Fac te, Philippe, ac tua studia curius regis," i.e., he was shortly afterwards attacked by the great professor). Melanchthon replied in a brief and moderately worded treatise, setting forth Luther's first principle of the supreme authority of Scripture in opposition to the patristic writings on which Eck relied. His marriage in 1520 to Catharina Krapp of Wittenberg gave a domestic centre to the Reformation. In 1521, during Luther's confinement in the Wartburg, Melanchthon was leader of the Reformation cause at the university. He defended the action of Carlstadt, when he dispensed the Eucharist in an "evangelical fashion." 1

With the arrival of the Anabaptist enthusiasts of Zwickau, he had a more difficult task, and appears to have been irresolute. Their attacks on infant baptism seemed to him not altogether irrational, and in regard to their claim to personal inspiration he said "Luther alone can decide; on the one hand let us beware of quenching the Spirit of God, and on the other of being led astray by the spirit of Satan." In the same year, 1521, he published his Locis communis rerum theologica-Commentarii, the first systematic presentation of the reformed theology. From 1522 to 1524 he was busy with the translation of the Bible and in publishing commentaries. In 1524 he went for reasons of health into southern Germany and was urged by the papal legate Campegio to renounce the new doctrines. He refused, and maintained his refusal by publishing his Summa doctrinarum Lutheri.

After the first Diet of Spires (1526), where a precarious peace was patched up for the reformed faith, Melanchthon was deputed as one of twenty-eight commissioners to visit the reformed states and regulate the constitution of churches, he having just published a famous treatise called the Libellus visitatorius, a "handbook" for the use of the commissioners. At the Marburg conference (1529) between the German and Swiss reformers, Luther was pitted against Oecolampadius and Melanchthon against Zwingli in the discussion regarding the real presence in the sacrament. How far the normally conciliatory spirit of Melanchthon was here biased by Luther's intolerance is evident from the exaggerated accounts of the conference written by the forger to the elector of Saxony. He was at this time even more embittered than Luther against the Zwinglians. At the Diet of Augsburg (1530) Melanchthon was the leading representative of the reformation, and it was he who prepared for that diet the seventeen articles of the Evangelical faith, which are known as the "Augsburg Confession." He held conferences with Roman divines appointed to adjust differences, and afterwards wrote an Apology for the Augsburg Confession. After the Augsburg

1 He read the usual service, but omitted everything that taught a propitiatory sacrifice; he did not elevate the Host, and he gave both the bread and the cup into the hands of every communicant.
conference further attempts were made to settle the Reformation controversy by a compromise, and Melanchthon, from his conciliatory spirit and facility of access, appeared to the defenders of the old faith the fittest of the reformers to deal with. His historical instinct led him ever to revert to the original unity of the church, and to regard subsequent errors as excrences rather than proofs of an essentially anti-Christian system. He was weary of the rabies theologorum, and dreamed that the evangelical leaven, if tolerated, would purify the church's life and doctrine. In 1537, when the Protestant divines signed the Lutheran Articles of Schmalkalden, Melanchthon appended to his signature the reservation that he would admit of a pope provided he allowed the gospel and did not claim to rule by divine right.

The year after Luther's death, when the battle of Mühlberg (1547) had given a seemingly crushing blow to the Protestant cause, an attempt was made to weld together the evangelical and the papal doctrines, which resulted in the compilation by Pflug, Sidonius and Agricola of the Augsburg "Interim." This was proposed to the two parties in Germany as a provisional ground of agreement till the decision of the Council of Trent. Melanchthon, on being referred to, declared that, though the Interim was inadmissible, yet so far as matters of indifference (adipora) were concerned it might be received. Hence arose that "adiaphoristic" controversy in connexion with which he has been misrepresented as holding among matters of indifference such cardinal doctrines as justification by faith, the number of the sacraments, as well as the dominion of the pope, feast-days, and so on. The fact is that Melanchthon sought, not to minimize differences, but to veil them with an intentional obscurity of expression, which allowed the necessity of good works to salvation, but not in the old sense; proposed to allow the seven sacraments, but only as rites which had no inherent efficacy to salvation, and so on. He afterwards recoiled with the adiaphora, and never really swerved from the views set forth in the "Loci communes;" but he regarded the surrender of more for less perfect forms of truth or of expression as a painful sacrifice rendered to the weakness of erring brethren. Luther, though he had probably uttered in private certain expressions of dissatisfaction with Melanchthon, maintained unbroken friendship with him; but after Luther's death certain smaller men formed a party emphasizing the extremest points of his doctrine.1 Hence the later years of Melanchthon were occupied with controversies within the Evangelical church, and in the main brought to a close by the Augsburg Interim and the Schmalkalden Articles, of which he had laid the foundations.

1 It must be admitted, however, that Matthias Flacius issued the Reformation.

189

Different method of treating grace which is possible to believers as to others. Man may pray for help and reject grace. This he calls free will, as the power of laying hold of grace. Melanchthon's two arguments of the three concurrent causes, of which the creature is, the Holy Spirit, the word and human will, suggested the semi-Pelagian position called Synergism, which was held by some of his immediate followers.

In regard to the relation of grace to repentance and good works, Luther was disposed to make faith itself the principle of sanctification. Melanchthon, however, for whom ethics possessed a special interest, laid more stress on the law. He began to do this in 1527 in the Libellus visitatorius, which urges pastors to instruct their hearers in the necessity and means of repentance of the laws of the Old Testament and of reducing the number of the laws to bear upon men in order to faith. This brought down upon him the opposition of the Antinomian Johannes Agricola. In the Loci of 1535 Melanchthon sought to put the fact of the new justification of the individual at the basis of a sure basis by declaring the latter necessary to eternal life, though the believer's destiny thereto is already fully guaranteed in his justification. In the Loci of 1543 he did not retain the doctrine of the necessity of good works in order to salvation, and to this he added, in the Leipzig Interim, "that this in no way connotes the error that eternal life is merited by the worthiness of our own works." Melanchthon was led to lay more stress upon the law and moral ideas; but the basis of the relation of faith and good works was never clearly brought out by him, and he at length fell back on his original position, that we have justification and inheritance of bliss in and by Christ alone, and that good works are disposable by reason of the grace of God of which they are the fruits.

BIBLIOGRAPHY.—The principal works of Melanchthon, with the bulk of his correspondence, are contained in the Corpus reformatorum scriptorum et historicorum hactenus; Halle, 1564–1600; and in Eberhard and Bindseil, to which was added Bindseil's Supplementum (Halle, 1874). Melanchthon's earliest and best biographer was his friend Joachim Camerarius (1566), a new annotated edition of which is now needful. The best modern life is that by Georg Ellis (Berlin, 1902); note also Schmidt's Forschungen (Leipzig, 1891). The celebration in 1897 of the 400th anniversary of Melanchthon's birth produced many short biographies and Festreden, among them one by J. W. R. Schmidt (New York and London, 1898); and by George Wilson (London, 1897); Karl Sell (Halle, 1897); Ferdinand Cohrs (Halle, 1897); Bessenhag and Harnack (1897). Richard Rothe's Festrede (1860) is also good. The most learned of modern scholars is Alben, who wrote Philipp Melanchthon als Preceptor Germaniae (Berlin, 1889), Melantchthoniana paedagogica (Leipzig, 1892), giving in the first named two full bibliographies, one of all works written on Melanchthon, the other of all works written by him (in chronological order). Hartfelder believed that a good deal of unpublished material is still left in German and foreign libraries. Thus three long unknown letters are published in the Quellen und Forschungen of the König. Preuss. Inst. Hist. at Rome, vol. ii. Two are to the Cardinal of Augsburg and one to Lazarus von Schwendi. Melanchthon was on his way to the Council of Trent as delegate of the elector of Saxony and the cardinal had offered to meet him at Dillingen. He arrived at Dillingen and met Dillingen without any prearrangement, which was not a national synod, which would have been a better means of arriving at the truth.

MELANESIA, one of the three great divisions of the oceanic islands in the central and western Pacific. It embraces the Bismarck Archipelago, N.E. of New Guinea, the Louisiade, Solomon, Santa Cruz, New Hebrides and Loyalty islands, New Caledonia, Fiji and intervening small groups. The name (Gr. melas, black, and vicinis, island) is derived from the black colour of the prevailing native race, the Papuans and its allied tribes. Many of these differ widely from the parent race, but all the Melanesians have certain characteristics which distinguish them sharply from the inhabitants of Polynesia and Micronesia. Their civilization is lower. The Melanesians are mostly "negroid," nearly black, with crisp, curly hair elaborately dressed; their women hold a much lower position among the Polynesians; their institutions, social, political and religious, are simpler, their manners rude; they have few or no traditions; cannibalism, in different degrees, is almost universal; but their artistic skill and taste, as with some of the lower African negroes, are remarkable, and they are amenable to discipline and fair treatment. Their languages, which exhibit considerable difference among themselves, have features which mark them off clearly from the Polynesian, notwithstanding certain fundamental relations with the latter.

See R. H. Codrington, The Melanesian Languages (Oxford, 1885) and The Melanesians (Oxford, 1891); the articles PAPUANS and PACIFIC OCEAN; also those on the several island-groups, &c.
MELANTHIUS—

**MELANTHIUS**, a noted Greek painter of the 4th century B.C. He belonged to the school of Sicyon, which was noted for fine drawing.

**MELBOURNE,** the capital of Victoria, and the most populous city in Australia. It is situated on Hobson’s Bay, a northern bend of the great harbour of Port Phillip, in Bourke county, about 500 m. S.W. of Sydney. The suburbs extend along the shores of the bay for more than 10 m., but the part distinctively known as the “city” occupies a site about 3 m. inland on the north bank of the Yarra river. The appearance of Melbourne from the sea is by no means picturesque. The busy shipping suburbs of Port Melbourne and Williamstown occupy the flat alluvial land at the mouth of the Yarra. But the city itself has a different aspect; its situation is relieved by numerous gentle hills, which show up its fine public buildings to great advantage; its main streets are wide and well kept, and it has an air of prosperity, activity and comfort. The part especially known as the “city” occupies two hills, and along the valley between them runs the thoroughfare of Elizabeth Street. Parallel to this is Swanston Street, and at right angles to these, parallel to the river, are Bourke Street, Collins Street and Flinders Street—the first being the busiest in Melbourne, the second the most fashionable with the best shops, and the third, which faces the river, given up to the maritime trade. These streets are an eighth of a mile apart, and between each is a narrower street bearing the name of the wider, with the prefix “Little.” The original plan seems to have been to construct these narrow streets to give access to the great business houses which, it was foreseen, would be built on the frontage of the main streets. This plan, however, miscarried, for space grew so valuable that large warehouses and business establishments have been erected in these lanes. Little Flinders Street, in which the great importers’ warehouses are mainly situated, is locally known as “the Lane.” In the centre of the city some of the office buildings are ten, twelve or even fourteen storeys high. The main streets are 90 ft. wide, and the lanes somewhat less than half that width. Round the city lies a circle of populous suburbs—to the north-east Fitzroy (pop. 31,687) and Collingwood (32,749), to the east Richmond (37,824), to the south-east Prahran (40,441), to the south South Melbourne (40,619), to the south-west Port Melbourne (12,176), and to the north-west North Melbourne (18,120). All these suburbs lie within 3 m. of the general post office in Elizabeth Street; but outside them and within the 5 m. radius is another circle—the east Kew (9469) and Hawthorne (21,430), to the south-east St Kilda (20,542) and Brighton (10,047), to the south-west Williamstown (14,052) and Footscray (18,318), to the north-west Essendon (17,426), and Flemington and Kensington (19,949), and to the north Brunswick (24,141). Numerous small suburbs fill the space between the two circles, the chief being Northcote, Preston, Camberwell, Toorak, Caulfield, Elsternwick and Coburg. Some of these suburbs are independent cities, others separate municipalities. In spite of the value of land, Melbourne is not a crowded city.

The Parliament House, standing on the crown of the eastern hill, is a massive square brick building with a pillared freestone façade approached by a broad flight of steps. The interior is lavishly decorated and contains, besides the legislative chamber, a magnificent library of over 53,000 volumes. At the top of

MELCHERS—MELEAGER

MELCHERS, (JULIUS) GARI (1860— ), American artist, was born at Detroit, Michigan, on the 11th of August 1860. The son of a sculptor, at seventeen he was sent to Düsseldorf to study art under von Gebhardt, and after three years went to Paris, where he worked at the Académie Julien and the École des Beaux Arts. Attracted by the pictorial side of Holland, he settled at Egmond. His first important Dutch picture, "The Sermon," brought him honourable mention at the Paris Salon of 1886. He became a member of the National Academy of Design, New York; the Royal Academy of Berlin; Société Nationale des Beaux Arts, Paris; International Society of Painters, Sculptors and Engravers, London, and the Secession Society, Munich; and, besides receiving a number of medals, his decorations include the Legion of Honour, France; the order of the Red Eagle, Germany; and knight of the Order of St Michael, Bavaria. Besides portraits, his chief works are: "The Supper at Emmaus," in the Krupp collection at Essen; "The Family," National Gallery, Berlin; "Mother and Child," Luxembourg; and the decoration, at the Congressional Library, Washington, "Peace and War."

MELCHIADES, or MELIADAS (other forms of the name being Meltiades, Melciades, Miliades and Miltides), poet from the 2nd of July 310, to the 11th January 314. He appears to have been an African by birth, but of his personal history nothing is known. The toleration edicts of Galerius and of Constantine and Licinius were published during his pontificate, which was also marked by the holding of the Lateran synod in Rome (313) at which Caecilianus, bishop of Carthage, was acquitted of the charges brought against him and Donatus condemned. Melchiades was preceded and followed by Eusebius and Silvester I. respectively.

MELCHITES (lit. Royalists, from Syriac melcha, a king), the name given in the 5th century to those Christians who adhered to the creed supported by the authority of the Byzantine emperor. The Melchites therefore are those who accept the decrees of Ephesus and Chalcedon as distinguished from the Nestorians and Jacobite Church (q.v.). They follow the Orthodox Eastern liturgy, ceremonial and calendar, but acknowledge the papal and doctrinal authority of Rome. They number about 80,000, are found in Syria, Palestine and Egypt, and are under the immediate rule of the patriarch of Damascus and twelve bishops.

MELCHIZEDEK (Heb. for "king of righteousness"; or, since Šedek is probably the name of a god, "Šedek is my king"), king of Salem and priest of "supreme El" (El 'elyon), in the Bible. He brought forth bread and wine to Abraham on his return from the expedition against Chedorlaomer, and blessed him in the name of the supreme God, possessor (or maker) of heaven and earth; and Abraham gave him tithes of all his booty (Gen. xiv. 18–20). Biblical tradition tells us nothing more about Melchizedek (cf. Heb. vii. 3); but the majestic figure of the king-priest, prior to the priesthood of the law, to whom even the father of all Israel paid tithes (cf. Jacob at Bethel, Gen. xxviii. 20), is suggested a figurative or typical application, first in Psalm cx. to the viceregent of Yahweh, seated on the throne of Zion, the king of Israel who is also priest after the order of Melchizedek, and then, after the Gospel had ensured the Messianic interpretation of the Psalm (Matt. xxi. 42 seq.), to the kingly priesthood of Jesus, as that idea is worked out at length in the Epistle to the Hebrews.

The theological interest which attaches to the idea of the pre-Aaronic king-priest in these typical applications is practically independent of the historical questions suggested by the narrative of Melchizedek. Though connected with the main narrative by the epistles given to Yahweh in Gen. xiv. 22, breaks the natural connexion of verses 17 and 21, and may perhaps have come originally from a separate source, as the narrative now stands, it is be sought in the vicinity of "the king's dale," which from 2 Sam. xviii. 18, probably, but not necessarily, lay near Jerusalem. That Salem is Jerusalem, as in Psalm lxvi. 2.

is the ancient and common view; but even in the 15th century B.C. Jerusalem was known as Uru-salim. Jerome and others have identified Salim with one of the various places which bear that name, e.g. the 2αλαια of John iii. 23, 8 m. south of Beth-šemesh. In a genuine record of extant antiquity the union of king and priest in one person, the worship of El as the supreme deity by a Canaanite, and the widespread practice of the consecration of a tithe of booby can present no difficulty; but, if the historical sense of the narrative is denied, the date of the conception must be placed as late as the rise of the temporal authority of the high priests after the exile. So far no evidence has been found in the cuneiform inscriptions or elsewhere in support either of the figure or the name, and the union of the two offices into one is of the antiquity which is attributed to it (see further, J. Skinner, Genesis, p. 290 seq.). An ancient legend identifies Melchizedek with Sem (Palestinian Targum, Jerome on Isa. xlii., Ephebra Syrus in loco).

See further the literature on Gen. xiv., and on the names ABRAHAM, GENESIS. (W. R. S.; S. A. C.)

MELOCMBE, GEORGE BUBB DODDINGTON, BARON (1601–1762), English politician. His father's name was Bubb, but the son took the name of Doddington on inheriting a large property by the death of an uncle of that name (1720). He was educated at Oxford. In 1715 he was returned to parliament as member for Winchelsea, and was sent as envoy extraordinary to Spain. He carried on a scandalous traffic in the five or six parliamentary votes which he controlled, his turgiversion and venality furnishing food for the political satirists and caricaturists of the day. His most estimable political action was his defence of Admiral Byng in the House of Commons (1757). From 1722 to 1754 he sat in parliament for Bridgewater; from 1724 to 1740 was a lord of the treasury; and, in 1744, became treasurer of the navy under Henry Pelham, and, again in 1755, under Newcastle and Fox. In April 1761 he was raised to the peerage as Baron Melcombe of Melcombe Regis in Dorsetshire. He died at La Trappe, his Hammersmith house, on the 28th of July 1762. His wife, acknowledged only after the death of another lady to whom he had given a bond that he would marry no one else, died without issue. He was a wit and a friend of wits, a good scholar, and something of a Maccenas; Thomson's "Summer" was dedicated to him, Fielding addressed to him an epistle and Edward Young a satire. He was a leading spirit of the "Hell-fire" Club, whose members, called "Francescans," from their founder Sir Francis Dashwood (d. 1781), held their revels in the ruined Cistercian abbey of Medmenham, Bucks.

His diary, published in 1784, reveals him in his character of place-hunter and throws a curious light on the political methods of the time.

MELEAGER (Gk. Μελέγαιρος), in Greek legend, the son of Oeneus, king of Calydon, and Althaea. His father having neglected to sacrifice to Artemis, she sent a wild boar to ravage the land, which was eventually slain by Meleager. A war broke out between the Calydonians and Curetes (led by Althaea's brothers) about the disposal of the head and skin, which Meleager awarded as a prize to Atalanta, who had inflicted the first wound; the brothers of Althaea lay in wait for Atalanta and robbed her of the spoils, but were slain by Meleager. When Althaea heard this, she cursed Meleager, who withdrew, and refused to fight until the Curetes were on the point of capturing the city of Calydon. Then, yielding to his wife's entreaties, he sallied forth and defeated the enemy, but was never seen again, having been carried off by the Erinyes, who had heard his mother's curse (or he was slain by Apollo in battle). According to a later tradition, not known to Homer, the Moerae appeared to Althaea when Meleager was seven days old, and announced that the child would only live as long as the log blazing on the hearth of Althaea's house. Meleager thereupon seized the log, extinguished the flames and he lived. But after her brothers' death, she relighted the log, and let it burn away until Meleager died. Then, horrified at what she had done, she hanged herself, or died of grief. The sisters of Meleager were

1 It is to be noted also that the name is of the same form as Adoni-zedek, king of Jerusalem (Josh. x. 1), and that the un-Hebraic Araunah of 2 Sam. xxiv. 16 is probably a corruption of the similar compound Adonjah (so Cheyne, Encyc. Bib. col. 290).

2 The god Ἐναυρως was also Phoenician; see Driver, Genesis, p. 165; Lagrange, Religions Sémitiques, Index, s.v.

MELEDA—MELETIUS OF ANTIOCH

changed by Artemis out of compassion into guinea fowls and removed to the island of Leros, where they mourned part of the year for their brother. The life and adventures of Meleager are the subject in ancient literature and art. Meleager is represented as a tall, vigorous youth with curly hair, holding a javelin or a boar's head, and accompanied by a dog.

See R. Kekulé, De fabula meleagri dissertatio (1861); Surber, Die Meleagresage (Zürich, 1880); articles on "Meleager" and "Meleagrides" in Roscher's Lexikon der Mythologie; L. Preller, Griechische Mythologie; Apollodorus i. 8; Homer, Iliad, ix. 577; Dio, in vita Ptolemaei. Di Ovid, Metam. v. 260-545. In the article GREEK ART (fig. 41) the hunting of the Calydonian boar is represented on a fragment of a frieze from a heroon.

MELEDA (Serbo-Croatian, Mljet; Lat. Melita), the most southerly and easterly of the larger Adriatic islands of the Austrian province of Dalmatia. Pop. (1890), 1017. Meleđa lies south of the Sabioncello promontory, from which it is divided by the Meleda Channel. Its length is 23 m.; its average breadth 2 m. It is of volcanic origin, with numerous chasms and gorges, of which the longest, the Babino polje, connects the north and south of the island. Port Palazzo, the principal harbour, on the north, is a port of call. The monastery was built on the island of the Melita on which St Paul was shipwrecked, this view being first expounded, in the 10th century, by Constantine Porphyrogenitus. As at Malta, a "St Paul's Bay" is still shown.

MELEGNA (formerly Marignana), a town of Lombardy, Italy, in the province of Milan, 11 m. S.E. of that city by the railway to Piacenza, 289 ft. above sea-level. Pop. (1890), 6782. There are remains of a castle of the Visconti. Its military importance is due to its position at the crossing of the river Lambrone. It was a stronghold of Milan in her great struggle against Lodi, and is famous for the victory of Francis I. of France over the Swiss in 1515, known as the battle of Morignan, and for the action between the French and Austrians in 1859.

MELENZ VALDES, JUAN (1754–1827), Spanish poet, was born at Ribera del Fresno, Badajoz, on the 11th of March 1754. Destined by his parents for the priesthood, he graduated in law at Salamanca, where he became inordinately fond of the ideas of the French philosophical school. In 1780 with Batió, a pastoral in the manner of Gárcilaso de la Vega, he was a prize offered by the Spanish academy; next year he was introduced to Jovellanos, through whose influence he was appointed to a professorship at Salamanca in 1783. The pastoral scenes in Las Bosas de Camacho (1784) do not compensate for its undramatic nature, but it gained a prize from the municipality of Madrid. A volume of verses, lyrical and pastoral, published in 1785, caused Melendez Valdés to be hailed as the first Spanish poet of his time. This success induced him to resign his chair at Salamanca, and try his fortune in politics. Once more the friendship of Jovellanos obtained for him in 1789 a judgeship at Saragossa, whence he was transferred two years later to a post in the chancery court at Valladolid. In 1797 he dedicated to Godoy an enlarged edition of his poems, the new matter consisting principally of unsuccessful imitations of Milton and Thomson; but the poem was rewarded by promotion to a high post in the army at Madrid. On the fall of Jovellanos in 1798 Melendez Valdés was dismissed and exiled from the capital: he returned in 1808 and accepted office under Joseph Bonaparte. He had previously denounced the French usurper in his verses. He now outraged the feelings of his countrymen by the grossest flattery of his foreign master, and in 1813 he fled to Alais. Four years later he died in poverty at Montpellier. His remains were removed to Spain in 1900. In natural talent and in acquired accomplishment Melendez Valdés was not surpassed by any contemporary Spaniard; he failed from want of character, and his profound insincerity affects his poems. Yet he has fine moments in various veins, and his imitation of Jean Second's Basia is notable.

MELETIUS OF ANTIOCH (d. 381). Catholic bishop and saint, was born at Melitene in Lesser Armenia of wealthy and noble parents. He first appears (c. 357) as a supporter of Acacius, bishop of Caesarea, the leader of that party in the episcopate which supported the Homoian formula by which the emperor Constantius sought to effect a compromise between the Homœans and the Arians. Meletius thus makes his début as an ecclesiastical court party, and as such became bishop of Sebaste in succession to Eustathius, deposed as an Homœan heretic by the synod of Melitene. The appointment was resisted by the Homœonian clergy, and Meletius retired to Beroea. According to Socrates he attended the synod of Seleucia in the autumn of 359, and then subscribed the Arian formula. Early in 366 he became bishop of Antioch, in succession to Eudoxius, who had been raised to the see of Constantinople. Early in the following year he was in exile. According to an old tradition, supported by evidence drawn from Epiphanius and Chrysostom, this was due to a sermon preached before the emperor Constantius, in which he revealed Homœan views. This explanation, however, is rejected by Loofs; the sermon contains nothing inconsistent with the Arian position, and the clergy, quite apart from any questions of orthodoxy, which may have led to the bishop's resignation.

The successor of Meletius was Eusebius, who had fallen with Arius under the ban of Athanasius; and Loofs explains the subita fede mutatio which St Jerome (ann. A.D. 376) ascribes to Meletius to the dogmatic opposition of the deposed bishop to his successor. In Antioch itself Meletius continued to have adherents, who held separate services in the "Apostolic" church in the old town. The Meletian schism was complicated, moreover, by the presence in the city of another anti-Arian sect, stricter adherents of the Homœan formula, maintaining the tradition of the deposed bishop Eustathius and governed at this time by the presbyter Paulinus. The synod of Alexandria sent deputies to attempt an arrangement between the two anti-Arian Churches; but before they arrived Paulinus had been consecrated bishop by Lucifer of Calaris, and when Meletius—free to return in consequence of the emperor Julian's contemptuous opinion of the "Roman bishops"—took the field himself one of three rival bishops, Meletius was now between two stools. The orthodox Nicene party, notably Athanasius himself, held communion with Paulinus only; twice, in 365 and 371 or 372, Meletius was exiled by decree of the Arian emperor Valens. A further complication was added when, in 375, Vitalius, one of Meletius's presbyters, was consecrated bishop by the heretical bishop Apollinaris of Laodicea.

Meanwhile, under the influence of his situation, Meletius had been more and more approximating to the views of the new school of Nicene orthodoxy. Basil of Caesarea, throwing over the cause of Eustathius, championed that of Meletius who, when after the death of Valens he returned in triumph to Antioch, was hailed as the leader of Eastern orthodoxy. As such he presided, in October 379, over the great synod of Antioch, in which the dogmatic agreement of East and West was established; it was he who helped Gregory of Nazianzus to the see of Constantinople, and it was he who succeeded him in the second ecumenical council at Constantinople in 381. He died soon after the opening of the council, and the emperor Theodosius, who had received him with especial distinction, caused his body to be carried to Antioch and buried with the honours of a saint. The Meletian schism, however, did not end with his death. In spite of the advice of Gregory of Nazianzus and of the Western Church, the recognition of Paulinus's sole episcopate was refused, Flavian being consecrated as Meletius's successor. The Eustathians, on the other hand, elected Evagrius as bishop on Paulinus's death, and it was not till 415 that Flavian succeeded in re-uniting them to the Church.

Meletius was a holy man, whose ascetic life was all the more remarkable in view of his great private wealth. He was also a man of learning and culture, and widely esteemed for his honourable, kindly and straightforward character. He is venerated as a saint and confessor in both the Roman Catholic and Orthodox Eastern Churches.
MELETIUS OF LYCOPOLIS—MÉLINGUE

See the article of G. F. Loof in Herzog-Hauck, Realencyklopädie (ed. 1897, Leipzig), xii. 552, and authorities there cited. MELETIUS OF LYCOPOLIS (4th century), founder of the sect known after him as the “Meletians,” or as the “Church of the Martyrs,” in the district of Thebes in Egypt. With Peter, archbishop of Alexandria, he was thrown into prison during the persecution under Diocletian. His importance is due to his refusal to receive, at least until the persecution had ceased, those Christians who during the persecutions had renounced their faith, and then repented. This refusal led to a breach with Peter, and other Egyptian bishops who were willing to grant absolution to those who were willing to do penance for their infidelity. Meletius, after regaining his freedom, held his ground and drew around him many supporters, extending his influence even so far away as Palestine. He ordained 20 bishops and encroached upon Peter’s jurisdiction. The Council of Nicaea in 325 upheld the bishops, but Meletius was allowed to remain bishop of Lykopolis though with merely nominal authority. His death followed soon after. His followers, however, took part with the Arians in the controversy with Athanasius and existed as a separate sect till the 5th century.

See Achelis in Herzog-Hauck, Realencyk. xii. (1903) 358, with the authorities there quoted, and works on Church History.

MELFI, a city and episcopal see of Basilicata, Italy, in the province of Potenza, 30 m. by rail N. of the town of that name. Melfi is picturesquely situated on the lower slopes of Monte Vulture, 1391 ft. above sea-level. Pop. (1901), 14,547. The castle was originally erected by Robert Guiscard, but as it now stands it is mainly the work of the Doria family, who obtained possession of it in 1123, and the noble cathedral which was founded in 1145 by Robert’s son and successor, Roger, has had a modern restoration (though it retains its campaniles) in consequence of the earthquake of 1851, when the town was ruined, over one thousand of the inhabitants perishing. It is the centre of an agricultural district which produces oil and wine. In the town hall is a fine Roman sarcophagus found 6 m. W. of Venosa.

Melfi does not seem to occupy an ancient site, and its origin is uncertain. By the Normans it was made the capital of Apulia in 1041, and fortified. The council held by Nicholas I. in 1059, that of Urban II. in 1089, the rebellion against Roger in 1133 and the subsequent punishment, the plunder of the town by Barbarossa in 1167, the attack by Richard, count of Acre, in 1190, and the participation of Robert Guiscard and Frederick I. in the constitutions of the kingdom of Naples, form the principal points of interest in the annals of Melfi. In 1348 Joanna I. of Naples bestowed the city on Niccolò Acciajoli; but it was shortly afterwards captured, and was held for a time by the king of Hungary, who transferred it to Conrad the Wolf. In 1392 Goffredo Marzano was made count of Melfi; but Joanna II. granted the lordship to the Caracciolo family, and they retained it for one hundred and seven years till the time of Charles V. An obstinate resistance was offered by the city to Lautrec de Foix in 1528; and his entrance within its walls was followed by the massacre, it is said, of 18,000 of its citizens.

See G. de Lorenzo, Venosa e la regione del Vulture (Bergamo, 1896).

MELICERTES, in Greek legend, the son of the Boeotian prince Athamas and Ino, daughter of Cadmus. Ino, pursued by her husband, who had been driven mad by Hera because Ino had brought up the infant Dionysus, threw herself and Melicertes into the sea from a high rock between Megara and Corinth. Both were changed into marine deities—Ino as Leucothea, Melicertes as Palaemon. The body of the latter was carried by a dolphin to the Isthmus of Corinth and deposited under a pine tree. Here it was found by his uncle Sisyphus, who had it removed to Corinth, and by command of the Nereids instituted the Isthmian games and sacrifices in his honour. There seems little doubt that the cult of Melicertes was of foreign, probably Phoenician, origin, and introduced by Phoenician navigators on the coasts and islands of the Aegean and Mediterranean. He is a native of Boeotia, where Phoenician influences were strong; at Tenedos he was propagated by the sacrifice of children, which seems to point to his identity with Melkart. The premature death of the child in the Greek form of the legend is probably an allusion to this.

The Romans identified Palaemon with Portunus (the harbour god). No satisfactory origin of the name Palaemon has been given. It has been suggested that it means the “wrestler” or “struggler” (palaëw) and is an epithet of Hercules, who is often depicted with Halieutikah (the sea), and who does not appear to be any traditional connexion between Hercules and Palaemon. Melicertes being Phoenician, Palaemon also has been explained as the “burning ford” (Baal-haman), but there seems little in common between a god of the sea and a ford.

See Apollodorus iii. 4. 3; Ovid, Metam. iv. 416–542, Fasti, vi. 485; Hyginus, Fab. 2.; Pausanias i. 44, ii. 17; Philostorus, Icones, ii. 16; articles by Toutain in Darmereau and Saglio’s Dictionnaires des antiquités et by Scylla in Roscher’s Lexicon der Mythologie; Philotheus Grecian Lexicon; R. Brown, Semitic Influences in Hellenic Mythology (1898).

MELILLA, a Spanish fortified station and penal settlement on the north coast of Morocco, south of Cape Tres Forcas and 135 m. E.S.E. of Ceuta. Pop. about 9000. The town is built on a huge rock connected with the mainland by a rocky isthmus. There is a harbour, only accessible to small vessels; the roadstead outside is safe and has deep water a mile to the east of the fortress. From the landing-place, where a mole is cut out of the rock, there is a steep ascent to the upper town, characteristically Spanish in appearance. The town is walled, and the isthmus protected by a chain of small forts. A Moorish custom-house is placed on the Spanish side of the pass near the road to the port. The town, an authorized centre of trade on the Riff coast between Tétuan and the Algerian frontier. It thus forms the entrepôt for the commerce of the Rif district and its hinterland. Goat skins, eggs and beeswax are the principal exports, cotton goods, tea, sugar and candles being the chief imports. For the period 1900–1905 the annual value of the trade was about £200,000. Melilla, the first place captured by Spain on the African mainland, was seized from the Moors in 1490. The Spaniards have had much trouble with the neighbouring tribes—turbulent Rifians, hardly subject to the sultan of Morocco. The limits of the Spanish territory round the fortress were fixed by treaties with Morocco in 1859, 1860, 1861 and 1894. In 1893 the Rifians besieged Melilla and 25,000 men had to be despatched against them. In 1908 two companies, under the protection of El Roghi, a chieftain then ruling the Rif region, started mining lead and iron some 15 m. from Melilla and a railway to the mines was begun. In October of that year the Rifians revolted from the Roghi and raided the mines, which remained closed until June 1909. On the 7th of July the workmen were again attacked and several of them killed. Severe fighting between the Spaniards and the tribesmen followed. The Rifians having submitted, the Spaniards, in 1910, restarted the mines and undertook harbour works at Mar Chica.

MÉLINE, FÉLIX JULES (1838— ), French statesman, was born at Remiremont on the 20th of May 1838. Having adopted the law as his profession, he was chosen a deputy in 1872, and in 1870 he was for a short time under-secretary to the minister of the interior. In 1880 he came to the front as the leading spokesman of the party which favoured the protection of French industries, and he had a considerable share in fashioning the protectionist legislation of the years 1890–1902. From 1883 to 1885 Méline was minister for agriculture, and in 1886–1888 he was president of the Chamber of Deputies. In 1896 he became premier (président du conseil) and minister for agriculture, offices which he vacated in 1898. At one time he edited La République française, and after his retirement from public life he wrote Le Retour à la terre et la surproduction industrielle, tout en faveur de l’agriculture (1903).

MÉLINIE, ÉTIENNE MARIN (1808–1873), French actor and sculptor, was born in Caen, the son of a volunteer of 1792. He early went to Paris and obtained work as a sculptor on the church of the Madeleine, but his passion for the stage soon led him to join a strolling company of comedians. Finally chance gave him an opportunity to show his talents, and at the Porte Saint Martin he became the popular interpreter of romantic
MELIORISM—MELLITIC ACID

95
drama of the Alexandre Dumas type. One of his greatest successes was as Benvenuto Cellini, in which he displayed his ability both as an actor and as a sculptor, really modelling, before the eyes of the audience a statue of Hebe. He sent a number of statuettes to the various exhibitions, notably one of Gilbert Louis Duprez as William Tell. Melinge’s wife, Théodore Thiesset (1813-1886), was the actress selected by Victor Hugo to create the part of Gauhumara in Burgraves at the Comédie Française, where she remained ten years.

See Dumas, Une Vie d’artiste (1854).

MELIORISM (Lat. melior, better), in philosophy, a term assigned to that view of things which believes that at present the sum of good exceeds the sum of evil and, in the future, good will continually gain upon evil. The term is said to have been invented by George Eliot to express a theory mediating between optimism and pessimism. The pragmatic movement in philosophy which puts stress upon the duty and value of effort is naturally favourable to the melioristic view: the best things that have been said recently in favour of it are found in books such as William James’s Pragmalism.

MELISSUS OF SAMOS, Greek philosopher of the Eleatic School (q.v.), was born probably not later than 470 B.C. According to Diogenes Laërtius, i. 24, he was not only a thinker, but also a political leader in his native town, and was, in common with the rest of the Eleatics, executed by Croesus in 468 B.C. The same author says he was a pupil of Parmenides and of Heraclitus, but the statement is improbable, owing to discrepancy in dates. His works, fragments of which are preserved by Simplicius and attested by the evidence of Aristotle, are devoted to the defence of Parmenides’ doctrine. They were written in Ionic and consist of long series of argument. Being, he says, is eternal. It cannot have had a beginning because it cannot have begun from nothing (cf. ex nihilo nihil), nor from being (ex yado aon ovoi kai aon yeivnoi). It cannot suffer destruction; it is impossible for being to become not-being, and if it became another being, there would be no destruction. According to Simplicius (Physica, f. 22b), he differed here from Parmenides in distinguishing being and absolute being (a oikos aoros). He goes on to show that eternal being must also be unlimited in magnitude, and, therefore, one and unchangeable. Any change whether from internal or external source, he says, is unthinkable; the One is unvarying in quantity and in kind. There can be no division inside this unity, for any such division implies space or void; but void is nothing, and, therefore, is not. It follows further that being is incorporeal, inasmuch as all body has size and parts. The fundamental difficulty underlying this logic is the paradox more clearly expressed by Zeno and to a large extent represented in almost all modern discussion, namely, that the evidence of the senses contradicts the intellect. Abstract argument has shown that change in the unity is impossible; yet the senses tell us that hot becomes cold, hard becomes soft, the living dies, and so on. From a comparison of Melissus with Zeno of Elea, it appears that the spirit of dialectic was already tentatively at work, though it was not conscious of its own power. Neither Melissus nor Zeno seems to have observed that the application of these destructive methods struck at the root not only of multiplicity but also of the One whose existence they maintained. The weapons which they forged in the interests of Parmenides were to be used with equal effect against themselves.

See Ritter and Proller. §§ 159-166; Brandis, Commentationum eleaticarum, p. 185; Mullach, Aristotelis de Melisco Xenophaneae Gorgiae: Pabst, De Melissi sommi fragmentis (Bonn, 1889), and histories of philosophy.

MELITO, bishop of Sardis, a bardic writer of the 2nd century, mentioned by Eusebius (Hist. Eccl. iv. 21) along with Hegesippus, Dionysius of Corinth, Apollinaris of Hierapolis, Irenaeus, and others, his contemporaries, as a champion of orthodoxy and upholder of apostolic tradition. Of his personal history nothing is known, and of his numerous works (which are enumerated—with quotations—by Eusebius) only a few fragments are extant. They included an Apologia addressed to Antoninus some time between a.d. 169 and 180, two books relating to the paschal controversy, and a work entitled Ἑσοπαίαν (an imitation of the Old Testament), which contained a Christian list of “the books of the Old Covenant.” It excludes Esther, Nehemiah and the Apocrypha. The fragments have been edited with valuable notes by Routh (Reliquiae sacrae, vol. i., 1874). These are sufficient to show that Melito was an important figure in Asia Minor and took much part in the paschal, Marcionite and Montanist controversies.

It seems more than doubtful whether the Apologia of Melito “the Philosopher,” discovered in a Syriac translation by Henry Tattam (1789-1868), and subsequently edited by W. Cureton and W. Renan, ought to be attributed to this writer and not to another of the same name. The Καίσ (clavis), edited by Pitra-Renan, is a much later Latin collection of mystical explanations of Scripture.

MELKSHAM, a market town in the Western parliamentary division of Wiltshire, England, 95 ½ m. W. of London by the Great Western railway. Pop. of urban district (1901), 2450. It lies in a valley sheltered by steep chalk hills on the east, its old-fashioned stone houses lining a single broad street, which crosses the Upper Avon by a bridge of four arches. The church preserves some remnants of Norman work and a Perpendicular south chapel of rare beauty. Melksham possesses cloth-mills where coco-nut fibre and hair cloth are woven, flour-mills and dye-works.

On the discovery of a saline spring in 1816, baths and a pump-room were opened, but although two other springs were found later, the attempt to create a fashionable health resort has failed. The church, a long-deer forest was often visited by Edward L. Lacock Abbey, 3 m. distant, was founded in 1332 for Austin canoneses, and dissolved in 1539. Portions of the monastic buildings remain as picturesque fragments in and near the modern mansion called Lacock Abbey.

MELLE, a town of western France, capital of an arrondissement in the department of Deux-Sèvres, on the left bank of the Béronne, 21 m. E.S.E. of Niort by rail. Pop. (1906), 2231. Melle has two churches in the Romanesque style of Poitou, St Peter and St Hilaire, the latter ornamented with sculptured arcading. The hospital has a richly carved doorway of the 17th century. The church of St Savinien (11th century) serves as a prison. The town has trade in farm-produce, mules and other live stock; distilling is carried on. Melle (Metallum) derives its name from the lead mine worked here during the Roman occupation and in the early middle ages. At the latter period it had a mint. In later times it was a possession of the counts of Maine.

MELONIC ACID (benzene hexacarboxylic acid), C6(CO2H)6, was first discovered in 1799 by M. H. Klaproth in the mineral honeystone, which is the aluminium salt of the acid. The acid may be prepared by warming honeystone with ammonium carbonate, boiling off the excess of the ammonium salt and adding ammonia to the solution. The precipitated alumina is filtered off, the filtrate evaporated and the ammonium salt of the acid purified by recrystallization. The ammonium salt is then converted into the lead salt by precipitation with lead acetate and the lead salt decomposed by sulphuretted hydrogen.

The acid may also be prepared by the oxidation of pure carbon, or of hexamethylene benzene, in the cold, by alkaline potassium permanganate (F. Schulze, Ber., 1871, 4, p. 502); C. Friedel and J. M. Crafts, Ann. chem. phys. 1884 [6], p. 470). It crystallizes in fine silky needles and is soluble in water and alcohol. It is a very stable compound, chlorine, concentrated nitric acid and hydrochloric acid having no action on it. Its decomposition on distillation, into carbon dioxide and pyromellitic acid, C6H2O4: when distilled with lime it gives carbon dioxide and benzene. Long digestion of the acid with excess of phosphorus pentachloride results in the formation of the homologous compound, which crystallizes in needles, melting at 190° C. By heating the ammonium salt of the acid to 150-160° C. as long as ammonia is evolved, a mixture of paramide (mellimide), C6(CO2NH)6 and ammonium euctrahe is obtained. The mixture may be separated by dissolving out the ammonium euctrahe with water. Paraide is a white amorphous powder, insoluble in water and alcohol.
MELLITUS—MELODY

MELLITUS (d. 624), bishop of London and archbishop of Canterbury, was sent to England by Pope Gregory the Great in 601. He was consecrated by St Augustine before 604, and a church was built for him in London by Aethelberht, king of Kent; this church was dedicated to St Paul, and Mellitus became first bishop of London. About ten years later the East Saxons reverted to heathenism and the bishop was driven from his see. He took refuge in Kent and then in Gaul, but soon returned to England, and in 610 became archbishop of Canterbury in succession to Laurentius. He died on the 24th of April 624.

MELLONI, MACEDONIO (1798-1854), Italian physicist, was born at Parma on the 11th of April 1798. From 1824 to 1831 he was professor at Parma, but in the latter year he was compelled to escape to France, having taken part in the revolution. In 1839 he went to Naples and was soon appointed director of the Vesuvius observatory, a post which he held until 1848. Mellonì received the Rumford medal of the Royal Society in 1834. In 1835 he was elected correspondent of the Paris Academy, and in 1850 a foreign member of the Royal Society. He died at Portici near Naples of cholera on the 11th of August 1854. Mellonì's reputation as a physicist rests especially on his discoveries in radiant heat, made with the aid of the thermo-multiplier or combination of thermopile and galvanometer, which, soon after the discovery of thermoelectricity by T. J. Seebeck, was employed by him jointly with L. Nobili in 1831. His experiments were especially concerned with the power of transmitting dark heat possessed by various substances and with the changes produced in the heat rays by passage through different materials. Substances which were comparatively transparent to heat he designated by the adjective "diathermic," the property being "diathermanité," while for the heat-tint or heat-coloration produced by passage through different materials he coined the word "diathermanie." In English, however, the terms were not well understood, and "diathermanity" was generally used as the equivalent of "diathermanité." In consequence Mellonì about 1841 began to use "diathermic" in place of "diathermané," "diathermásie" in place of "diathermanité," and "thermocorse" for "diathermanie." His most important book, La thermocorse ou la coloration calorifique (vol. i., Naples, 1850), was unfinished at his death. He studied the reflection and polarization of radiant heat, the magnetism of rocks, electrostatic induction, daguerrotypes, &c.

MELODRA (a coined word from Gr. μδος, music, and δραμα, action), the name of several species of dramatic composition. As the word implies, "melodrama" is properly a dramatic mixture of music and action, and was first applied to a form of dramatic musical composition in which music accompanied the spoken words and the action, but in which there was no singing. The first example of such a work has generally been taken to be the Pygmalion of J. J. Rousseau, produced in 1775. This is the source of romantic dramas depending on sensational incident with exaggerated appeals to conventional sentiment rather than on play of character, and in which dramatis persona follow conventional types—the villain, the hero wrongfully charged with crime, the persecuted heroine, the adventurer, &c. At first the music was of some importance, forming practically a running accompaniment suitable to the situations—but this has gradually disappeared, and, if it remains, is used mainly to emphasize particularly strong situations, or to bring on or off the stage the various principal characters. Such plays first became popular in France at the beginning of the 19th century. One of the most prolific writers of melodramas at that period was R. C. de Pixerecourt (1777-1844). The titles of some of his plays give a sufficient indication of his character; e.g. Victor, ou l'enfant de leur hérédité (1797); Carlina, ou l'enfant du mystère (1801); Le Monastère abandonné, ou la malédiction paternelle (1816). Another form of melodrama came from the same source, but developed on lines which laid more emphasis on the music, and is of some importance in the history of opera. Probably the first of this type is to be found in Georg Benda's Ariadne auf Naxos (1774). The most familiar of such melodramas is Gay's Beggar's Opera. In these the dialogue is entirely spoken. In true opera the spoken dialogue was replaced by recitative. It may be noticed that the speaking of some parts of the dialogue is not sufficient to class an opera as a "melodrama" in this sense, as is proved by the spoken grave-digging scene, accompanied by music, in Fidelio, and the incantation scene in Der Freischütz. To this the English term "declaration" is usually applied; the Germans use Melodram. But see Opera.

MELODY (Gr. μελός, a choral song, from μελός, tune, and ός, song). In musical philosophy and history the word "melody" must be used in a very abstract sense, as that aspect of music which is concerned only with the pitch of successive notes. Thus a "melodic scale" is a scale of a kind of music that is not based on an harmonic system; and thus we call ancient Greek music "melodic." The popular conception of "melody" is that of a "single" or "a line," and from being a primitive conception that there are few instances of such melodrama in recorded music before the 17th century; and even folk-songs, unless they are of recent origin, deviate markedly from the criteria of tunefulness. The modern conception of melody is based on the interaction of every musical category. For us a melody is the surface of a series of harmonies, and an unaccompanied melody so far implies harmony that if it so behaves that simple harmonies expressing clear key-relationships would be difficult to find for it, we feel it to be strange and vague. Again, we do not feel music as melodic unless its rhythm is symmetrical; and this, taken together with the harmonic rationality of modern melody, brings about an equally intimate connexion between melody on a large scale and form on a small scale. In the article on Sonata Forms it is shown that there are gradations between the form of some kinds of single melody like "Bartholomew Allegro," and the other forms of the suite, and then, again, gradations between these and the true sonata forms with their immense range of expression and development. Lastly, the element that appears at first sight most strictly melodic, namely, the rise and fall of the pitch, is intimately connected by origin with the nature of the human voice, and in later forms is enlarged fully as much by the characteristics of instruments as by parallel developments in rhythm, harmony and form. Thus modern melody is the musical surface of rhythm, harmony, form and instrumentation; and, if we take Wagnerian Leitmotive into account, we may as well add drama to the list. In short, melody is the surface of music.

We may here define a few technicalities which may be said to come more definitely under the head of melody than any other; but first HARMONIES and RHYTHM, and then, also HARMONIES and RHYTHM, and then, also HARMONIES and RHYTHM. Thus a good familiar example of a simple melody which, as written by the composer, would need two voices to sing it, is that
which begins the second subject of Beethoven's Waldstein Sonata (Op. 53, first movement, bars 35-42, where at the third bar of the melody a lower voice enters and finishes the phrase).

4 (a) *Conjunct movement* is the movement of melody along adjacent degrees of the scale. A large proportion of Beethoven's melodies are conjunct (see Ex. 2, fig. B).

4 (b) *Disjunct movement*, the opposite of conjunct, tends, though by no means always, to produce *arpeggio* types of melody, i.e. melodies which move up and down the notes of a chord. Certain types of such melody are highly characteristic of Brahms; and Wagner, whose melodies are almost always of instrumental origin, is generally disjunct in diatonic melody and conjunct in chromatic (Ex. 2, fig. C, is a disjunct figure not forming an arpeggio).

For various other melodic devices, such as inversion, augmentation and diminution, see CONTRAPUNTAL FORMS.

We subjoin some musical illustrations showing the treatment of figures in melody as a means of symmetry (Ex. 1), and development (Ex. 2-7), and (Ex. 8-13) some modern melodic transformations, differing from earlier methods in being immediate instead of gradual.

MELON—MELORIA

MELON (Late Lat. melo, shortened form of Gr. μηλον, a kind of gourd; μηλος, melope, and μέλος, ripe), Cucumis melo, a polymorphic species of the order Cucurbitaceae, including numerous varieties.¹ The melon is an annual trailing herb with palmately-lobed leaves, and bears tendrils by means of which it is readily trained over trellises, &c. It is monocious, having male and female flowers on the same plant; the flowers have deeply five-lobed campanulate corollas and three stamens. Naudin observed that in some varieties (e.g. of Cantaloupes) fertile stamens sometimes occur in the female flowers. It is a native of south Asia "from the foot of the Himalayas to Cape Comorin,"² where it grows spontaneously, but is cultivated in the temperate and warm regions of the whole world. It is variable both in diversity of form and habit, but much more so in the fruit, which in some varieties is no larger than an olive, while in others it rivals the gourd (Cucurbita maxima). The fruit is globular, ovoid, spindle-shaped, or serpent-like, netted or smooth-skinned, ribbed or furrowed, variously coloured externally, with white, green, or orange flesh when ripe, scented or scentless, sweet or insipid, bitter or even nauseous, &c. Like the gourd, the melon undergoes strange metamorphoses by crossing its varieties, though the latter preserve their characters when alone. The offshoot of all crossings are fertile. As remarkable cases of sudden changes produced by artificially crossing races, M. Naudin records that in 1859 the offshoot of the wild melons m. sauvage de l'Inde (C. melo agrarius) and m. s. d'Afrique, le petit m. de Figari bore different fruits from their parents, the former being ten to twelve times their size, ovoid, white-skinned, more or less scented, and with reddish flesh; though another individual bore fruits no larger than a nut. The offshoot of m. de Figari after being crossed bore fruits of the serpent-melon. On the other hand, the serpent-melon was made to bear ovoid and reticulated fruit.

Naudin thinks it probable that the culture of the melon in Asia is as ancient as that of all other alimentary vegetables. The Egyptians grew it, or at least inferior races of melon, which were either indigenous or introduced from Asia. The Romans and doubtless the Greeks were familiar with it, though some forms may have been described as cucumbers. Columella seems to refer to the serpent-melon in the phrase ut coluber . . . ventre cubat fleso. Pliny describes them as pepones (xiii. 23 to xx. 6) and Columella as melones (xi. 2, 53). The melon began to be extensively cultivated in France in 1629, according to Olivier de Serres. Gerard (Herball, 177) figured and described in 1597 several kinds of melons or pempions, but he has included gourds under the same name.

The origin of some of the chief modern races, such as "Cantaloup," "Dudaim," and probably the netted sorts, is due to Persia and the neighbouring Caucasian regions. This is first of these was brought to Rome from Armenia in the 16th century, and supplies the chief sorts grown for the French markets; but many others are doubtless artificial productions of west Europe.

The water-melon (Citrullus vulgaris) is a member of a different genus of the same order. It has been cultivated for its cool refreshing fruit since the earliest times in Egypt and the Orient, and was known before the Christian era in southern Europe and Asia.

The melon requires artificial heat to grow it to perfection, the rock and cantaloup varieties succeeding with a bottom heat of 70° and an atmospheric temperature of 75°, rising with sun heat to 80°, and the Persian varieties requiring a bottom heat of 75°, gradually increasing to 80°, and an atmospheric temperature ranging from 75° to 80° when the fruit is swelling; as much heat as the plants can bear being allowed at all times. The melon grows best in rich loamy soil, somewhat heavy, with which a little well-dug dung, especially that of pigeons or fowls, should be used, in the proportion of one-fifth of the soil for each. Melons are grown on hotbeds of fermenting manure, when the soil should be about a foot in thickness, or in pits heated either by hot water or fermenting matter, or in houses heated by hot water, in which case the soil bed should be 15 to 18 in. thick. All fermenting materials should be well prepared, and, since the heat has to be kept up by linings, it is a good plan to introduce one or two layers of faggots in building up the bed. A mixture of dung and leaves gives a more subdued but more durable heat.

The ordinary preparation for sowing the first crop, as well-flavoured fruits can scarcely be looked for before May. The seeds may be sown singly in 3-in. pots in a mixture of leaf-mould with a little loam, the pots being plunged in a bottom heat of 80° and as near the glass as possible, in order that the young plants may not be drawn up. The hill or ridge of soil should be about a foot in thickness, the rest of the surface being afterwards made up nearly to the same level. If the fruiting-bed is not ready when the roots have nearly filled the pots, the plants should be moved into 4-inch pots, for they must not get starved or pot-bound. Two or three plants are usually planted in a mound or ridge of soil placed in the centre of each light, and the rest of the surface is covered with earth as soon as the roots have made their way through the mound. The melon being one of those plants which produce distinct male and female flowers, it is necessary to its fertility that both sexes should be produced on one and the same plant. Melons may be propagated by seed, either naturally by insect agency, or artificially by the cultivator's manipulation, be conveyed to the stigma of the female flower; this setting of the fruit is often done by stripping a male flower of its anthers and pistil, and placing it on the stigma of the female flower. After the fruit has set and has grown to the size of an egg, it should be preserved from contact with the soil by placing it on a piece of tile or slate; or if grown on a trellis by a little swinging wooden shelf, just large enough to hold it. In either case the fruit should be lifted periodically to permit water to drain away. Before the process of ripening commences, the roots should have a sufficient supply of moisture, so that none may be required from that time until the fruit is cut.

Melons are liable to the attack of red spider, which are best removed by syringing with rain-water, and prevented by keeping a fairly humid atmosphere; green or black fly should also be watched for and removed by fumigation with tobacco smoke or by "smoke-bag." The varieties of melon are continually receiving additions, and as new varieties spring into favour, so the older ones drop out of cultivation. A great deal depends on getting the varieties true to type, and on the ability to get cross-fertilized by insect agency. Some of the best at present are: Scarlet-fleshed.—Blenheim Orange, Frogmore Orange, Inivincible, Sutton's Scarlet, and Triumph.

White-fleshed.—Longsdon White, Hero of Locking, Longleaf Perfection, Royal Favor, and Truffulote.

Green-fleshed.—British Queen, Epicure, Exquisite, Monarch, Ringleader.

The market-gardeners round Paris and other parts of France cultivate varieties of Cantaloup melon known as the Prescott hâtifie a chassie and Prescott fond blanc—both excellent in flavour. The plants are grown in frames on hotbeds, and only one large fruit is allowed to mature on each plant; if secured early in the season, 25 to 35 francs can be obtained for each fruit in the Paris markets; later fruits, however, drop down to 2 francs each, or even less when there is a glut (see J. Weathers, French Market-Gardening).

MELORIA, a rocky islet, surrounded by a shoal, almost opposite Leghorn. It was the scene of two naval battles of the
middle ages. The first, on the 3rd of May 1241, was fought between the fleet of the emperor Frederick II. Hohenstaufen, surnamed Stupor Mundi, in alliance with Pisa, against a Genoese squadron bringing a number of English, French and Spanish prelates to attend the council summoned to meet at the Lateran by Gregory IX. Three Genoese galleys were sunk and twenty-two taken. Several of the prelates perished, and many were carried prisoners to the camp of the emperor. The second, fought on Sunday the 6th of August 1284, was of higher historical importance. It was a typical medieval sea-fight, and accomplished the ruin of Pisa as a naval power. The long rivalry of that city and of Genoa had broken out for the last time in 1282, the immediate cause being the incompatible claims of the two cities to sovereignty over the islands of Sardinia and Corsica. The earlier conflicts of the war in 1282, 1283 and the spring of 1284, had been unfavourable to Pisa. Though the city was united with the Catalans and with Venice in hostility to Genoa, and though it had chosen a Venetian, Alberto Morosini, as its Podesta, it received no help from either. The Genoese, who had the larger and more efficient fleet, sent their whole power against their enemy. When the Genoese appeared off Meloria the 12th of August 1284, the river Porto Pisano was held by the Pisans, and they arrived at the port of the city. The Pisan fleet represented the whole power of the city, and carried members of every family of mark and most of the great officers of state. The Genoese, desiring to draw their enemy out to battle, and to make the action decisive, arranged their fleet in two lines abreast. The first was composed according to Agostino Giustianini of fifty-eight galleys, and eight pantalé, a class of light galleys of eastern origin named after the province of Pamphylia. Uberto Doria, the Genoese admiral, was stationed in the centre and in advance of his line. To the right were the galleys of the Spinola family, and four of the eight "companies" into which Genoa was divided—Castello, Piazzaalunga, Macagnano and Son Lorenzo. To the left were the galleys of the Dorias, and of the other four companies, Porta, Soniglia, Porta Nuova and Il Borgo. The second line of twenty galleys, under the command of Benedetto Giacaria (or Zaccharie) was placed so far behind the first that the Pisans could not see whether it was made up of war-vessels or of small craft meant to act as tenders to the others. Yet it was near enough to strike in and decide the battle when the action had begun. The Pisans, commanded by the Podesta Morosini and his lieutenants Ugolino della Gerhardesca and Andreotto Saraceno, came out in a single body. It is said that while the archbishop was blessing the fleet the silver cross of his archiepiscopal staff fell off, but that the omen was disregarded by the irreverence of the Pisans, who declared that if they had the wind they could do without divine help. They advanced in line abreast to meet the first line of the Genoese, fighting according to the medieval custom to ram and board. The victory was decided for Genoa by the squadron of Giacaria which fell on the flank of the Pisans. Their fleet was nearly annihilated, the Podesta was taken, and Ugolino fled with a few vessels. As Pisa was also attacked by Florence and Lucca it could never recover the disaster. Two years later Genoa took Porto Pisano, and filled up the harbour. The count Ugolino was afterwards starved to death with several of his sons and grandsons in the manner made familiar by the 3rd canto of Dante's Inferno.

MELOS (mod. Milo), an island of the Aegean Sea (Cyclades group), at the S.W. corner of the archipelago, 7.5 m. due E. from the coast of Laconia. From E. to W. it measures about 14 m., from N. to S. 8 m., and its area is estimated at 52 sq. m. The greater portion is rugged and hilly, culminating in Mount Elia on the west (1968 ft.). Like the rest of the cluster, the island is of volcanic origin, with tuff, trachyte and obsidian among its ordinary rocks. The natural harbour, which, with a depth diminishing from 70 to 30 fathoms, strikes in from the north-west so as to cut the island into two fairly equal portions, with an isthmus not more than 12 m. broad, is the principal crater. In one of the caves on the south coast the heat is still great, and on the eastern shore of the harbour there are hot sulphur springs. Sulphur is found in abundance on the top of Mount Kalamo and elsewhere. In ancient times the altar of Melos was reckoned next to that of Egypt (Plyn. xxxv. 15 [52]), and milestones, salt (from a marsh at the east end of the harbour), and gypsum are still exported. The Melian earth (99 Mpsd) was employed as a pigment by ancient artists. Orange, olive, cypress and arbutus trees grow throughout the island, which, however, is too dry to have any profusion of vegetation. The vine, the cotton plant and barley are the main objects of cultivation. Pop. (1907), 4864 (commune), 12,774 (province).

The harbour town is Adamanta; from this there is an ascent to the plateau above the harbour, on which are situated Plaka, the chief town, and Kastro, rising on a hill above it, and other villages. The ancient town of Melos was nearer to the entrance of the harbour than Adamanta, and occupied the slope between the village of Trypete and the landing-place at Klima. Here is a theatre of Roman date and some remains of town walls and other buildings, one with a fine mosaic excavated by the British school at Athens in 1896. Numerous fine works of art have been found on this site, notably the Aphrodite of Melos in the Louvre, the Venus of Milo, and the Apollo of Melos, the archaic Apollo in Athens. The position of Melos, between Greece and Crete, and its possession of obsidian, made it an important centre of early Aegean civilization. At this time the chief settlement was at the place now called Phylakopi, on the north-east coast. Here the excavations of the British school cleared many houses, including a palace of "Myceanaean" type; there is also a town wall. Part of the site has been washed away by the sea. The antiquities found were of three main periods, all preceding the Mycenean age of Greece. Much pottery was found, including examples of a peculiar style, with decorative designs, mostly floral, and also considerable deposits of obsidian. There are some traditions of a Phoenician occupation of Melos. In historical times the island was occupied by Dorians from Laconia. In the 6th century it again produced a remarkable series of vases, of large size, with mythological subjects and orientalizing ornamentation (see GREEK ART, fig. 9), and also a series of terra-cotta reliefs.

Though Melos inhabitants sent a contingent to the Greek fleet at Salamis, it held aloof from the Athenian, and sought to remain neutral during the Peloponnesean War. But in 416 B.C. the Athenians, having attacked the island and compelled the Melians to surrender, slew all the men capable of bearing arms, made slaves of the women and children, and introduced 500 Athenian colonists. Lysander restored the island to its Dorian possessors, but it never recovered its former prosperity. There were many Jewish settlers in Melos in the beginning of the Christian era, and Christianity was early introduced. During the Frankish period the island formed part of the duchy of Naxos, except for the four years (1341-1383) when it was a separate lordship under Marco Sanudo and his daughter.

Antimelos or Antimilo, 53 m. north-west of Milo, is an uninhabited mass of trachyte, often called Eremomil or Desert Melos. Kimolos, or Argenteira, less than 1 m. to the north-east, was famous in antiquity for its figs and fuller's earth (Kuμαλία γιφ), and contained a considerable city, the remains of which cover the cliff of St. Andrews. Polimnos, Polibos or Polin (anc. Polynagros) lies rather more than a mile south-east of Kimolos. It was the subject of dispute between the Melians and Kimolians. It has long been almost uninhabited.

MELOZZO DA FORLÌ (c. 1438-1494), Italian painter, the first who practised foreshortening with much success, was born at Forlì about 1438; he came, it is supposed, of a wealthy family named Ambrosi. In all probability, Melozzo studied painting under Piero de' Franceschi, of Borgo St Sepolcro; he seems also to have been well acquainted with Giovanni Santi, the father of
Melrose Abbey, the town has become residential and a holiday resort. There is a hydropathic establishment on Skirmish Hill, and near the abbey are the remains of a battle fought in 1526, in which the Scots defeated the English. Trade is almost wholly agricultural. The main streets run from the abbey to the market, which is located in the center of the town. It is surrounded by orchards and gardens, and the market is held on the first Saturday of every month.

The original Columban monastery was founded in the 7th century at Old Melrose, about 25 m. to the east, in the loop of a great bend of the Tweed. It was colonized by Lindisfarne, Eata, a disciple of Aidan, being the first abbot (651), and Boisil and Cuthbert being prior here. It was burned by Kenneth Macalpine in 839 during the wars between St. Cuthbert and Saxons, and, though rebuilt, was deserted in the middle of the 11th century. The chapel, dedicated to St. Cuthbert, continued for a period to attract many pilgrims, but this usage gradually declined and the building was finally destroyed by English invaders. Meanwhile in 1136 David I. and founded an abbey dedicated to the Virgin, a little higher up the Tweed, the first Cistercian settlement in Scotland, with monks from Melrose in the form of a conventional house. The abbey, as frequented and in 1322 destroyed by Edward II. Rebuilt, largely by means of a gift of Robert Bruce, it was nearly burned down in 1385 by Richard II. Erected once more, it was reduced to ruin by the earl of Hertford (afterwards the Protector Somerset) in 1354. Later the Reformers dismantled much of what was left. The adaptation of part of the nave to the purposes of a parish church and the use of the building as a quarry did further damage. The ruins, however, now the property of the Duke of Buccleuch, are carefully preserved. Of the conventual buildings apart from the church nothing has survived but a fragment of the cloister with a richly-carved round-headed doorway and some fine arcading. The abbey, cruciform, is in the Decorated and Perpendicular styles, with pronounced French influence, due probably to the master mason John Morow, or Morreau, who, according to an inscription on the south transept wall, was born in Paris. The south front is still beautiful. The west front and a large portion of the north half of the nave and aisle have perished, but the remains include the rest of the nave, the two transepts, the chancel and choir, the arch between the nave and and the temple at the east end. From east to west it measures 258 ft., the nave is 60 ft. wide and the transepts from north to south is 115 ft. The nave had an aisle on each side, the north noticeably the narrower, the south furnished with eight chapels, one in each bay. Both transepts contained an eastern aisle, and the chanels a square chapel at its west end on each side. Over the south transept aisle, which was the chapel of St. Bridget, is the clerestory passage, which ran all round the church. The choir extended westwards for three bays beyond the tower and terminated in a stone rood-screen. Sir Walter Scott has immortalized the east window, in The Lay of the Last Minstrel, but the south window with its flowing tracery is even finer. In the carving of windows, aisles, cloister, capitals, bosses and doorheads no design is repeated. The heart of Robert Bruce was buried at the high altar, and in the chancel are the tombs of Sir William Douglas, the Knight of Liddesdale (1300-1353), James 2nd earl of Douglas (1358-1388), the victor of Otterburn; Alexander II.; and Michael Scott "the Wizard" (1175-1234)—though some authorities say that this is the tomb of Sir William Lamont, the 1st earl of Moray (1344). At the door leading from the north transept to the sacristy is the grave of Joanna (d. 1238), queen of Alexander II.

The muniments of the abbey, preserved in the archives of the earl of Roxburghe, were edited by Coates Innes for the Bannatyne Club and published in 1837 under the title Liber scabriae Marie de Melros. Among the documents is one of the earliest specimens of the Scots dialect. The Chronicles of Malros, preserved among the Cotton MSS., was printed at Oxford in 1684 by William Fulman and by the Bannatyne Club in 1835 under the editorship of John Stevenson.
MELTON MOWBRAY—MELVILLE, ANDREW

101

MELTON MOWBRAY, a market town in the Melton parliamentary division of Leicestershire, England, pleasantly situated in a fertile vale, at the confluence of the Wreake and the Eye. Pop. of urban district (1901), 7,454. It is 105 m. N.N.W. from London by the Midland railway, and is served by a joint branch of the London & North Western and Great Northern railways. The church of St Mary, a fine cruciform structure, Early English and later, with a lofty and richly ornamented central tower, was enlarged in the reign of Elizabeth. Melton is the centre of a celebrated hunting district, in connexion with which there are large stables in the town. It is known for its pork pies, and has a trade in Stilton cheese. There are breweries and tanneries and an important cattle market. There are blast furnaces in the adjoining parish of Asfordby for the smelting of the abundant supply of iron ore in the district. During the Civil War Melton was in February 1644 the scene of a defeat of the parliamentary forces by the royalists. It is the birthplace of John Henley the orator (1692–1759).

MELUN, a town of northern France, capital of the department of Seine-et-Marne, situated north of the forest of Fontainebleau, 28 m. S.S.E. of Paris by rail. Pop. (1906), 11,210. The town is divided into three parts by the Seine. The principal portion lies on the slope of a hill on the right bank; on the left bank is the most modern quarter, while the old Roman town occupies an island in the river. On the island stands the Romanesque church of Notre-Dame (11th and 12th centuries), formerly part of a nunnery, the site of which is occupied by a prison. The other public buildings are on the right bank of the river. Of these, the most striking is the church of St Apaix, an irregularly shaped structure of the 15th and 16th centuries, on the apse of which may be seen a modern medallion in bronze, the work of the sculptor H. Chapu, representing Joan of Arc as the liberator of Melun. The hôtel-de-ville (1847)—in the construction of which an old mansion and turret have been utilized—and the tower of St Bartholomew of the 16th and 18th centuries are also of interest. In the courtyard of the former there is a monument to Jacques Amyot, the translator of Plutarch, who was born at Melun in 1513. Among the rich estates in the neighbourhood the most remarkable is the magnificent château of Vaux-le-Vicomte, which belonged to Nicholas Fouquet, intendant of finances under Louis XIV. Melun is a market for grain and farm produce, and its industries include brewing, tanning, distilling, sawing and the manufacture of agricultural implements, clogs, fur garments, lime, cement and plaster.

In Caesar’s Gallic wars Melun (Melodunum) was taken by his lieutenant Labienus, in order to facilitate the attack of Lutetia by was pillaged by the Normans, and afterwards became the favourite residence of the first kings of the race of Capet; Robert and Philip I. both died here. In 1359 Melun was given up by Jeanne of Navarre to her brother, Charles the Bad, but was reanimated by the dauphin Charles and Bertrand Dugueclin. In 1428 Melun made an heroic resistance to Henry V. of England and his ally the duke of Burgundy. Ten years later the people of Melun, with the help of Joan of Arc, drove out the English. It was occupied by the League in 1568, and reanimated by Henri de Bourbon, Duke of Guise.

MÉLUSINE, the tutelary fairy of the house of Lusignan, was the eldest daughter of the fairy Pessine, to avenge whose wrongs she shut up her father in a mountain in Northumberland. For this she was condemned to be metamorphosed every Saturday into a woman-serpent—that is, to be a serpent from the hips downwards. She might, however, be eventually saved from this punishment if she could find a husband who would never see her on a Saturday. Such a husband was found in Raymond, nephew of the count of Poitiers, who became rich and powerful through the machinations of his wife. She built the castle of Lusignan and many other of the family fortresses. When at length her husband gave way to his curiosity, and saw her taking the bath of purification on a Saturday she flew from the castle in the form of a serpent. Thenceforward the death of a member of the house of Lusignan was heralded by the cries of the fairy serpent. "Fousser des cris de Mélusine" is still a popular saying.

This history is related at length, with the adventures of Mélusine’s numerous progeny, by Jean d’Arras, in his Chronique de la princesse, written in 1387 at the desire of John, duke of Berry, for the amusement of the duke and of his sister Marie of France, duchess of Bar. It is one of the most charming of the old prose romances in manner and style, and is natural in spite of the free use of the marvellous. An attempt has been made by Jules Baudot in Les Princesse Yolande et les duc de Bar (Paris, 1900) to make it a roman à clef and to identify the personages. Mélusine, Mélusine or Mélusine is, however, simply the spirit of the fountain of Lusignan, and the local Poitevin myth is attached to the origin of the noble house. The etymology of the word has been variously and fancifully given. Some writers have supposed Mélusine to be a corruption of mère Lucina, the deity invoked in child-birth. She has been identified with Mélisende, widow of a king of Jerusalem, and with Mervani, wife of Geoffrey de Lusignan.

The Méluсинe of Jean d’Arras was printed by Adam Steinschaber at Augsburg in 1478, and has been reprinted many times in the 16th and 17th centuries. It has been translated into Spanish, English, German and Flemish. Modern editions are by J. C. Brunet (Paris, 1854), and by E. Lecesne for the Académie d’Arras (Arras, 1888). The English translation was edited from a unique MS. in the British Museum by A. K. Donald for the E.E.T.S. (1895). The tale was versified in the 14th century by a poet called Coultrude, whose poem was published in 1854 by Franciscque Michel. See also de Baudot, L’Etymologie de Mélusine (Dijon, 1888); S. Baring-Gould, Curious Myths of the Middle Ages, pp. 470 seq. (new ed., 1881); and J. C. Brunet, Manuel du libraire (vol. iii., 1862, s.v. Jean d’Arras).

MELVILLE, ANDREW (1545–1622), Scottish scholar, theologian and religious reformer, was the youngest son of Richard Melville (brother to Melville of Dysart), proprietor of Baldovry near Montrose, at which place Andrew was born on the 1st of August 1545. His father fell at the battle of Pinkie (1547), fighting in the van of the Scottish army, and, his wife having died soon after, the orphan was cared for by his eldest brother Richard (1522–1573). At an early age Melville began to show a taste for learning, and his brother did everything in his power to give him the best education. The rudiments of Latin he obtained at the grammar schools, after which he went to the university of St Andrews and learned how to use the Greek text of Aristotle, which no one else there understood. On completing his course, Melville left St Andrews with the reputation of "the best poet, philosopher, and Grecian of any young master in the land." He then, in 1564, being nineteen years of age, set out for France to perfect his education at the university of Paris. He there applied himself to Oriental languages, but also attended the last course of lectures delivered by Turnebus in the Greek chair, as well as those of Peter Ramus, whose philosophical method and plan of teaching he afterwards introduced into the universities of Scotland.

From Paris he proceeded to Poitiers (1566) to study civil law, and it was after his presentation to a munificently endowed mastership in the college of St Marceon that he entered the university of Leuven. As a resident of three years, however, political troubles compelled him to leave France, and he went to Geneva, where he was welcomed by Theodore Beza, at whose instigation he was appointed to the chair of humanity in the academy of Geneva. In addition to his teaching, however, he also applied himself to studies in Oriental literature, and in particular acquired from Cornelius Bertram, one of his brother professors, a knowledge of Syriac. While he resided at Geneva the massacre of St Bartholomew in 1572 drove an immense number of Protestant refugees to that city, including several of the most distinguished French men of letters of the time. Among these were several men learned in civil and political science, and their society increased Melville’s knowledge of the world and enlarged his ideas of civil and ecclesiastical liberty. In 1574 Melville returned to Scotland, and almost immediately received the appointment of principal of Glasgow University, which had fallen into an almost ruinous state, the college having been shut and the students dispersed. Melville,
MELVILLE, ARTHUR—MELVILLE, H.

However, set himself to establish a good educational system. He enlarged the curriculum at the college, and established chairs in languages, science, philosophy and divinity, which were confirmed by charter in 1577. His fame spread through the kingdom, and students flocked from all parts of Scotland and even beyond, till the class-rooms could not contain those who came for admission. He assisted in the reconstruction of Aberdeen University in 1573, and in order that he might do for St Andrews what he had done for Glasgow, he was appointed principal of St Mary's College, St Andrews, in 1580. His duties there comprehended the teaching, not only of theology, but of the Hebrew, Chaldee, Syriac and Rabbinical languages. The ability of his lectures was universally acknowledged, and he created a taste for the study of Greek literature. The reforms, however, which his new modes of teaching involved, and even some of his new doctrines, such as the non-infallibility of Aristotle, brought him into collision with other teachers in the university.

He was moderator of the General Assembly in 1582, and took part in the organization of the Church and the Presbyterian method. Troubles arose from the attempts of the court to force a system of Episcopacy upon the Church of Scotland (see SCOTLAND, CHURCH OF), and Melville prosecuted one of the "tulchan" bishops (Robert Montgomery, d. 1600). In consequence of this he was summoned before the Privy Council in February 1584, and had to flee into England in order to escape an absurd charge of treason which threatened imprisonment and not improbably his life. After an absence of twenty months he returned to Scotland in November 1585, and in March 1586 resumed his lectures in St Andrews, where he continued for twenty years; he became rector of the university in 1592. During the whole time he protected the liberties of the Scottish Church against all encroachments of the government. That in the main he and his coadjutors were fighting for the constitutionally guaranteed rights of the Church is admitted by all candid inquirers (see in particular J. R. S. Hict, from 1563, by S. B. Gardiner, vol. i. chap. ix.). The chief charge against Melville is that his fervour often led him to forget the reverence due to an "anointed monarch." Of this, however, it is not easy to judge. Manners at that time were rougher than at present. When the king acted in an arbitrary and illegal manner he needed the reminder that though he was king over men he was only "God's silly vassal." Melville's rudeness (if it is to be called so) was the outburst of just indignation from a man zealous for the purity of religion and regardless of consequences to himself. In 1599 he was deprived of the rectorship, but was made dean of the faculty of theology. The close of Melville's career in Scotland was at length brought about by James in characteristic fashion.

In 1606 Melville and seven other clergymen of the Church of Scotland were summoned to London in order "that his majesty might treat with them of such things as would tend to settle the peace of the Church." The contention of the whole of these faithful men was that the only way to accomplish that purpose was a free Assembly. Melville delivered his opinion to that effect in two long speeches with his accustomed freedom, and, having shortly afterwards written a sarcastic Latin epigram on some of the ritual practised in the chapel of Hampton Court, and some eavesdropper having conveyed the lines to the king, he was committed to the tower, and detained there for four years.

On regaining his liberty, and being refused permission to return to his own country, he was invited to fill a professor's chair in the university of Sedan, and there he spent the last eleven years of his life. He died at Sedan in 1622, at the age of seventy-seven.

See McCries, Andrew Melville (ed. 1819); Andrew Lang, History of Scotland (1902). (D. M.)

MELVILLE, ARTHUR (1838–1904), British painter, was born in Scotland, in a village of Haddingtonshire. He took up painting at an early age, and though he attended a night-school and studied afterwards in Paris and Grez, he learnt more from practice and personal observation than from school training. The remarkable colour-sense which is so notable a feature of his work, whether in oils or in water-colour, came to him during his travels in Persia, Egypt and India. Melville, though comparatively little known during his lifetime, was one of the most powerful influences in contemporary art, especially in his broad decorative treatment with water-colour. Though his vivid impressions of colour and movement are apparently recorded with feverish haste, they are the result of careful deliberation and selection. He was at his best in his water-colours of Eastern life and colour and his Venetian scenes, but he also painted several striking portraits in oils and a powerful colossal composition of "The Return from the Crucifixion" which remained unfinished at his death in 1904. At the Victoria and Albert Museum is one of his water-colours, "The Little Bull-Fight—Bravo, Toro!" and another, "An Oriental Goatherd," is in the Weimar Museum. But the majority of his pictures have been absorbed by private collectors.

A comprehensive memorial exhibition of Melville's works was held at the Royal Institute Galleries in London in 1906.

MELVILLE, HENRY DUNDAS, 1ST Viscount (1742–1821), British statesman, fourth son of Robert Dundas (1685–1753), lord president of the Scottish court of session, was born at Edinburgh in 1742, and was educated at the high school and university there. Becoming a member of the faculty of advocates in 1763, he soon acquired a leading position at the bar; and he had the advantage of the success of his half-brother Robert (1753–1802), who had become lord president of the court of session in 1760. He became solicitor-general to Scotland in 1766; but after his appointment as lord-advocate in 1775, he gradually relinquished his legal practice to devote his attention more exclusively to public business. In 1774 he was returned to parliament for Midlothian, and joined the party of Lord North; and notwithstanding his provincial dialect and ungraceful manner, he soon distinguished himself by his clear and argumentative speeches. After holding subordinate offices under the marquesses of Lorne and Pitt, he entered the cabinet in 1791 as home secretary. From 1794 to 1801 he was secretary at war under Pitt, who conceived for him a special friendship. In 1802 he was elevated to the peerage as Viscount Melville and Baron Dunira. Under Pitt in 1804 he again entered office as first lord of the admiralty, where he introduced numerous improvements in the details of the department. Suspicion had arisen, however, as to the financial management of the admiralty, of which Dundas had been treasurer between 1782 and 1800; in 1802 a commission of inquiry was appointed, which reported in 1805. The result was the impeachment of Lord Melville in 1806, on the initiative of Samuel Whitbread, for the misappropriation of public money; and though it ended in an acquittal, and nothing more than formal negligence lay against him, he never again held office. An earldom was offered in 1809 but declined; and he died on the 28th of May 1811.

His son Robert, 2nd Viscount Melville (1772–1851), filled various political offices and was first lord of the admiralty from 1812 to 1827 and from 1828 to 1830; his name is perpetuated by that of Melville Sound, because of his interest in Arctic exploration. His eldest son, HENRY DUNDAS, 3rd Viscount (1801–1876), a general in the army, played a distinguished part in the second Sikh War.

MELVILLE, HERMAN (1819–1891), American author, was born in New York City on the 1st of August 1819. He shipped as a cabin-boy at the age of eighteen, thus being enabled to make his first visit to England, and at twenty-two sailed for a long whaling cruise in the Pacific. After a year and a half he deserted his ship at the Marquesas Islands, on account of the cruelty of the captain; was captured by cannibals on the island of Nukahiva, and detained, without hardship, four months; was rescued by the crew of an Australian vessel, which he joined, and two years later reached New York. Thereafter, with the exception of a passenger voyage around the world in 1860, Melville resided in the United States, devoting himself to literature—though for a considerable period (1866–1883) he held a post in the New York custom-house—and being perhaps Hawthorne's most intimate
friend among the literary men of America. His writings are numerous, and of varying merit; his verse, patriotic and other, is forgotten; and his work of fiction and of travel are of irregular execution. Nevertheless, few authors have been enabled so freely to introduce romantic personal experiences into their books: in his first work, Types: A Peep at Polynesia Life, or Four Months’ Residence in a Valley of the Marquesas (1845), he described his escape from the cannibals; while in Omoo, a Narrative of Adventures in the South Seas (1847), White Jacket, or The World in a Man-of-War (1850), and especially Moby Dick, or The Whale (1851), he portrayed seafaring life and character with vigour and originality, and from a personal knowledge equal to that of Cooper, Marryat or Clark Russell. But these records of adventure were followed by other tales so turgid, eccentric, and opinionative, and loosely written as to seem the work of another author. Melville was the product of a period in American literature when the fiction written by writers below Irving, Poe and Hawthorne was measured by humble artistic standards. He died in New York on the 28th of September 1891.

MELVILLE, JAMES (1556-1614), Scottish reformer, nephew of Andrew Melville (q.v.), was born on the 26th of July 1556. He was educated at Montrose and St Leonard’s College, St Andrews. In 1574 he proceeded to the university of Glasgow, of which his uncle was principal. When his uncle was appointed, in 1580, principal of the New (later, St Mary’s) College, St Andrews, he was transferred to the chair of Oriental languages there. For three and a half years he lectured in the university, chiefly on Hebrew, but he had to flee to Berwick in May 1584 (a few months after his uncle’s exile) to escape the attacks of his ecclesiastical enemy, Bishop Adamson. After a short stay there and at Newcastle-on-Tyne, and again at Berwick, he proceeded to London, where he joined some of the leaders of the Scottish Presbyterian party. The taking of Stirling Castle in 1587 having changed the political and ecclesiastical positions in the north, he returned to Scotland in November of that year, and was restored to his office at St Andrews. From 1586 to his death he took an active part in Church controversy. In 1588 he was moderator of the General Assembly and on several occasions represented his party in conferences with the court. Despite his antagonism to James’s ecclesiastical schemes, he appears to have won the king’s respect. He answered, with his uncle, a royal summons to London in 1606, and on the restoration of the Church policy the uncompromising attitude of the kinsmen, though it was made the excuse for sending the elder to the Tower, brought no further punishment to James than easy detention within ten miles of Newcastle-on-Tyne. During his residence there it was made clear to him by the king’s agents that he would receive high reward if he supported the royal plans. In 1613 negotiations were begun for his return to Scotland, but his health was broken, and he died at Berwick in January 1614.

Melville has left ample materials for the history of his time from the Presbyterian standpoint, in (a) correspondence with his uncle Andrew Melville (MS. in the library of the university of Edinburgh), and (b) the Ane Boock of the Life of the late Andrew Melville, the latter is written in a vigorous, fresh style, and is especially direct in its descriptions of contemporaries. His sketch of John Knox at St Andrews is one of his best passages.

As a writer of verse he compared favourably with his uncle. All his pieces, with the exception of a “libellus supplex” to King James, are written in Scots. He translated a portion of the Zodiacus regum of Palingenius, and adapted some passages from Scaliger under the title of Description of the Spanish parts naturall. His Spiritual Propinnoe of a Pastour to his People (1598), The Blacke Bastill, a lamentation for the kirk (1611), Three may keep Counsell, give Twa be away, The Belief of the Singing Soul, David’s Tragic Poem, and a number of Sonnets show no originality and indifferent technical ability.

The Diary was printed by the Bannatyne Club in 1829, and by the Wodrow Society in 1842. Large portions of it are incorporated in David Calderwood’s (1572-1580) History of the Kirk of Scotland (first printed in 1678). For the life and times, see Thomas M’Crie’s Life of Andrew Melville.

MELVILLE, SIR JAMES (1555-1617), Scottish diplomatist and memoir writer, was the third son of Sir John Melville, laird of Raith in the county of Fife, who was executed for treason in 1548. One of his brothers was Robert, 1st Baron Melville of Monimail (1527-1621). James Melville in 1549 went to France to introduce the page to Mary Queen of Scots. Serving on the French side at the battle of St Quentin in 1557 Melville was wounded and taken prisoner. He subsequently carried out a number of diplomatic missions for Henry II. of France. On Mary’s return to Scotland in 1561 she gave Melville a pension and an appointment in her household, and she employed him as special emissary to reconcile Queen Elizabeth to her marriage with Darnley. After the murder of Darnley in February 1567, Melville joined Lord Herries in boldly warning Mary of the danger and disgrace of her projected marriage with Bothwell, and was only saved from the latter’s vengeance in consequence by the courageous resolution of the queen. During the troubled times following Mary’s imprisonment and abduction Melville conducted several diplomatic missions of importance, and won the confidence of James VI. when the king took the government into his own hands. Having been adopted as his heir by the reformer Henry Balnaves, he inherited from him, at his death in 1579, the estate of Halhill in Fife; and he retired thither in 1603, refusing the request of James to accompany him to London on his accession to the English throne. At Halhill Melville wrote the Memoirs of my Own Life, a valuable authority for the history of these latest public services of his. He died there in 1617.

Sir James Melville died at Halhill on the 17th of November 1617. By his wife, Christina Boswell, he had one son and two daughters; the eldest of these, Elizabeth, who married John Colville, de jure 3rd Baron Colville of Culross, has been identified with the author of a poem published in 1603, entitled Ane Godlie Stricht.

See the Memoirs mentioned above, of which the most modern edition is that prepared by T. Thompson for the Bannatyne Club (Edinburgh, 1827).

MELVILL VAN CARNabee, Pister, Baron (1816-1856), Dutch geographer, was born at the Hague on the 20th of May 1816. He traced his descent from an old Scottish family, originally, it is said, of Hungarian extraction. Destined for the navy, in which his grandfather Pieter Melvill van Carnbee (1743-1810) had been admiral, he imbibed a taste for hydrography and cartography as a student in the college of Medemblik, and he showed his capacity as a surveyor on his first voyage to the Dutch Indies (1835). In 1839 he was again in the East, and was attached to the hydrographical bureau at Batavia. While the important hydrographic work collected by the old East India Company, he completed a map of Java in five sheets, accompanied by sailing directions (Amsterdam, 1842). He remained in the East till 1845 collecting materials for a chart of the waters between Sumatra and Borneo (two sheets, 1845 and 1846). On his return to Holland he was attached to the naval department with the charge of studying the history of the hydrography of the Dutch East Indies. He also undertook, in connexion with P. F. von Siebold, the publication of the Moniteur des Indes, a valuable series of scientific papers, mainly from his own pen, on the foreign possessions of Holland, which was continued for three years. In 1850 Melvill returned to India as lieutenant of the first class and adjutant to Vice-Admiral van den Bosch; and after the premature death of this commander he was again appointed keeper of the charts at Batavia. In 1853 he obtained exemption from active naval service that he might devote himself to a general atlas of the Dutch Indies. But in 1856 he fell a victim to climate, dying at Batavia on the 24th of October. In spite of delays in engraving, twenty-five sheets of the atlas were already finished, but it was not till 1862 that the whole work, which was done by Peritricha, was completed by Lieut.-Colonel W. F. Versteeg. In 1843 Melvill received the decoration of the Netherlands Lion, in 1849 that of the Legion of Honour.

MEMBRANELLE, an organ in Ciliate Infusoria (q.v.), a flattened assemblage of adherent cilia, like the plates of Ctenophora (q.v.): such are arranged in a series in the adoral wreath of the Heterothricidae Oligotrichidae and Hypotrichidae and constitute the posterior girdle of Peritrichia.
MEMEL—or MIEMEN.

MEMEL, or NIELEN, a river of Russia and Prussia, rising in the middle of the Russian government of Minsk at an altitude of 580 ft. and flowing generally west as far as Gродно. Thence it runs north to Kovno, separating Poland from Russia, and at Kovno it turns west again, still dividing Poland from Russia, until it enters the Prussian province of East Prussia, through which it flows west and north-west past Tilsit for a distance of 70 m. and finally enters the Kurfürstes Haff by several arms. Of these, those principally used for navigation are the Russ, and its chief branch the Atmat. The Russ is connected with the outlet of the Kurfürstes Haff at Memel by a canal, while another canal links the Gilge arm southward with the Pregel. Considerable quantities of timber are floated down the Memel, and large amounts of corn shipped down it and its navigable tributary the Viliya. The lowlands of Tilsit are protected against inundation by dikes. Total length of the river, 490 m.; area of its basin, 34,950 sq. m. It is navigable for large vessels as far as Gродно.

See H. Keller, Memel, Pregel and Weichselstrom (2 vols., Berlin, 1900); and Schickert, Wasserwege und Deichweisen in der Memelnierung (Königsberg, 1901).

MEMLING, HANS. (c. 1430-1494), Flemish painter, whose art gave lustre to Bruges in the period of its political and commercial decline. Though much has been written respecting the rise and fall of the school which made this city famous, it remains a moot question whether that school ever truly existed. Like Rome or Naples, Bruges absorbed the talents which were formed and developed in humbler centres. Jan Van Eyck first gained repute at Obert and the Hague before he acquired a domicile elsewhere, and Memling, who have reason to think, was a skilled and bountiful artist at Bruges. The annals of the city are silent as to the birth and education of a painter whose name was inaccurately spelt by different authors, and whose identity was lost under the various appellations of Hans and Haussaer, or Hemling, Memling, and Memlinc. But W. H. J. Weale mentions a contemporary document discovered in 1889, according to which Memlinc “drew his origin from the ecclesiastical principality of Mayence,” and died at Bruges on the 11th of August 1494. He probably served his apprenticeship at Mayence or Cologne, and later worked under Rogier van der Weyden. He did not come to Bruges until about 1467, and certainly not as a wounded fugitive from the field of Nancy. The story is fiction, as is also the report that he was sheltered and cured by the Hospitals at Bruges, and, to show his gratitude, refused payment for a picture he had painted. Memlinc did indeed paint for the Hospitals, but he painted not one but many pictures, and he did so in 1479 and 1480, being probably known to his patrons of St John by many masterpieces even before the battle of Nancy.

Memlinc is only connected with military operations in a mediate and distant sense. His name appears on a list of subscribers to the loan which was raised by Maximilian of Austria to push hostilities against France in the year 1480. In 1477, when he is falsely said to have fallen, and when Charles the Bold was killed, he was under contract to furnish an altarpiece for the gild-chapel of the booksellers of Bruges; and this altarpiece, now preserved, under the name of the “Seven Griefs of Mary,” in the gallery of Turin, is one of the fine creations of his riper age, and not inferior in any way to those of 1479 in the hospital of St John, which for their part are hardly less interesting as illustrative of the master’s power than the “Last Judgment” in the cathedral of Danzig. Critical opinion has been unanimous in assigning the altarpiece of Danzig to Memlinc; and by this it affirms that Memlinc was a resident and skilled artist at Bruges in 1473; for in this year the so-called “Last Judgment” was painted and sold to a merchant at Bruges, who shipped it there on board of a vessel bound to the Mediterranean, which was captured by a Danzig privateer in that very year. But, in order that Memlinc’s repute should be so far as to make his pictures purchasable, as this had been, by an agent of the Medici at Bruges, it is incumbent on us to acknowledge that he had furnished sufficient proofs before that time of the skill which excited the wonder of such highly cultivated patrons.

It is characteristic that the oldest allusions to pictures connected with Memlinc’s name are those which point to relations with the Burgundian court. The inventories of Margaret of Austria, drawn up in 1524, allude to a tripich of the “God of Pity” by Rogier van der Weyden, of which the wings containing angels were by “Master Hans.” But this entry is less important as affording testimony in favour of the preservation of Memlinc’s work than as showing his connexion with an older Flemish craftsman. For ages Rogier van der Weyden was acknowledged as an artist of the school of Bruges, until records of undisputed authenticity demonstrated that he was bred at Tournai and settled at Brussels. Nothing seems more natural than the conjuncture of his name with that of Memlinc as the author of an altarpiece, since, though Memlinc’s youth remains obscure, it is clear from the style of his manhood that he was taught in the painting-room of Van der Weyden. Nor is it beyond the limits of probability that it was Van der Weyden who received commissions at a distance from Brussels, and first took his pupil to Bruges, where he afterwards dwelt. The clearest evidence of the connexion of the two masters is that afforded by pictures, particularly an altarpiece, which has alternately been assigned to each of them, and which may possibly be due to their joint labours. In this altarpiece, which is a triptych ordered for a patron of the house of Sforza, we find the style of Van der Weyden in the central panel of the Crucifixion, and that of Memlinc in the episodes on the wings. Yet the whole piece was assigned to the former in the Zambecchiare collection at Bruges, whilst the latter was allotted to the latter in the Middleton sale in London in 1875. At first we may think, a closer resemblance might be traced between the two artists than that disclosed in later works of Memlinc, but the delicate organization of the younger painter, perhaps also a milder appreciation of the duties of a Christian artist, may have led Memlinc to realise a sweet and perfect ideal, without losing, on that account, the feeling of his master. He certainly exchanged the asceticism of Van der Weyden for a sentiment of less energetic concentration. He softened his teacher’s asperities and bitter hardness of expression.

In the oldest form in which Memlinc’s style is displayed, or rather in that example which represents the Baptist in the gallery of Munich, we are supposed to contemplate an effort of the year 1470. The finish of this piece is scarcely surpassed, though the subject is more important, by that of the “Last Judgment” of Danzig.
MEMMINGEN—MEMNON

But the latter is more interesting than the former, because it tells how Memline, long after Rogier's death and his own settlement at Bruges, preserved the traditions of sacred art which had been applied in the first part of the century by Rogier van der Weyden to the Memminger chapel in the cathedral of Memmingen. We may advance a supposition that he purged his master's manner of excessive stringency, and added to his other qualities a velvet softness of pigment, a delicate transparence of colours, and yielding grace of slender forms. That such a beautiful workmanship might be found in the hands of a painter for the Italian market is not surprising when we recollect that picture-fanciers in those country were familiar with the beauties of Memline's compositions, as shown in the preference given to them by such men as Cardinal Bembo of Venice, and the heads of the house of Medici at Florence. But Memline's reputation was not confined to Italy or Flanders. The "Madonna and Saints" which passed out of the Duchatel collection into the hands of Sir John Chevallier, and then to Sir John Donne and now to Chatsworth, and other noble specimens in English and Continental private houses, show that his work was as widely known and appreciated as it is in the state of civilization in which it was produced. It was perhaps not the sole attraction that they gave the most tender and delicate possible impersonations of the "Mother of Christ" that could suit the taste of that age in any European country. But the portraits of the donors, which, of course, were executed in 1480. The delicacy of finish in its miniature figures, the variety of its landscapes and costume, the marvellous patience with which its details are given, are all matters of enjoyment to the spectator. There is later work of Memline, and of Master of St Ursula in the academy, or the Newenhuben "Madonna" in the hospital of Bruges, or a large "Crucifixion," with scenes from the Passion, of 1491 in the cathedral of Liége. But as we near the close of Memline's life we find in his Altarpiece at Bruges, the marriage of Joachim and Anne, which the whole church concurred in with the Passion, that he could work more alone; and, as usual in such cases, the labour of disciples is substituted for his own. The registers of the painters' corporation at Bruges give the names of two apprentices, who served the master, and paid dues as the guild in 1480 and 1486. These subordinate names remained obscure.

The trustees of his will appeared before the court of wards at Bruges on the 10th of December 1495, and we gather from records of that date and place that Memline left behind several children and a considerable property.

**MEMMENGE,** a town of Germany, in the kingdom of Bavaria, on the Ach, a tributary of the Iller, 35 m. S.W. of Augsburg on the railway to Ulm. Pop. (1905), 61,618. It is partly surrounded with walls, and has some interesting old gates and houses. It contains the fine Gothic church of St Martin, which contains 67 beautifully carved choir-stalls, and a town hall dating from about 1580. Its industrial products are yarn, calico, woollen goods, thread. A considerable trade is carried on in hops, which are extensively cultivated in the neighbourhood, and in cattle, wool, leather and grain.

Memmingen, first mentioned in a document of 1016, belonged originally to the Guelph family, and later to the Hohenstaufen. In 1286 it became a free city of the empire, a position which it main-

tained down to 1802, when it was allotted to Bavaria. In 1331 it was a member of the league of Swiban towns; in 1530 it was one of the four towns which presented the Confraternity of the Black Madonna to the emperor Ferdinand I.; and a few years later it joined the league of German Catholic States. It was contested between the Swedes and the Imperialists. In May 1800 the French gained a victory over the Austrians near Memmingen.

See Dobel, Memmings im Reformationszeitalter (Augsburg, 1819); and Claus, Memmings Chronik, 1826—1892 (Memmingen, 1894).

**MEMMIUS, GAUSS** (incorrectly called Gemellus, "The Twin"), Roman orator and poet, tribune of the people (66 B.C.), friend of Lucretius and Catullus. At first a strong supporter of Pompey, he quarrelled with him, and went over to Caesar, whom he had previously attacked. In 54, as candidate for the consulship, he lost Caesar's support by revealing a scandalous transaction in which he and his fellow candidate had been implicated ( Cic. Ad Att. iv. 15—18). Being subsequently condemned for illegal practices at the election, he withdrew to Athens, and afterwards to Mytilene. He died about 49 B.C. He is remembered chiefly because it was to him that Lucretius addressed the De rerum natura, perhaps with the idea of making him a convert to the doctrines of Epicurus. He appears from Cicero (Ad Fam. xiii. 1) that he possessed an estate on which were the ruins of an ancient temple. He probably spent much of his time in looking at it from a house for himself. According to Ovid (Trist. ii. 433) he was the author of erotic poems. He possessed considerable oratorical abilities, but his contempt for Latin letters and preference for Greek models impaired his efficiency as an advocate (Cic. Brut. 70).

Another GAIUS MEMMIUS, tribune in 111 B.C., attacked the aristocrats on a charge of corrupt relations with Jugurtha. Memmius subsequently stood for the consulship in 99, but was slain in a riot stirred up by his rival the praetor Galba. Sallust describes him as an orator, but Cicero (De oratore, i. 59, 70) had a poor opinion of him.

**MEMNON,** in Greek mythology, son of Tithonus and Eos (Dawn), king of the Aethiopians. Although mentioned in Hesiod and the Odyssey, he is rather a post-Homeric hero. After the death of Hector he went to assist his uncle Priam against the Greeks. He performed prodigies of valour, but was slain by Achilles, after he had himself killed Antilochus, the son of Nestor and the friend of Achilles. His mother, Eos, removed his body from the field of battle, and it was said that Zeus, moved by her tears, bestowed immortality upon him. According to another account, Memnon was engaged in single combat with Ajax Telemonius, when Achilles slew him before his warriors had time to come to his aid (Dictys Cretensis iv. 6; Quintus Smyrnaeus ii.; Pindar, Pythia, vi. 31). His mother wept for him every morning, and the early dew-drops were said to be his tears. His companions were changed into birds, called Memnonides, which came every year to fight and lament over his grave, which was variously located (Ovid, Metam. xiii. 376—622; Pausanias x. 31). The story of Memnon was the subject of the lost Aethiopis of Arctinus of Miletus; the chief source from which our knowledge of him is derived is the second book of the Posthemeria of Quintus Smyrnaeus (itself probably an adaptation of the works of Arctinus and Lesches), where his exploits and death are described at length. As an Aethiopian, Memnon was described as black, but was noted for his beauty. The fight between Achilles and Memnon was often represented by Greek artists, as on the chest of Cypselus, and more than one Greek play was written bearing his name as a title. In later times the tendency was to regard Memnon as a real historical figure. He was said to have built the royal citadel of Susa, called after him the Memnonion, and to have been sent by Teutamis, king of Assyria, to the assistance of his vassal Priam (Diod. Sic. ii. 22). In Egypt, the name of Memnon was connected with the colossal statues of Amenophis (Amenhotep) III. A number of these, two of which still remain, was probably partly destroyed by an earthquake (27 B.C.) and the upper part thrown down. A curious phenomenon then occurred. Every morning, when the rays of the rising sun touched the statue, it gave forth musical sounds, like the
MEMNON OF RHODES—MEMPHIS

moaning noise or the sharp twang of a harp-string. This was supposed to be the voice of Memnon responding to the greeting of his mother Eos. After the restoration of the statue by Septimius Severus (A.D. 170) the sounds ceased. The sound, which has been heard by modern travellers, is generally attributed to the passage of the air through the pores of the stone, chiefly due to the change of temperature at sunrise. Others have held that it was a device of the priests. Strabo (xvii. 816), the first to mention the sound, declares that he himself heard it, and Pausanias (i. 42, 3) says “one would compare the sound most nearly to the broken chord of a harp or a lute” (Juvenal xv. 5, with Mayor’s note; Tacitus, Annals, i. 61).

The supporters of the solar theory look upon Memnon as the son of the dawn, who, though he might vanish from sight for a time, could not be destroyed; hence the immortality bestowed upon him by Zeus. He comes from the east, that is, the land of the rising sun. On early Greek vases he is represented as borne through the air; this is the sun making his way to his place of departure in the west. Both Susa and Egyptian Thebes, where there was a Memnon or temple in honour of the hero, were centres of sun-worship. “Eos, the mother of Memnon, has transparently asserted that her child must rise again as surely as the sun reappears to run his daily course across the heavens” (G. W. Cox, Mythology and Folklore, p. 247).[1]

See Carbone, Le Statuette de Memnon (1833); C. R. Lepsius, Briefe aus Ägypten (1852); “The Voice of Memnon” in Edinburgh Review (July 1886); article by R. Holland in Roscher’s Lexikon der Mythologie.

MEMNON OF RHODES, brother of Mentor (q.v.), with whom he entered the services of the rebellious satrap Artabazus of Phrygia, who married his sister. Mentor after the conquest of Egypt rose high in the favour of the king, and Memnon, who had taken refuge with Artabazus at the Macedonian court, became a zealous adherent of the Persian king; he assisted Mentor in subduing the rebellious satraps and dynasts in Asia Minor, and succeeded him as general of the Persian troops.

In the pseudo-Aristotelian Oeconomicus, ii. 28, stories are told of his methods of obtaining money and evading his obligations; thus he extorted a large sum of money from the conquered inhabitants of Lampsacus and cheated his soldiers out of a part of their pay. He entered a large territory east of Troy (Arrian i. 17, 8; Strabo xiii. 587). He gained some successes against the Philip II. of Macedon in 336 (Diod. xvii. 6; Polyena. v. 44, 4, 5) and commanded the Persian army against Alexander’s invasion. Convinced that it was impossible to meet Alexander in a pitched battle, his plan was to lay waste the country, and retire into the interior, meanwhile organizing resistance on sea (where the Persians were far superior to the Macedonians) and carrying the war into Greece. But his advice was overruled by the Persian satraps, who forced him to fight at the Granicus. After his defeat he tried to organize the maritime war and occupied the Greek islands, but in the beginning of 333 he fell ill and died (Arrian ii. i, 1).

MEMORANDUM OF ASSOCIATION, in English company law, a document subscribed to by seven or more persons associated for any lawful purpose, by subscribing to which, and otherwise complying with the requisitions of the Companies Acts in respect of registration, they may form themselves into an incorporated company by limited liability (see Company).

MEMORIAL DAY (or DECORATION DAY), a holiday observed in the northern states of the United States on the 30th of May, in honour of soldiers killed in the American Civil War, and especially for the decoration of their graves with flags and flowers. Before the close of the Civil War the 30th of May was thus celebrated in several of the southern states; in the North there was no fixed day commonly celebrated until 1868, when (on the 5th of May) Commander-in-Chief John A. Logan, of the Grand Army of the Republic, issued a general order designating the 30th of May 1868 “for the purpose of strewing with flowers or otherwise decorating the graves of comrades who died in defense of their country during the late rebellion”; Logan did this “with the hope that it will be kept up from year to year.” In 1883 the Grand Army urged that the “proper designation of May 30 is Memorial Day”—not Decoration Day. Rhode Island

made it a legal holiday in 1874, Vermont in 1876, and New Hampshire in 1877; and by 1910 it was a legal holiday in all the states and territories save Alabama, Alaska, Arkansas, Florida, Georgia, Louisiana, Mississippi, North Carolina, South Carolina and Texas. In Virginia the 30th of May is observed as a Confederate Memorial Day. The 3rd of June (the birthday of Jefferson Davis) is observed as Confederate Memorial Day in Louisiana and Tennessee; the 26th of April in Alabama, Florida, Georgia and Mississippi; and the 10th of May in North Carolina and South Carolina.

MEMPHIS, the capital of Egypt through most of its early history, now represented by the rubbish mounds at Bedreshên on the W. bank of the Nile 14 m. S. of Cairo. As the chief seat of the worship of Ptah, the artisan god (Hephaestus), Memphis must have existed from a very remote time. But its greatness probably began with Menes (q.v.), who united the kingdoms of Upper and Lower Egypt, and is said to have secured the site for his capital near the border of the two lands by diverting the course of the river eastward. Memphis was the chief city of the 3rd nome of Lower Egypt; in its early days it was known as “the white walls” or the “white wall,” a name which clung to it till the 12th dynasty. The residence here of Pepi I of the VIth Dynasty, as his sarcophagus in the necropolis, was named Mn-nfr, and this gradually became the usual designation of the whole city, becoming Menni, Membí in late Egyptian, i.e. Memphis. It was also called Hakeptah, “Residence of the ka of Ptah,” and this name furnishes a possible origin for that of Egypt (Abydos). Various dynasties had their ancestral seats elsewhere and individual kings built their palaces and pyramids at some distance up or down the valley, but Memphis must have been generally the centre of the government and the largest city in Egypt until the New Empire (Dyns. XVIII.–XX.), when Thebes took the lead. In the succeeding period it regained its ancient position. The government of the Persian satrap was seated in Memphis. After the conquest of Alexander the city quickly lost its supremacy to his new foundation, and although it remained the greatest native centre, its population was less than that of Alexandria. In the time of Strabo (xvii. 807) it was the second city of Egypt, inferior only to Alexandria, and with a mixed population like the latter.

In the time of Strabo (xvii. 807) it was the second city of Egypt, inferior only to Alexandria, and with a mixed population like the latter.

A Byblos mastaba-tombs, described by Maspero, was cut into the bedrock. One of them was described by Maspero as the Serapeum or sepulchre of the Apis bulls, discovered by Mariette in 1851. From 1902 J. E. Quibell was charged by the Service des Antiquités solely with the excavations in this vast necropolis. His principal discovery has been the extensive remains of the Coptic monastery of St Jeremias, with remarkable sculptures and frescoes. Flinders Petrie began the systematic exploration of the ruins of Bedreshên, and in three seasons cleared up much of the topography of the ancient city, identifying the mound of the citadel and palace, a foreign quarter, &c. Among his finds not the least interesting is a large series of terra-cotta heads representing the characteristic features of the foreigners who thronged the bazaars of Memphis. They date from the Persian rule down to
the Ptolemaic period and are evidently modelled by Greek workmen. In the Old Testament Memphis is mentioned under the names of Moph (Hez. ix. 6) and Noph (Isa. xix. 13; Jer. ii. 16; Ezek. xxx. 14, 16).

**MEMPHIS.** a port of entry and the largest city of Tennessee, U.S.A., and the county-seat of Shelby county, on the Mississippi river, in the S.W. corner of the state. Pop. (1860), 22,623; (1870), 40,226; (1880), 33,592; (1890), 44,945; (1900), 102,320, of whom 5110 were foreign-born and 49,010 were negroes; (1910) 131,105. It is served by the Chicago, Rock Island & Pacific, the St Louis & San Francisco, the Illinois Central, the Southern, the Louisville & Nashville, the Nashville, Chattanooga & St Louis, the St Louis South-Western, the St Louis, Iron Mountain & Southern and the Yazoo & Mississippi Valley railways, and by steamboats on the Mississippi. The river is spanned here by a cantilever railway bridge 1895 ft. long, completed in 1892. The city is flanked on the north by the Chickasaw Bluffs, more than 40 ft. above high water; the streets are broad, well paved and pleasantly shaded; and a broad levee overlooks the river. In Court Square, in the heart of the city, are many fine old trees and a bust of President Andrew Jackson. In 1909 the city had about 1000 acres of parks and 11½ m. of parkways, besides two race-courses. Overton Park has beautiful playgrounds and a great zoological collection. Five miles from Memphis is a National Cemetery. Among the prominent buildings are the United States Government building, the county Court house, Cotton Exchange, Business Men's Club, Goodwyn Institute, containing an auditorium and the public library, the Cossett Free Library, Grand Opera House, Lyceum Theatre, Auditorium, Gayoso Hotel, Memphis Evening Scimitar building, the Union and Planters' Bank and Trust Company building, Equitable building, Memphis Trust building, Tennessee Trust building, the Bank of Commerce, Woman's building (containing offices for business women), Masonic Temple, Odd Fellows' building and the Commercial Appeal building. Among educational institutions are the College of Christian Brothers (Roman Catholic, opened in 1871), Memphis Hospital Medical College, College of Physicians and Surgeons, Hannibal Medical College for negroes and Le Moyne Normal Institute, also for negroes. Memphis is the see of a Protestant Episcopal bishopric. The city is supplied with water from more than eighty artesian wells, having an average depth of about 400 ft.

Owing to its situation at the head of deep water navigation on the Mississippi, Memphis has become a leading commercial city of the southern states; its trade in cotton, lumber, groceries, mules and horses is especially large. The city also manufactures large quantities of cotton-seed oil and cake, lumber, flour and grit-mill products, foundry and machine-shop manufactures, confectionery, carriages and wagons, paints, furniture, bricks, cigar-ware, and the manufactures of St Louis & San Francisco railways have workshops here. The total value of the city's manufactures increased from $13,344,538 in 1880 to $17,923,959 ($14,233,483 being factory product) in 1900, and to $21,416,817 (factory product) in 1905, an increase of 40% over the value of the factory product in 1900.

Chickasaw Bluffs were named from the Chickasaw Indians, who were in possession when white men first came to the vicinity. Late in the 17th century the French built a fort on the site of Memphis, and during most of the 18th century this site was held either by the French or the Spanish. In 1797 it passed into the possession of the United States. By a treaty of the 10th of October 1818, negotiated by General Andrew Jackson and General Isaac Shelby, the Chickasaws ceded all their claims east of the Mississippi, and early in 1819 Memphis was laid out in accordance with an agreement entered into by John Overton (1766-1833), Andrew Jackson and James Winchester (1752-1826), the proprietors of the land. Its name was suggested from the similarity of its situation on the Mississippi to that of the Egyptian city on the Nile. Memphis was incorporated as a town in 1827, and in 1849 was chartered as a city. Near Memphis, on the 6th of June 1862, a Union fleet of 9 vessels and 68 guns, under Commander Charles Henry Davis (1807-77), defeated a Confederate fleet of 8 vessels and 28 guns under Commander J. E. Montgomery after a contest of little more than one hour, three of the Confederate vessels being destroyed and four of them captured, and from this victory until the close of the war the city was in possession of the Union forces. In August 1864, however, a Confederate force under General N. B. Forrest raided it and captured several hundred prisoners. The decrease of population between 1870 and 1880 was due to the ravages of yellow fever in 1873, 1878 and 1879. The epidemic of 1873 resulted in over two thousand deaths, and that of 1878 in a total of 5150, of whom 4250 were whites and 900 negroes. At the return of the fever in 1879 better care and strict quarantine arrangements prevailed, but there were 497 deaths. During the epidemics of 1878 and 1879 fully two-thirds of the population fled from the city, many of whom died of the fever at other places, and a still larger number did not return. For three months during each year business was suspended, and all ingress or egress except for the most necessary purposes was forbidden.

The city was left almost bankrupt, and as a means of relief the legislature of the state in January 1879 repealed the city's charter, and, assuming exclusive control of its taxation and finances, constituted it simply a "taxing district," placing its government in the hands of a "legislative council." This anomalous proceeding was declared unconstitutional by the supreme court of Tennessee. Subsequently the streets were cleansed and repaved, an improved sewer system was put in operation, and the water supply was obtained from artesian wells. In 1891 a new city charter was obtained, and in 1907 the "Huston plan" (see Houston, Texas) was adopted for Memphis by the state legislature. The act, however, was declared unconstitutional by the state supreme court, on the ground that it would force elected officers out of office before the expiration of their constitutional terms; and in 1910 a new charter on the Houston plan was adopted by the legislature, to become effective on the 1st of January 1910, providing for a government by five commissioners, each having charge of a separate department.

**MENA, JUAN DE** (1411-1456), Spanish poet, was born at Córdova in 1411. In his twenty-fourth year he matriculated at the university of Salamanca, and studied later at Rome. His scholarship obtained for him the post of Latin secretary at the court of Castile; subsequently he became historiographer to John II. and magistrate at Córdova. According to the *Epíclo* of Valerio Francisco Romero, Mená died from natural causes in 1456; popular tradition, however, ascribes his death to a fall from his mule. Though nominally the king's chronicler, Mená had no share in the *Crónica de Don Juan II. o la Cumbre de sus Reinas*; the *Crónica de Don Juan II.* was written by the historian Fray Juan de la Cueva; but three authentic specimens of his cumbersome prose exist in the commentary to his ballad poem *La Coronación o Calamocito*, in the *Hidalgía en romance* (an abridged version of Homer), and in the unpublished *Memorias de algunos linajes antiguas e nobles de Castilla*. He is conjectured to be the author of the satirical *Coplas de la panadería*; but, apart from the fact that these verses are ascribed by Argote de Molina to Iñigo Ortiz de Zúñiga, they are instinct with a tart humour of which Mená was destitute. His principal work is his allegorical poem, *El Laberinto de Fortuna*, dedicated to John II.; in the oldest manuscripts it consists of 297 stanzas, but three more stanzas were added to it later, and hence the alternative, popular title of *Las Trasienas*. The *Laberinto* is modelled on Dante, and further contains reminiscences of the *Roman de la rose*, as well as episodes borrowed from Virgil and Lucan. It is marred by excessive emphasis and pedantic diction, and the *arte mayor* measure in which it is written is monotonous; but many octaves are of such excellence that the *arte mayor* metre continued in fashion for nearly a
MENA, PEDRO DE—MENAHEM

century. The poem, as a whole, is tedious; yet its dignified expression of patriotic spirit has won the admiration of Spaniards from Cervantes' time to our own.

A critical edition of the Laberinto has been issued by R. Foulché-Delbosc (Mâcon, 1904).

MENA, PEDRO DE (d. 1693), Spanish sculptor, was born in Adra. He was a pupil of his father as well as of Alonzo Cano. His first conspicuous success was achieved in work for the convent El Angel at Granada, including figures of St Joseph, St Antony of Padua, St Diego, St Pedro Meñatara, St Francis and Santa Clara. In 1658 he signed a contract for sculptural work on the choir stalls of the cathedral at Malaga—this work extending over four years. Other works are, statues of the Madonna and child and of St Joseph in Madrid, the polychromatic figures in the church of St Isidoro, the Magdalena and the Gertrudis in the church of St Martin (Madrid), the crucifixion in the Nuestra Señora de Gracia (Madrid), the statue of St Francis of Assisi in Toledo, and of St Joseph in the St Nicholas church in Murcia. Between 1673 and 1679 Mena worked at Cordova. About 1680 he was in Granada, where he executed a half-length Madonna and child (seated) for St Dominicos. Mena died in Malaga in 1693. He and Mora (q.v.) may be regarded as artistic descendants of Montañez and Alonzo Cano, but in technical skill and the expression of religious motive his statues are unsurpassed in the sculpture of Spain. His feeling for the nude was remarkable. Like his immediate predecessors he excelled in the portrayal of contemplative figures and scenes; Mena's drawing of Santiago leaping upon his charger is good, and the carving admirable, but the necessary movement for so spirited an action is lacking.

See B. Haendcke, Studien zur Geschichte der spanischen Plastik (Strassburg, 1900).

MENABREA, LUIGI FEDERICO, Marquis of Valdora (1809–1869), Italian general and statesman, was born at Chambéry on the 4th of September 1809. He was educated at the university of Turin, where he qualified as an engineer and became a doctor of mathematics. As an officer of engineers he replaced Cavour in 1831 at the fortress of Bardo. He then became professor of mechanics and construction at the military academy and at the university of Turin. King Charles Albert sent him in 1848 on diplomatic missions to secure the adhesion of Modena and Parma to Sardinia. He entered the Piedmontese parliament, and was attached successively to the Ministries of War and Foreign Affairs. He belonged to the right centre, and until the events of 1859 he believed in the possibility of a compromise between the Vatican and the state. He was major-general and commander-in-chief of the engineers in the Lombard campaign of 1859. He superintended the siege works against Peschiera, was present at Palestro and Solferino, and repaired the fortifications of some of the northern fortresses. In 1860 he became lieutenant-general and conducted the siege of Gaeta. He was appointed senator and received the title of count. Entering the Ricassi cabinet of 1861 as minister of marine, he held the portfolio of public works in the first cabinet of Farini and Mignetti cabinets. After the war of 1866 he was chosen as Italian plenipotentiary for the negotiation of the treaty of Prague and for the transfer of Venetia to Italy. In October 1867 he succeeded Rattazzi in the premiership, and was called upon to deal with the difficult situation created by Garibaldi's invasion of the Papal States and by the catastrophe of Mentana. Menabrea disavowed Garibaldi and instituted judicial proceedings against him; but in negotiations with the French government he contested against the retention of the temporal power by the pope and insisted on the Italian right of interference in Rome. He was in the secret of the direct negotiations between Victor Emanuel and Napoleon III. In June 1869, and refused to entertain the idea of a French alliance unless Italy were allowed to occupy the Papal States, and, on occasion, Rome itself. On the eve of the assembly of the Oecumenical Council at Rome Menabrea reserved to the Italian government its right in respect of any measures directed against Italian institutions. He withdrew from seminary students in 1869 the exemption from military service which they hitherto enjoyed. Throughout his term of office he was supported by the finance minister Count Cambray Digny, who forced through parliament the grant tax proposed by Quintino Sella, though in an altered form from the earlier proposal. After a series of changes in the cabinet, and many crises, Menabrea resigned in December 1869 on the election of a new chamber in which he did not command a majority. He was made marquis of Valdora in 1875. His successor in the premiership, Giovanni Lanza, in order to remove him from his influential position as aide-de-camp to the king, sent him to London as ambassador, where he remained until in 1882 he replaced General Gialdini at the Paris Embassy. Ten years later he withdrew from public life, and died at Saint Capin on the 24th of May 1896.

MÉNAGE, GILLES (1613–1692), French scholar, son of Guillaume Ménage, king's advocate at Angers, was born in that city on the 15th of August 1613. A tenacious memory and an early enthusiasm for learning carried him speedily through his literary and professional studies, and he practised at the bar at Angers as early as 1632. In the same year he pleaded several causes before the parliament of Paris, but illness induced him to abandon the legal profession for the church. He became prior of Montdidier without taking holy orders, and lived for some years in the household of Cardinal de Retz (then coadjutor to the archbishop of Paris), where he had leisure for literary pursuits. Some time after 1648 he quarrelled with his patron and withdrew to a house in the cloister of Notre-Dame, where he gathered round him on Wednesday evenings those literary assemblies which he called "Mercuriales," Chapelan, Pellisson, Conrat, Sarrazin and Du Bos were among the habitues. He was admitted to the Della Cruscan Academy of Florence, but his caustic sarcasm led to his exclusion from the French Academy. Ménage made many enemies and suffered under the satire of Boileau and of Molliere. Molliere immortalized him as the pedant Vadius in Les Femmes savantes, a portrait Ménage pretended to ignore. He died in Paris on the 23rd of July 1692.

Of his works the following may be mentioned: Poemata latina, gallica, greeca, et italicâ (1650); Origini della lingua italiana (1650); Dictionnaire étymologique (1650 and 1670); Observations sur la langue française (1672–1676), and Anti-Bolléi (1690).

MENAGERIE, a collection of wild animals kept for show or exhibition. The word is particularly applied to travelling exhibitions of wild animals, attached to a circus or other show, and "zoological gardens" (q.v.) being the term generally applied to large collections, whether stationary or permanent exhibitions, arranged on a scientific system. The French ménagerie (from ménage, O. Fr. message, Lat. mansionaticum, mansio, house, cf. manage) originally meant the administration of a household or farm, with special reference to the live stock.

MENAHEM (Hebrew for "consoiler"), a king of Israel. He was the son of Gadi (i.e. perhaps, a man of Gad), and during the disturbances at the death of Jeroboam II. seized the throne and reigned ten years (2 Kings xv. 14–18). The scene of his revolt was Tirzah, the old seat of the kings of Israel between Jeroboam I. and Omri (which period the present closely resembles), and it was only after perpetrating nameless cruelties at Tappuah1 on the border of Ephraim and Mannaasheh that the counter revolt of Shalum, son of Jabesh (perhaps a Gileadite, was suppressed. Towards the end of his reign Tigger-Plesier IV. marched against north Syria, and among his tributaries mentions a people called the Jehothamites together with Rezia, Danasans, and a people of Tyre, Geba, &c. (c. 728 B.C.). According to the Old Testament account the Assyrian king even advanced against Israel, and only withdrew in consideration of a tribute amounting to about £4,000,000. A thousand talents (i.e. about 3,000,000 shekels) was raised by assessing every wealthy person at 50 shekels. The act was hardly popular, and the internal troubles which he had quelled

1 Scarcely Tiphah (2 Kings xv. 16) on the Ephrates.
2 The identification of the Israelite king with Me-ni-hi-im (im)-mi of Sa-me-ni-na-al on the Ass. inscription has been unnecessarily doubted.
broke out again at or shortly after his death. The Gileadites again conspired, and having slain his son Pekahiah set up Pekah the son of Remaliah in his place.¹ This meant a return to an anti-Assyrian policy. (See AHAD.)

**MENAI STRAITS,** a channel of the Irish Sea, separating Anglesea from Carnarvonshire, N. Wales, extending 14 m. from Beaumaris to Abermenai, and varying in breadth from 200 yds. to 2 m. It is famous for the suspension and tubular bridges which cross it. The suspension bridge carries the Holyhead road from Bangor. Designs were prepared by T. Telford. It was begun in 1819; the first chain carried over in April 1825; the last in July of the same year, and the bridge opened to the public the 30th of January 1826. The cost was £120,000. The length of the chains (from rock-fastenings) is 1715 ft., and between the piers 590 ft.; the length of the roadway between the piers is 550 ft. and the total roadway length 1000 ft.; the height of the roadway from the spring tide high-water level is 100 ft.; the breadth of the roadway including two carriage-ways and a footpath is 30 ft. The sixteen suspending chains are carried 60 ft. through rock. Their sustaining power has been calculated at 250 tons; while the weight of the suspended part of the bridge is only 489 tons. During a gale a slight oscillation is noticeable on the bridge itself and from the shore. The tubular bridge carries the London & North Western railway. Here the channel is about 1100 ft. wide, and divided in the middle by the Britannia Rock, bare at low water. The tide generally rises 20 ft., with great velocity. The principal measurements are: each abutment 176 ft.; from abutment to side tower, 230 ft.; from side tower to central tower, 460 ft.; breadth of each side tower at road-level, 32 ft.; breadth of centre tower, 45 ft. 5 in. The total length of the roadway is 1841 ft. 5 in. The Britannia bridge measures at its base 523 ft., with a total height of 230 ft. There are 101 ft. between the sea at high tide and the bridge roadway bottom. The limestone used is from Penmon, 4 m. from Beaumaris. Four stone lions couchant guard the approaches to the bridge. The first tube of the tubular bridge was deposited in its place on the 9th of November 1840, the last on the 13th of September 1850. The total cost was £621,865. The engineer of the tubular bridge was Robert Stephenson, who was assisted by Sir William Fairbairn and Eaton Hodgkinson.

**MENAM,** or ME NAM (literally the “mother water” or “main river”), a river of Siam, the chief highway of the interior, on whose yearly rise and fall depends the rice crop of Lower Siam. Rising in the Lao or Siamese Shan state of Nan, at a height of 1400 ft. upon the shoulders of the mountain mass of Doi Luang, it is first known as the Nam Ngob, after a village of that name. As the Nam Nan, still a mountain stream, it flows southward through the state so named between high forested ranges, and, notwithstanding the frequent rapids along its course, the natives use it in dug-outs for the transport of hill produce. From Uttaradit, where it leaves the hills of the Lao country, it flows southward through the plain of Lower Siam, and is navigable for about 150 miles in the rainy season. It is here known as the Nam, or Menam Fichai. Below Fichai the river flows through forest and swamp, the latter providing vast overflow basins for the yearly floods. Thousands of tons of fish are caught and cured here during the fall of the river after the rains. Below Pitsunalok the waters of the Menam Yom, the historic river of Siam, upon which two of its ancient capitals, Sawankalok and Sukotai, were situated, meander by more than one tortuous clayey channel to the main river, and combine to form the Nam Po. At Paknam Po the main western tributary comes in, the shallow Me Ping, the river of Raheng and Chieng Mai, bringing with it the waters of the Me Wang. As the chief duty-station for teak, which is floated in large quantities down all the upper branches of the river and as a place of transshipment for boats, Paknam Po is an important and growing town. From this point southwards the river winds by many channels through the richest and most densely populated portion of Siam. Above Chantaburi the Chachin branches off, forming the main western branch of the Menam, and falling into the gulf at a point about 24 m. west of the bar of the main or Bangkok river. At Ayuthia, another of the ancient capitals of Siam, the Nam Sak flows in from the north-east, an important stream affording communication with the rich tobacco district of Petchabun, and draining the western slopes of the Korat escarpment.

**MENANDER** (342–291 B.C.), Greek dramatist, the chief representative of the New comedy, was born at Athens. He was the son of well-to-do parents; his father Diopeithes is identified by some with the Athenian general and governor of the Thracian Chersonese known from the speech of Demosthenes De Cher- soneo. He doubtless derived his taste for the comic drama from his uncle Alexis (q.v.). He was the friend and associate, if not the pupil, of Theophrastus, and was on intimate terms with Demetrius of Phalerum. He also enjoyed the patronage of Ptolemy Soter, the son of Lagus, who invited him to his court. But Menander, preferring independence and the company of his mistress Glycera in his villa in the Peireaus, refused. According to the note of a scholar on the Ibis of Ovid, he was drowned while bathing; his countrymen built him a tomb commemorating the road leading to Athens, where it was seen by Pausanias. A well-known statue in the Vatican, formerly thought to represent Marius, is now generally supposed to be Menander (although some distinguished archaeologists dispute this), and has been identified with his statue in the theatre at Athens, also mentioned by Pausanias.

Menander was the author of more than a hundred comedies, but only gained the prize eight times. His rival in dramatic art and also in the affections of Glycera was Philemon (q.v.), who appears to have been more popular. Menander, however, believed himself to be the better dramatist, and, according to Aulus Gellius, used to ask Philemon: “Don’t you feel ashamed whenever you gain a victory over me?” According to Caecilius of Calacte (Porphyry in Eusebius, Praep. evan. x. 13) he was guilty of plagiarism, his Δεσδοκίων being taken bodily from the Olowoes of Antiphanes. But, although he attained only moderate success during his lifetime, he subsequently became the favourite writer of antiquity. Copies of his plays were known to Suidas and Eustathius (10th and 11th centuries), and twenty-three of them, with commentary by Psellus, were said to have been in existence at Constantinople in the 16th century. He is praised by Plutarch (Comparison of Menander and Aristophanes) and Quintilian (Instil. x. 1. 69), who accepted the tradition that he was the author of the speeches published under the name of the Attic orator Charisius. A great admirer and imitator of Euripides, he resembles him in his keen observation of practical life, his analysis of the emotions, and his fondness for moral maxims, many of which have become proverbial: “The property of friends is common,” “Whom the gods love die young,” “Evil communications corrupt good manners” (from the Thais, quoted in 1 Cor. xv. 33). These maxims and others were imitated in Menander’s works, and, with additions from other sources, were edited as Μενανδρον μικτοχα, a kind of moral textbook for the use of schools.

Menander found many Roman imitators. The Eunuchus, Andria, Heautontimorumenos and Adelphi of Terence (called by Caesar “dimidiatus Menander”) were avowedly taken from Menander, but some of them appear to be adaptations and combinations of more than one play; thus, in the Andria were combined Menander’s Άνδρα and Περισθα, in the Eunuchus the Ευνοθαος and Κώλες, while the Adelphi was compiled partly from Menander and partly from Diphilus. The original of Terence’s Hecyra (as of the Phormio) is generally supposed to be, not Menander, but Apollodorus of Carystus. The Bacchides and Stichus of Plautus were probably based upon Menander’s Δία Ιερατείας and Φιλαδέλφον, but the Poenula does not seem to be from the Βοιωτία, nor the Μεστελλαία from the Πάμα, in spite of the similarity of titles. Caecilius Statius, Lucius Lavinius, Turpilius and Attilus also imitated Menander. He was further credited with the authorship of some epigrams of doubtful

¹The chronology in xv. 2, 23, 32, appears to confuse Pekah and Pekahiah, and the view has been held that they were originally one and the same; cf. Cheyne, Encycl. Bibl., col. 3643.
That the old coins of Apollodotos and Menander, with Greek legends, were still in currency in Barygaza (mod. Broach), the great port of Gujarat, about A.D. 70 we are told by the Periplus maris Erythraei, 48. We possess many of these coins, which follow the Indian standard and are artistically degenerate as compared with the earlier Graeco-Bactrian and Graeco-Indian coins, with bilingual legends (Greek and Kharoshthi, see Bactria). Apollodotos, who must have been the earlier of the two kings, bears the titles Soter, Philopator, and “Great King”; Menander, who must have reigned a long time, as his portrait is young on some coins and old on others, calls himself Soter and “Just” (bikatos). Their reigns may be placed about 140–80 B.C. Menander appears in Indian traditions as Milinda; he is praised by the Buddhists, whose religion he is said to have adopted, and who in the Milindapana or Milinda Patho (see below), “the questions of Milinda” (Ryhs Davids, Sacred Books of the East, xxv, xxxvi) relate his discourses with the wise Nāgasena. According to the Indians, the Greeks conquered Ayodyha and Pataliputra (Palmbothera, mod. Patna); so the conjecture of Cunningham that the river Isurus of Strabo is the Son, the great southern tributary of the Ganges (now Patna), may be true. The Buddha praised the valor, energy, and wisdom of “Milinda”; and a Greek tradition preserved by Plutarch (Proc. rep. gsr. 28, 6) relates that “when Menander, one of the Bactrian kings, died on a campaign after a mild rule, all the subject towns disputed about the honour of his burial, till at last his ashes were divided between them in equal parts.” (The Buddhist tradition relates a similar story of the relics of Buddha.) Besides Apollodotos and Menander, we know from the coins a great many other Greek kings of western India, among whom two with the name of Straton are most conspicuous. The last of them, with degenerate coins, seems to have been Hermaeus Soter. These Greek dynasts may have maintained themselves in some part of India till about 40 B.C. But at this time the west, Kabul and the Punjab were already in the hands of a barbarous dynasty, most of whom have Iranian (Parthian) names, and who seem therefore to have been of Arsacid origin (cf. Vincent A. Smith, “The Indo-Parthian Dynasties from about 120 B.C. to A.D. 100,” in Zeitschrift der deutschen morgenländischen Gesellschaft, 1906, lx. 69 sqq.). Among them Manes, two kings named Azes, Vonones and especially Gondophares or Hyndphares are the most conspicuous. The latter, whose date is fixed by an inscription from the Kabul Valley dated from the year 103 of the Samvat era (= A.D. 46), is famous by the legend of St Thomas, where he occurs as king of India under the name of Gundaphar. Soon afterwards the Mongolian Scythians (called Saka by the Indians), who had conquered Bactria in 130 B.C., invaded India and founded the great Indo-Scythian kingdom of the Kushan dynasty. (See Bactria; and Persia: Ancient History.)

The Milinda Patho is preserved in Pali, in Ceylon, Burma and Siam, but was probably composed originally in the extreme north-west of India, and in a dialect spoken in that region. Neither the Pali nor the author’s names have been preserved, but it is thought there have been about the 2nd century of our era. The work is entitled Milinda Patho—that is, The Questions of King Milinda. In it the king is represented as propounding to a Buddhist Bhikshu named Apardathu a number of problems, puzzles or questions in religion and philosophy; and as receiving, in each case, a convincing reply. It is a matter of very little importance whether a tradition of some such conversations having really taken place had survived to the time of the Buddhaghosa, or whether he composed both problems and answers; and his work is an historical romance, written to discuss certain points in the faith, and to invest the discussion with the interest arising from the story in which it is presented, in the shape of a question and answer. Giving the past and present lives of Milinda and Nāgasena, is admirably adapted to fill the reader with the idea of the great ability and distinction of the two disputants. The questions chosen are human and familiar, while the answers, which are general and spiritual, give the usual taste of the India of that age. And the style of the book is very attractive. Each particular point is kept within easy limits of space, and is treated in a popular way. But the earnestness of the author is not concealed, and he occasionally rises into a real eloquence. The work is several times quoted as authority, by Buddhaghosa, who wrote about A.D. 450, and it is the only work, not in the canon, which receives this honour.
The Milinda has been edited in Pali by V. Trenckner, and translated into English by the present writer, with introductions in which the historical and critical points made in this article are discussed in detail. There is space here to mention only one further fact. M. Sylvain Lévy, working in collaboration with W. Specht, has shown that there are two, if not three, Chinese works, written between the 5th and 7th centuries, on the Questions of Milinda. They purport to be translations of Indian works. They are not, however, attempts to render the Pali text word for word; there are additions, the substance of the earlier part of the Pali work; and are probably derived from a recension that may be older than the Pali.

(M. T. R. D.)

MENANDER, of Laodicea on the Lycus, Greek rhetorician and commentator. Two incomplete treatises on epideictic (or show) speeches have been preserved under his name, but it is generally considered that they cannot be by the same author. Bursian attributes the first to Menander, whom he placed in the 4th century, and the second to an anonymous rhetorician of Alexandria Troas, who possibly lived in the time of Diocletian. Others, from the superscription of the Paris MS., assign the first to Genethlius of Petrae in Palestine. In view of the general tradition of antiquity, that both treatises were the work of Menander, it is possible that the author of the second was not identical with the Menander mentioned by Suidas, since the name is of frequent occurrence in later Greek literature. The first treatise, entitled Διανέρπες τῶν ἐπειδεκτικῶν, discusses the different kinds of epideictic speeches; the second, Περὶ ἐπειδεκτικῶν, has special titles for each chapter.

Text in L. Spengel’s Rhetores graeci, iii. 329—446, and in C. Bursian’s “ Der Rhetor Menandros und seine Schriften ’’ in Abhandl. der bayer. Akad. der Wissenschaften, xvi. (1882); see also W. Nitsche, Der Rhetor M. und die Scholen zu Demosthenes; J. E. Sandys, Life of Classical Scholarship (1906), i. 538; W. Christ, Gesch. der griechischen Literatur (1889), § 550.

MENANDER PROTECTOR (Πορττροκρις, i.e. one of the imperial bodyguards), Byzantine historian, was born in Constantinople in the middle of the 6th century A.D. The little that is known of his life is contained in the account of himself quoted by Suidas. He at first took up the study of law, but abandoned it for a life of pleasure. When his fortunes were low, the patronage accorded to literature by the emperor Maurice (582) encouraged him to try writing history. He took as his model Agathias (p.v.), who like him had been a jurist, and his history begins at the point where Agathias leaves off. It embraces the period from the arrival of Constantine Hunch purchased Thrace during the reign of Justin I to the death of the emperor Tiberius in 582. Considerable fragments of the work are preserved in the excerpts of Constantine Porphyrogenitus and in Suidas. Although the style is sometimes bombastic, it is considered trustworthy and is one of the most valuable authorities for the history of the 7th century, especially on geographical and ethnographical matters. He was an eye-witness of some of the events he describes. Like Agathias, he wrote epigrams, one of which, on a Persian magus, who became a convert to Christianity and died the death of a martyr, is preserved in the Greek anthology (Anth. Pal. i. 101).

The fragments will be found in C. W. Müller, Frag. hist. graec. lv. 2002; in Magie, Prose Rhetorik, ed. ii., and L. Dindorf, Historici graeci minores, ii.; see also C. Krumbacher, Geschichte der byzantinischen Literatur (1897).

MENANGKABOS, the most civilized of all the true Malays of Sumatra, inhabiting the mountains above Padang. Their district is regarded as the cradle of the Malay race, and thence began, about 1700, those migrations which ended in the true Malays becoming the dominant race throughout the peninsula and the Malay Archipelago. The Menangkabos are said to be the original conquerors of the island, and the real form of the word is Menang-Karbau ("victory of the buffalo"), in reference to a local legend of a fight between a Sumatran and Javanese buffalo, ending in victory for the former. Though converts to Islam, the ancient confederate village communities and the matriarchal system still exist. The people are divided into clans, the chiefs together forming the district council. Early in the 19th century a religious sect was founded among the Menangkabos, known as "Padris" from its zealous proselytism, or Orang puti (white men) from the converts being dressed in white. The tendency was towards asceticism, the chief tenet being the prohibition of opium, the use of which was made a capital offence. The sect brought a large portion of the interior of Sumatra under its rule, but the neighbouring tribes asked the Dutch to protect them, and this led to the Netherlands government acquiring the Menangkabo territory.

MÉNANT, JOACHIM (1820—1899), French magistrate and orientalist, was born at Cherbourg on the 16th of April 1820. He was educated for the law, and became vice-president of the civil tribunal of Rouen in 1878, and a member of the cour d'apel three years later. But he became best known by his studies on the cuneiform inscriptions. Among his works on the subject of Assyriology are: Recueil d'alphabets des tercires cunéiformes (1860); Exposé des éléments de la grammaire assyrienne (1868); Le Sylabaire assyrien (2 vols., 1869—1873); Les Langues perdues de la Perse et de l'Assyrie (2 vols., 1885—1886); Les Pierres gravées de la Haute-Asie (2 vols., 1883—1886). He also collaborated with Julius Oppert. He was admitted to the Academy of Inscriptions in 1887, and died in Paris on the 30th of August 1899.

His daughter Delphine (b. 1850) received a prize from the Academy for her Les Paris, histoire des communautés soro-astroîniennes de l'Inde (1898), and was sent in 1900—1901 to British India on a scientific mission, of which she published a report in 1902.

MÉNARD, LOUIS NICOLAS (1822—1901), French man of letters, was born in Paris on the 19th of October 1822. His versatile genius occupied itself in turn with chemistry, poetry, painting and history. In 1843 he published, under the pseudonym of L. de Senneville, a translation of Prométée détêt. Turning to chemistry, he discovered collodion in 1846, but its value was not recognized at the time; and its application later to surgery and photography brought him no advantage. Louis Ménard was a socialist, always in advance of the reform movements of his time. After 1848 he was condemned to imprisonment for his Prologue d'une révolution. He escaped to London, returning to Paris only in 1852. Until 1860 he occupied himself with classical studies, the fruits of which are to be seen in his Histoire des arts (1864), Polybes ou l'histoire de Grecque (1865), and two academic theses, De saeculo aetatis graeco et La Morale avant les philosophes (1860). The next ten years Ménard spent chiefly among the Barbizon artists, and he exhibited several pictures. He was in London at the time of the Commune, and defended with his pen. In 1887 he became professor at the École des Arts décoratifs, and in 1895 professor of universal history at the Hôtel de Ville in Paris. His Mélanges d'un poète mystique (1870), which contained sonnets, philosophical dialogues and some stories, was followed in 1896 by Poesies et révélations d'un poète mystique. Ménard died in Paris on the 12th of February 1901.

His works include: Histoire des anciens peuples de l'Orient (1882); Histoire des Israélites d'après l'extériorité biblique (1883), and Histoire de la Méditerannée 1808—1860 (1888—1889), in connection of which he was one of the men behind the opening of Maurice Barrès’ Voyage de Sparte.

MENASHA (an Indian word meaning “thorn” or “island”), a city of Winnebago county, Wisconsin, U.S.A., 88 m. N. of Milwaukee, and 14 m. N. of Oshkosh, attractively situated at the N. extremity of Lake Winnebago at its outlet into the Fox river. Pop. (1890), 4581; (1900), 5589 (1535 foreign-born); (1905, state census), 5960; (1910), 6081. Menasha is served by the Minneapolis, St Paul & Sault Ste Marie, the Chicago, Milwaukee & St Paul, and the Chicago & North-Western railways, and by an inter-urban electric railway system. Several bridges across the Fox River connect Menasha with Neenah, with which it really forms one community industrially. Doty Island, at the mouth of the river and divided about equially between the cities, is a picturesque and popular summer resort.
Menasseh had good water power and among its manufactures are paper and sulphite pulp, lumber, wooden-ware and cooperative products, woolen and knit goods, leather, boats and bricks. The first white man to visit the site of Menasseh was probably Jean Nicolet, who seems to have come in the winter of 1634-1635 and to have found here villages of Fox and Winnebago Indians. Subsequently there were French and English trading posts here. The city was settled permanently in 1848, and was chartered in 1874.

**Menasseh Ben Israel** (c. 1604-1657), Jewish leader, was born in Lisbon about 1604, and was brought up in Amsterdam. His family had suffered under the Inquisition, but found an asylum first in La Rochelle and later in Holland. Here Menasseh rose to eminence not only as a rabbi and an author, but also as a printer. He established the first Hebrew press in Holland.

One of his earliest works *El Conclusor* won immediate reputation. It was an attempt at reconciliation between apparent discrepancies in various parts of the Old Testament. Among his correspondents were Vossius, Grocius and Huet. In 1638 he decided to settle in Brazil, as he still found it difficult to provide in Amsterdam for his wife and family, but this step was rendered unnecessary by his appointment to direct a college founded by the Pereiras.

In 1644 Menasseh met Antonio de Montesinos, who persuaded him that the North-American Indians were the descendants of the lost ten tribes of Israel. This supposed discovery gave a new impulse to Menasseh's Messianic hopes. But he was convinced that the Messianic age needed as its certain precursor the settlement of Jews in all parts of the known world. Filled with this idea, he turned his attention to England, whence the Jews had been expelled since 1290. He found much Christian support in England. During the Commonwealth the question of the readmission of the Jews was often mooted under the growing desire for religious liberty. Besides this, Messianic and other mystic hopes were current in England.

In 1650 appeared an English version of the *Hope of Israel*, a tract which deeply impressed public opinion. Cromwell had been moved to sympathy with the Jewish cause partly by his tolerant leanings, but chiefly because he foresaw the importance for English commerce of the presence of the Jewish merchant princes, some of whom had already found their way to London. At this juncture Jews received full rights in the colony of Surinam, which had been English since 1650. In 1655 Menasseh arrived in London. It was during his absence that the Amsterdam Rabbis excommunicated Spinoza, a catastrophe which probably has been avoided had Menasseh—Spinoza's teacher—been on the spot.

One of his first acts on reaching London was the issue of his *Humble Addresses* to the Lord Protector, but its effect was weakened by the issue of Prynne's able but unfair *Short Demurrer*. Cromwell summoned the Whitelhall Conference in December of the same year. To this conference were summoned some of the most notable statesmen, lawyers and theologians of the day. The chief practical result was the declaration of Judges Glynne and Steele that "there was no law which forbade the Jews' return to England." Though, therefore, nothing was done to regularize the position of the Jews, the door was opened to their gradual return. Hence John Evelyn was able to enter in his *Diary* under the date December 7, 1655, "I was received, and thence admitted." But the attack on the Jews by Prynne and others could not go unanswered. Menasseh replied in the finest of his works, *Vindiciae judaicorum* (1656). "The best tribute to its value is afforded by the fact that it has since been frequently reprinted in all parts of Europe when the calumnies it denounced have been revived" (L. Wolf). Among those who used in this way Menasseh's *Vindiciae* was Moses Mendelssohn (q.v.).

Soon after Menasseh left London Cromwell granted him a pension, but he died before he could enjoy it. Death overtook him at Middleburg, as he was conveying the body of his son Samuel home for burial.

Menasseh Ben Israel was the author of many works, but his English tracts remain the only ones of importance. His *De termino viuae* was translated into English by Pococke, and his *Conciliator* by G. H. Lindo. Among his other works were a ritual compendium *Tesor unsuccessful, and a treatise in Hebrew on immortality (*Nishmath hayim*). He was a friend of Rembrandt, who painted his portrait and engraved four etchings to illustrate his *Piedra gloriosa*. These are preserved in the British Museum.

**Mencius**, the Latinized form of Măng-tse, "Mr Măng," or "Măng the philosopher," a Chinese moral teacher whose name stands second only to that of Confucius. His statue or spirit-tablet (as the case may be) has occupied, in the temples of the sage, since our 12th century, a place among "the four assessors," and since A.D. 1530 his title has been "the philosopher Măng, sage of the second degree."

The Măngs or Măng-suns had been in the time of Confucius one of the three great clans of Lâu (all descended from the marquis Hwan, 711-694 B.C.), which he had endeavoured to curb. After his death Confucius had decreed that the descendants of the Măngs should settle in T אירוע, a small adjacent principlality, the name of which remains in Tấu haen, a district of Yen-chu Shan-tung. A magnificent temple to Mencius is the chief attraction of the district city. The large marble statue of Mencius in the courtyard shows much artistic skill, and gives the impression of a man strong in body and mind, thoughtful and fearless. His lineal representative lives in the city, and thousands of Măngs are to be found in the neighbourhood.

Mencius, who died in the year 289 B.C., had lived to a great age—some say to his eighty-fourth year, placing his birth in 372 B.C., and others to his ninety-seventh, placing it in 385. All that we are told of his father is that he died in the third year of the child, who was thus left to the care of his mother. Her virtues and dealings with her son were celebrated by a great writer in the 1st century before our era, and for two thousand years she has been the model mother of China.

Mencius is more than forty years old when he comes before us as a public character. He must have spent much time in study, investigating questions as to the fundamental principles of morals and society, and brooding over the condition of the country. The history, the poetry, the institutions and the great men of the past had received his attention. He intimates that he had been in communication with men who had been disciples of Confucius. That sage had become to him the chief of mortal men, the object of his untried admiration; and in the doctrines which he had taught Mencius recognized the truth for want of an appreciation of which the bonds of order all round him were being relaxed, and the kingdom hastening to anarchy.

When he first comes forth from Tấu, he is accompanied by several eminent disciples. He had probably imitated Confucius in becoming the master of a school, and encouraging the resantar to it of inquiring minds that he might resolve their doubts and unfold to them the right methods of government. One of his sayings is that it would be a greater delight to the superior man to give the youth of brightest promise round him and to teach and train them than to enjoy the revenues of the kingdom. His intercourse with his followers was not so intimate as that of Confucius had been with the members of his selected circle; and, while he maintained his dignity among them, he was not able to secure from them the same homage and reverent admiration.

More than a century had elapsed since the death of Confucius, and during that period the feudal kingdom of Châu had been showing more and more of the signs of dissolution, and portentous errors that threatened to upset all social order were widely disseminated. The sentiment of loyalty to the dynasty had disappeared. Several of the marquesses and other feudal princes of earlier times had usurped the title of king. The smaller fiefs had been absorbed by the larger ones, or reduced to helpless dependence on them. Tsin, after greatly extending its territory,
had broken up into three powerful kingdoms, each about as large as England. Mencius found the nation nominally one, and with the traditions of two thousand years affirming its essential unity, but actually divided into seven monarchies, each seeking to subdue the others under itself. The consequences were constant warfare and chronic misery.

In Confucius’s time we meet with recluse who had withdrawn in disgust from the world and its turmoil; but these had now given place to a class of men who came forth from their retirements with arts of war or schemes of policy which they recommended to the contending chiefs, ever ready to change their allegiance as they were moved by whim or interest. Mencius was once asked about two of them, “Are they not really great men? Let them be angry, and all the princes are afraid. Let them live quietly, and the flames of trouble are everywhere extinguished.” He looked on them as little men, and delighted to proclaim his idea of the great man in such language as the following:

“To dwell in love, the wide house of the world, to stand in propriety, the correct seat of the world, and to walk in righteousness, the great path of the world; when he obtains his desire for office, to practise his principles for the good of the people, and when that desire is disappointed, to practise them alone; to be above every pride and vanity and make the space and time of poverty and mean condition to make swerve from the right, and of power and force to make bend—these characteristics constitute the great man.”

Most vivid are the pictures which Mencius gives of the condition of the people in consequence of the wars of the states.

“The royal ordinances were violated; the multitudes were oppressed; the supplies of food and drink flowed away like water.” It is not wonderful that, when the foundations of government were thus overthrown, speculations should have arisen that threatened to overthrow what he considered to be the foundations of truth and all social order. “A shrill-thinking barbarian from the south,” as Mencius called him, proclaimed the dissolution of ranks, and advocated a return to primitive simplicity. He and his followers maintained that learning was quackery, and statesmanship craft and oppression, that prince and peasant should be on the same level, and every man do everything for himself. Another, called Yang-chü, denied the difference between virtue and vice, glory and shame. It was the same with all at death. The conclusion therefore was: “Let us eat and drink; let us gratify the ears and eyes, get servants and maidsens, beauty, music, wine; when the day is insufficient, carry it on through the night. Each one for himself.” Against a third heresiarcl, of a very different stamp, Mencius felt no less indignation. This was Mo Ti, who found the source of all the evils of the time and of all time in the want of mutual love. He taught, therefore, that men should love others as themselves; princes, the states of other princes as much as their own; children, the parents of others as much as their own. Mo, in his gropings, had got hold of a noble principle, but he did not apprehend it distinctly nor set it forth with discrimination. To our philosopher the doctrine appeared contrary to the Confucian orthodoxy about the five relations of society; and he attacked it without mercy and with an equal confusion of thought. “Yang’s principle,” he said, “is ‘each one for himself,’ which does not acknowledge the claims of the sovereign. Mo’s is ‘to love all equally,’ which does not acknowledge the peculiar affection due to a father. But to acknowledge neither king nor father is to be in the state of a beast. The way of benevolence and righteousness is stopped up.”

On this ocean of lawlessness, wickedness, heresies and misery Mencius looked out from the quiet of his school, and his heart was stirred to attempt the rescue of the people from misrule and error. “If Heaven,” he said, “wishes that the kingdom should enjoy tranquillity and good order, who is there besides me to bring it about?” He formed his plan, and proceeded to put it in execution. He would go about among the different kings till he should find one among them who would follow his counsels and commit to him the entire administration of his government. That obtained, he did not doubt that in a few years there would be a kingdom so strong and so good that all rulers would acknowledge its superiority, and the people hasten from all quarters to crown its sovereign as monarch of the whole of China. This plan was much the same as that of Confucius had been; but, with the bolder character that belonged to him, Mencius took in one respect a position from which “the master” would have shrank. The former was always loyal to Chü, and thought he could save the country by a reformation; the latter saw the day of Chü was past, and the time was come for a revolution. Mencius’s view was the more correct, but he was not wiser than the sage in forecasting for the future. They could think only of a reformed dynasty or of a changed dynasty, ruling according to the model principles of a feudal constitution, which they described in glowing language. They desired a repetition of the golden age in the remote past; but soon after Mencius disappeared from the stage of life there came the sovereign of Ch’in, and solved the question with fire and sword, introducing the despotic empire which has since prevailed.

The question may be asked, “How, in the execution of his plan, was Mencius, a scholar, without wealth or station, to find admission to the courts of lawless and unprincipled kings, and acquire the influence over them which he expected?” The answer can only be found by bearing in mind the position accorded from the earliest times in China to men of virtue and ability. The same written character denotes both scholars and officers. They are at the top of the social scale—the first of the four classes into which the population has always been divided. This appreciation of learning or culture has exercised a powerful influence over the government under both conditions of its existence; and out of it grew the system of making literary merit the passport to official employment. The ancient doctrine was that the scholar’s privilege was from Heaven as much as the sovereign’s right; the modern system is a device of the despotic rule to put itself in Heaven’s place, and have the making of the scholar in its own hands. The feeling and conviction out of which the system grew prevailed in the time of Mencius. The dynasties that had successively ruled over the kingdom had owed their establishment not more to the military genius of their founders than to the wisdom and organizing ability of the learned men, the statesmen, who were their bosom friends and trusted counsellors. Why should not he become to one of the princes of his day what I Yin had been to Thang, and Th’ai-kung Wang to King Wän, and the duke of Chü to Wü and Ch’ang? But, though Mencius might be the equal of any of those worthies, he knew of no prince like Thang and the others, of noble aim and soul, who would adopt his lessons. In his eagerness he overlooked this condition of success for his enterprise. He might meet with such a ruler as he looked for, or he might reform a bad one, and make him the coadjutor that he required. On the strength of these peradventures, and attended by several of his disciples, Mencius went for more than twenty years from one court to another, always baffled, and always ready to try again. He was received with great respect by kings and princes. He would not enter into the service of any of them, but he occasionally accepted honorary offices of distinction; and he did not scruple to receive large gifts which enabled him to live and move about as a man of wealth. In delivering his message he was as fearless and outspoken as John Knox. He lectured great men, and ridiculed them. He unfolded the ways of the old sage kings, and pointed out the path to universal sway; but it was all in vain. He could not give any of them his courage to permit hisesy with strong arguments and expose it with withering sarcasm; but he could work no deliverance in the earth. The last court at which we find him was that of Lü, probably in 316 B.C. The marquis of that state had given office to Yo-ch’ang, one of Mencius’s disciples, and he hoped that this might be the means of a favourable hearing for himself. So it had nearly happened. On the suggestion of Yo-ch’ang the marquis had ordered his carriage to be yoked, and was about to step into it and proceed to bring Mencius to his palace, when an unworthy
MENCUS

favourite stepped in and diverted him from his purpose. The disciple told his master what had occurred, reprobating the favourite for his ill-timed intervention; Mencius, whenever said to him, "A man's advancement or the arresting of it may seem to be effected by others, but is really beyond their power. My not finding in the marquis of Lü a ruler who would confide in me and put my lessons in practice is from Heaven."

Mencius accepted this incident as a final intimation to him of the will of Heaven. He had striven long against adverse circumstances, but now he bowed in submission. He withdrew from courts and the public arena. According to tradition he passed the last twenty years of his life in the society of his disciples, discoursing to them, and giving the finishing touches to the record of his conversations and opinions, which were afterwards edited by them, and constitute his works. Mencius was not so oracular, nor so self-contained, as Confucius; but his teachings have a vivacity and sparkle all their own.

Mencius held with Confucius—and it was a doctrine which had descended to them both from the remotest antiquity—that royal government was an institution upholding the ancient order of things. He said, "Heaven himself produced the people, appointed them for rulers, and appointed for them teachers, who should be assisting to God." Our philosopher, adopting this doctrine, was led by the manifest incompetency of all the forms of government, which is in them already a contradiction. The individual appointment of Heaven had fallen or ought to fall, and he concluded that this could be ascertained only from his personal character and his conduct of affairs. The people must find out the will of Heaven as to who should govern them, as the trees of the forest find out the force applied which causes them. When men do what is not good, their nature has been dealt with in this way."

With various, but equally felicitous, illustration he repeated to his different opponents. Sometimes he may seem to express himself too strongly, and at other times to mince his words, that he might be more forcible in the expression of our nature in its ideal, and not as it actually is—as we may ascertain, by an analysis of it, that it was intended to be, and not as it has been made by the force of human nature to accord with the result of cultivation. In opposition to all these views Mencius contended that the nature of man is good. "Water," he said, "will flow indifferently to the east or west; but will it flow inwardly to the east or west?"

Mencius insisted on the constituents of human nature, dwelling especially on the principles of benevolence, righteousness, propriety, and wisdom or knowledge, the last including the judgment of conscience. "These," said he, "are not infused into us from without."

Menciusnpos Da. His reason for this deficiency is due to the selfish nature of our disposition, which has led to the four limbs. But man has also instincts and appetites which seek their own gratification without reference to righteousness or any other control. He met this difficulty by contending that human beings are designed to rule the lower. Some constituents of it are noble and some ignoble, some great and some small. The great must not be injured for the small, nor the noble for the ignoble.

One of his most vigorous indications of his doctrine is the following: "For the mouth to desire favours, the eye colours, the ear sounds, and the four limbs ease and rest belong to man's nature. An individual's lot may restrict him from the gratification of these, but they are not taken away. My master taught me that the nature demands that pleasure, and I will get it." On the other hand, there are love between father and son, righteousness between ruler and minister, the rules of ceremony between host and guest, those between a man and his wife, and those between a man and his father. These are the paths of Heaven, in the sages' fulfilling the heavenly course;—these are appointed (by Heaven). But they also belong to our nature, and the superior man will not say, 'The circumstances of my lot relieve me from them.'

In propounding the people to be made well off, Mencius taught that education should be provided for them all. He gave the marquis of Thang a programme of four kinds of educational institutions, which he wished him to establish in his state—in the villages and the towns, for the poor as well as the rich, so that none might be ignorant of his duties in the various relations of society. But after all, unless the people could get food and clothing by their labour, he had not much faith in the power of education to make them virtuous. Give him, however, a government fulfilling the conditions, and he had little doubt that the people would soon be a people, all contented, all virtuous. And he said nothing to prevent the realization of such a government. Any ruler might become, if he would, the minister of Heaven, who was his ideal, and immediate instance of a man so powerful. The people would flock to him as their parent, and help him to do justice on the foes of truth and happiness. Pulse and grain would be abundant as water and fire, and the multitudes, without founded, and well principled, would sit under the shade of their mulberry trees, and hail the ruler "king by the grace of Heaven."

Opinions were much divided among his contemporaries on the subject of human nature. Some held that the nature of man is good, and that others bad; thus it is that the best of men sometimes have bad sons, and the worst of men good sons. It was also maintained that the disposition of man is evil, and the cultivation of it is the result of cultivation. In opposition to all these views Mencius contended that the nature of man is good. "Water," he said, "will flow indifferently to the east or west; but will it flow inwardly to the east or west?"
The sense of shame is to a man of great importance. When one is ashamed of having been without shame, he will afterwards not have occasion for shame.

To nourish the heart there is nothing better than to keep the desires which we have. Here where desires are few; in some things he may not be able to keep his heart, but they will be few. Here is a man whose desires are many; in some things he may be able to keep his heart, but they will be few.

In the desert, submissively desires are characteristic of man. As embodied in his conduct, it may be called the path of duty.

There is an ordination for everything; and a man should receive submissively what may be correctly ascribed thereto. He who has received an ordination which is correctly ascribed to Heaven is beneath a tottering wall. Death sustained in the discharge of one's duties may be correctly ascribed to Heaven. Death under handcuffs and fetters cannot be correctly ascribed.

Two men distinguish themselves; they do not submit to him in heart. When he subdues them by virtue, in their hearts' core they are pleased, and sincerely submit.

Two translations of the works of Mencius are within the reach of European readers: that by Stanislaus Jullien, in Latin (Paris, 1824-1829); and that forming the second volume of Legge's Chinese Classics (Hong-Kong, 1862). The latter has been published at London (1875) without the Chinese text. See also E. Faber, The Mind of Mencius, or Political Economy founded on Moral Philosophy, translated from the German by A. B. Hutchinson (London, 1882).

MENDE, a town of south-eastern France, capital of the department of Lozère, 59 m. N.E. of Millau by rail. Pop. (1906), town 5346; commune 7007. Mende is picturesquely situated on the left bank of the Lot, and at the foot of the Mont-de-Clain, which rises 1000 ft. above the town, and terminates the Causses. The town is a native of the district. Its cathedral of St Peter was founded in the 14th century by Pope Urban V., a native of the district, but the two towers, respectively 280 and 210 ft. high, were added by Bishop François de la Rovère in the early part of the 16th century. Partly destroyed during the devastation of the town by the Protestants in 1570 and 1580, it was rebuilt in the 17th century, and in 1874 a statue of Urban V. was erected in front of it. A Renaissance tower of the ancient citadel now serves as the belfry of the church of the Penitents, and a 14th-century bridge crosses the Lot. The town is a convenient centre for visitors to the gorges of the Tarn. It is the seat of a prefect and a court of assizes, and has a tribunal of first instance and a chamber of commerce. The chief industry is the manufacture of serges and garnets; known as Mende stuffs, exported to Spain, Italy and Germany.

Mende (Mimate) grew up around the hermitage, partly excavated in the side of the Mimat cliff, to which St Privat, bishop of Javols, retired after the destruction of that town, and where he was subsequently slain by the Vandals, who had pursued him thither, about 408. In the 14th century the town became the civil, as it had previously been the ecclesiastical, capital of the Gévaudan district.

Mendeleeff, Dmitri Ivanovich (1834-1907), Russian chemist, the youngest of a family of seventeen, was born at Tobolak, Siberia, on the 7th of February (n.s.) 1834. After attending the gymnasium of his native place, he went to study natural science at St Petersburg, where he graduated in chemistry in 1856, subsequently becoming privotadzen. In 1861 he was appointed to the Heidelberg, where he started a laboratory of his own, but returning to St Petersburg in 1864, he became professor of chemistry in the technological institute there in 1863, and three years later succeeded to the same chair in the university. In 1869 he resigned the professorship, and in 1873 he was appointed director of the Bureau of Weights and Measures, a post which he occupied till his death.

Mendelev's original work covered a wide range, from questions in applied chemistry to the most general problems of chemical and physical theory. His name is best known for his work on the Periodic Law. Various chemists had traced numerical sequences among the atomic weights of some of the elements and noted connections between them and the properties of the different substances; but it was left to him to give a full expression to the generalization, and to treat it not merely as a system of classifying the elements according to certain observed facts, but as a "law of nature" which could be relied upon to predict new facts and to disclose errors in what were supposed to be old facts. Thus in 1871 he was led by certain gaps in his tables to assert the existence of three new elements so far unknown to the chemist, and to assign them definite properties. These three he called eka-boron, eka-aluminium, and eka-silicon; and his prophecy was completely vindicated within fifteen years by the discovery of gallium in 1875, scandium in 1879, and germanium in 1886. Again, in several cases he ventured to question the correctness of the "accepted atomic weights," on the ground that they did not correspond with the Periodic Law, and here also he was justified by subsequent investigation. In 1902, in an "attempt at a chemical conception of the ether," he put forward the hypothesis that there are in existence two elements of smaller atomic weight than hydrogen, and that the lighter of these is a chemically inert, exceedingly mobile, all-penetrating and all-pervading gas, which constitutes the aether. Mendelev also devoted much study to the nature of such "indefinite" compounds as solutions, which he looked upon as homogeneous liquid systems of unstable dissociating compounds of the solvent with the substance dissolved, holding the opinion that they are merely an instance of ordinary definite or atomic compounds, subject to Dalton's laws. In another department of physical chemistry he investigated the expansion of liquids with heat, and devised a formula for its expression similar to Gay-Lussac's law of the uniformity of the expansion of gases, while so far back as 1861 he anticipated T. Andrews' conception of the critical temperature of gases by defining the absolute boiling-point of a substance as the temperature at which cohesion and heat of vaporization become equal to zero and the liquid changes to vapour, irrespective of the pressure has on the system. Mendelev wrote largely on chemical topics, his most widely known book probably being The Principles of Chemistry, which was written in 1868-1879, and has gone through many subsequent editions in various languages. For his work on the Periodic Law he was awarded in 1882, at the same time as L. Meyer, the Davy medal of the Royal Society, and in 1905 he received its Copley medal. He died at St Petersburg on the 2nd of February 1907.

MENDELISM. To define what some biologists call Mendelism briefly is not possible. Within recent years there has come to biologists a new idea of the nature of living things, a new conception of their potentialities and of their limitations; and for this we are primarily indebted to the work of Gregor Mendel. Peasant boy, monk, and abbot of Brunn, this remarkable man at one time interested himself in the workings of heredity, and the experiments devised by him and carried out in his cloister garden are to-day the foundation of that exact knowledge of the physiological process of heredity which biologists are rapidly extending in various directions. This extension Mendel never saw. Born in 1822 he published the account of his experiments in 1865; but it was not until 1900, eighteen years after his death, that biologists came to appreciate what he had accomplished. That year marked the simultaneous rediscovery of Mendel's work by two distinguished biologists: de Vries, C. Correns and E. Tschermak. Henceforward Mendel's ideas have steadily gained ground, and, as the already strong body of evidence in their favour grows, they must come to exert upon biological conceptions an influence not less than those associated with the name of Darwin.

Dominant and recessive.—Mendel chose the common pea (Pisum sativum) as a subject for experiment, and investigated the effects of crossing different varieties. In his method he differed from previous investigators in concentrating his attention on the mode of inheritance of a single pair of alternative characters at a time. Thus on crossing a tall with a dwarf and paying attention to this pair of characters alone, he found that the hybrids (or F1 generation) were all tall and that no intermediates appeared. Accordingly he termed the tall character dominant and the dwarf character recessive. On allowing these hybrids to fertilize themselves in the ordinary
way he obtained a further generation which on the average was composed of three tails to one dwarf. Subsequent experiment showed that the dwarfs always bred true, as did also one out of every three tails; the two remaining tails behaved as the original hybrids in giving three tails to one dwarf. Having regard to the characters, tallness and dwarfliness, three and only three kinds of peas exist, viz. dwarfs which breed true, tails which breed true, and tails which give a fixed proportion of tails and dwarfs. The relation between these three forms may be briefly summarized in the subjoined scheme, in which pure tall and dwarf are represented by T and D respectively, while T denotes the tails which do not breed true. Experiments were also made with several other pairs of characters, and the same mode of inheritance was shown to hold good throughout.

**Unit-Characters.**—As Mendel clearly perceived, these definite results lead inevitably to a precise conception of the constitution of the reproductive cells, or gametes; and to appreciate fully the change wrought in our point of view necessitates a brief digression into the essential features of the reproductive process. A sexual process (see Sex) is almost universal among animals and plants, and consists essentially of the union of two gametes, of which one is produced by either parent. Every gamete contains small definite bodies known as chromosomes, and the number of these is, with few known exceptions, constant for the gametes of a given species. On the fusion of two gametes the resulting cell or zygote has therefore a definite structure, for it contains an equal number of chromosomes brought in by the paternal and by the maternal gametes—in the case of a plant by the pollen grain as well as by the ovule. By a process of repeated division the zygote gives rise to a plant (or an animal) whose cells apparently retain the double structure throughout. Certain of the cells of such a zygote become the germ cells and are set apart, as it were, for the formation of gametes. Histology has shown that when this occurs—i.e., the cells lose the double structure which they had hitherto possessed, and that as a result of the process known as the reduction division gametes are formed in which the number of chromosomes is one half of that which characterizes the cells of the zygote. It is generally acknowledged that the chromosomes play an important part in the hereditary process, and it is possible that the divisions which they undergo in gametogenesis are connected with the observed inheritance of characters.

Our conception of what occurs when a cross is made between two individuals may be illustrated by the diagram which forms fig. 2. Zygotes are here represented by squares and gametes by circles. The dominant and recessive characters are indicated by small plain and black rectangles. Each zygote must contain two and each gamete but one of these unit-characters. Zygotes such as the original parents which breed true to a given character are said to be homozygous for that character, and from their nature such homozygotes must produce identical gametes. Consequently when a cross is made only one kind of zygote can be formed, viz. that containing both the dominant and recessive unit-characters. When the germ-cells of such a heterozygote split to form gametes, these, as indicated in fig. 2, will be of two sorts containing the dominant and recessive characters respectively, and will be produced in equal numbers. If we are dealing with a hermaphrodite plant such as the pea the ovules will consist of one half bearing only the dominant character and one half bearing only the recessive character; and this will be true also of the pollen grains. Consequently each dominant ovule has an equal chance of being fertilized by a dominant or by a recessive pollen grain, and the dominant ovules must therefore give rise to equal numbers of dominant homozygous and of heterozygous plants. Similarly the recessive ovules must give rise to equal numbers of recessive homozygotes and of heterozygotes. Hence of the total offspring of such a plant one quarter will be pure dominants, one quarter recessives, and one half heterozygotes as indicated in fig. 2. Where one character is completely dominant over the other, heterozygotes will be indistinguishable in appearance from the homozygous dominant, and the F2 generation will be composed of three plants of the dominant form to each recessive. These are the proportions actually found by Mendel in the pea and by many other more recent observers in a number of plants and animals. The experimental facts are in accordance with the conception of unit-characters and their transmission from zygote to gamete in the way outlined above; and the numerical results of breeding experiments are to be regarded as proving that in the formation of gametes from the heterozygote the unit-characters are treated as unblending entities separating cleanly, or segregating, from one another. From this it follows that any gamete can carry but one of a pair of unit-characters and must therefore be pure for that character. The principle of the segregation of characters in gametogenesis with its natural corollary, the purity of the gametes, is the essential part of Mendel's discoveries. The quite distinct phenomenon of dominance observed by him in *Pisum* occurs in many other cases, but, as will appear below, by no means universal.

**Illustrations.**—Mendelian inheritance in its simplest form, i.e., for a single pair of characters, has already been shown to occur in many species of animals and plants, and for many very diverse characters. In some cases complete dominance of one of the pair of unit-characters occurs; in others the form of heterozygote is more or less intermediate. Fresh cases are continually being recorded and the following short list can but serve to give some idea of the variety of characters in which Mendelian inheritance has been demonstrated.

A. **Dominance nearly or quite complete.** (The dominant character is given first.)
- Tall and dwarf habit (pea, sweet pea).
- Round seed and wrinkled seed (pea).
- Long pollen and round pollen (sweet pea).
- Starch and sugar endosperm (maize).
- Hairiness and absence of hairs (stocks, *Lychnis*).
- Beardless and bearded condition (wheat).
- Prickliness and smoothness of fruits (*Datura*).
- Palm and fern leaf (*Primum*).
- Purple and red flowers (sweet pea, stocks, &c.).
- Fertility and sterility of anthers (sweet pea).
- Susceptibility and immunity to rust (wheat).
- Rose comb and single comb (fowls).
- Black and white plumage (Rosecomb bantams).
- Grey and black coat color (rabbits, mice).
- Bay and chestnut coat color (horses).
- Pigmentation and albinism (rabbits, rats, mice).
- Polled and horned condition (cattle).
- Short and long "Angora" coat (rabbits).
- Normal and walking habit (mice).
- Deformed hand with but two phalanges in digits and normal hand (man).
B. Absence of dominance, the heterozygote being more or less intermediate in form.

Black and white splashed plumage (Andalusian fowls). Lax and dense ears (wheat).

Six rowed and two rowed ears (barley).

Dominance.—The meaning of this phenomenon is at present obscure, and we can make no suggestion as to why it should be complete in one case, partial in another, and entirely absent in a third. When found it is as a rule definite and orderly, but there are cases known where irregularity exists. The extra toe characteristic of certain breeds of fowls, such as Dorkings, behaves generally as a dominant character, but in certain cases it has been ascertained that a fowl without an extra toe may yet carry the extra toe character. It is possible that in some cases dominance may be conditioned by the presence of certain other features, and certain crosses in sheep lend colour to the supposition that sex may be such a feature. A cross between the polled Suffolk and the horned Dorset breeds results in horned rams and polled ewes only, though in the F2 generation both sexes appear with and without horns. At present the simplest hypothesis which fits the facts is that horns are dominant in the male and recessive in the female. It is important not to confuse cases of apparent reversal of dominance such as the above with cases in which a given visible character may be the result of two entirely different causes. One white hen may give only colour chicks by a coloured cock, whilst the same cock with another white hen, indistinguishable in appearance from the former, will give only white chickens containing a few dark ticks. There is here no reversal of dominance, but, as has been abundantly proved by experiment, there are two entirely distinct classes of white fowls, of which one is dominant and the other recessive to colour.

The Presence and Absence Hypothesis.—Whether the phenomenon of dominance occur or not, the unit-characters exist in pairs, of which the members are seemingly interchangeable. In virtue of this behaviour the unit-characters forming such a pair have been termed allelomorphic to one another, and the question arises as to what is the nature of the relation between two allelomorphs. The fact that such cases of heredity as have been fully worked out can all be formulated in terms of allelomorphic pairs is suggestive, and has led to what may be called the "presence and absence" hypothesis. An allelomorphic pair represents the only two possible states of any given unit-character in its relation to the gamete, viz. its presence or its absence. When the unit-character is present the quality for which it stands is manifested in the zygote; when it is absent some other quality previously concealed is able to appear. When the unit-character for yellowness is present in a pea the seeds are yellow, when it is absent the seeds are green. If yellowness is an allelomorphic character underlying in all yellow seeds, but can only appear in the absence of the unit-character for yellowness, and greenness is allelomorphic to yellowness because it is the expression of absence of yellowness.

Dikhybridism.—The instances hitherto considered are all simple cases in which the individuals crossed differ only in one pair of unit-characters. Mendel himself worked out cases in which the parents differed in more than one allelomorphic pair, and he pointed out that the principles involved were capable of indefinite extension. The inheritance of the various allelomorphic pairs is to be regarded as entirely independent. For example, when two individuals AA and aa are crossed the composition of the F1 generation must be AA + aA + aa. If we suppose that the two parents differ also in the allelomorphic character for green ear and the green character is underlying in all yellow seeds, but can only appear in the absence of the unit-character for yellowness, and greenness is allelomorphic to yellowness because it is the expression of absence of yellowness.

The four types of comb referred to in the text are shown here. All the drawings were made from male birds. In the hens the combs are smaller. All four types of comb are liable to a certain amount of minor variation, and the walnut especially so. The presence of minute bristles on its posterior portion, however, serves at once to distinguish it from any other comb.

and green seed characters by B and b respectively, then the constitution of the F2 generation can be readily gathered from fig. 3. When the two allelomorphic pairs affect the same structure we may get the phenomenon of novelties appearing in F1 and F2. Certain breeds of fowls have a "rose" and others a "pea" comb (fig. 4). On crossing the two a "walnut" comb results, and the offspring of such walnuts bred together consist of 9 walnuts, 3 roses, 3 peas, and 1 single comb in every 16 birds. This case may be brought into line with the scheme in fig. 3 if we consider the allelomorphic pairs concerned to
be rose \((A)\) and absence of rose \((a)\), and pea \((B)\) and absence of pea \((b)\). The zygotic constitution of a rose is therefore \(AAbb\), and of a pea \(aaBB\). A zygote containing both rose and pea is a walnut; a zygote containing neither rose nor pea is a single. The peculiar feature of such a case lies in the fact that absence of rose and absence of pea are the same thing, i.e. single; and this is doubtless owing to the fact that the characters rose and pea both affect the same structure, the comb.

3. Cases exist in which the characters due to one allelomorphic pair can only become manifest in the presence of a particular member of the other pair. If in fig. 3 the characters due to \(B-b\) can only manifest themselves in the presence of \(A\), it is obvious that this can happen in twelve cases out of sixteen, but not in the remaining four, which are homozygous for \(aa\). An example of this is to be found in the inheritance of coat colour in rabbits, rats and mice where the allelomorphic pairs concerned are wild grey colour \((B)\) dominant to black \((b)\) and pigmentation \((A)\) dominant to albinism \((a)\). Certain albino \((aaBB)\) crossed with blacks \((AAbb)\) give only greys \((AaBb)\), and when these are bred together they give 9 greys, 3 blacks and 4 albinos. Of the 4 albinos 3 carry the grey character and 1 does not, but in the absence of the pigmentation factor \((A)\) this is not visible. The ratio \(9:3:4\) must be regarded as a \(9:3:3:1\) ratio, in which the last two terms are visibly indistinguishable owing to the impossibility of telling by the eye whether an albino carries the character for grey or not.

4. The appearance of a zygotic character may depend upon the coexistence in the zygote of two unit-characters belonging to different allelomorphic pairs. If in the scheme shown in fig. 3 the manifestation of a given character depends upon the simultaneous presence of \(A\) and \(B\), it is obvious that 9 of the 16 zygotes will present this character, whilst the remaining 7 will be without it. This is shown graphically in fig. 5, where the 9 squares have been shaded and the 7 left plain. The sweet pea offers an example of this phenomenon. White sweet peas breed true to whiteness, but when certain strains of whites are crossed the offspring are all coloured. In the next generation \((F_2)\) these \(F_1\) plants give rise to 9 coloured and 7 whites in every 16 plants. Colour here is a compound character whose manifestation depends upon the co-existence of two factors in the zygote, and each of the original parents was homozygous for one of the two factors necessary to the production of colour. The ratio \(9:7\) is in reality a \(9:3:3:1\) ratio in which, owing to special conditions, the zygotes represented by the last three terms are indistinguishable from one another by the eye.

The phenomena of dihybridism, as illustrated by the four examples given above, have been worked out in many other cases for plants and animals. Emphasis must be laid upon the fact that, although the unit-characters belonging to two pairs may react upon one another in the zygote and affect its character, their inheritance is yet entirely independent. Neither grey nor black can appear in the rabbit unless the pigmentation factor is also present; nevertheless, gametic segregation of this pair of characters takes place in the normal way among alblino rabbits, though its effects are never visible until a suitable cross is made. In cases of trihybridism the Mendelian ratio for the forms appearing in \(F_2\) is \(27:9:9:9:3:3:3:1\), i.e. \(27\) showing dominance of three characters, three groups of \(9\) each showing dominance of two characters, three groups of \(3\) each showing dominance of one character, and a single individual out of \(64\) which is homozygous for all three recessive characters. It is obvious that the system can be indefinitely extended to embrace any number of allelomorphic pairs.

**Reversion.**—Facts such as those just dealt with in connexion with certain cases of dihybridism throw an entirely new light upon the phenomenon known as reversion on crossing. This is now seen to consist in the meeting of factors which had in some way or other become separated in phylogeny. The albino rabbit when crossed with the black "reverts" to the wild grey colour, because each parent supplies one of the two factors upon which the manifestation of the wild colour depends. So also the wild purple sweet pea may come as a reversion on crossing two whites. In such cases the reversion appears in the \(F_1\) generation, because the two factors upon which it depends are the dominants of their respective allelomorphic pairs. Where the reversion depends upon the simultaneous absence of two characters it cannot appear until the \(F_2\) generation. When fowls with rose and pea combs are crossed the reversionary single comb characteristic of the wild Gallus bankiva first appears in the \(F_2\) generation.

**Gametic Coupling.**—In certain cases the distribution of characters in heredity is complicated by the fact that particular unit-characters tend to become associated or coupled together during gametogenesis. In no case have we yet a complete explanation of the phenomenon, but in view of the important bearing which these facts must eventually have on our ideas of the gametogenic process an illustration may be given. The case in which two white sweet peas gave a coloured on crossing has already been described, and it was seen that the production of colour was dependent upon the meeting of two factors, of which one was brought in by each parent. If the allelomorphic pairs be denoted by \(C-c\) and \(R-r\), then the zygotic constitution of the two parents must have been \(CCrr\) and \(ccRR\) respectively. The \(F_1\) plant may be either purple or red, two characters which form an allelomorphic pair in which the former is dominant, and which may be denoted by the letters \(B-b\). If \(B\) is brought in by one parent only the \(F_1\) plant will be heterozygous for all three allelomorphic pairs, and therefore of the constitution \(CcRrBb\). In the \(F_2\) generation the ratio of coloured to white must be \(9:7\), and of purple to red \(3:1\); and experiment has shown that this generation is composed on the average of 27 purples, 9 reds and 28 whites out of every 64 plants. The exact composition of such a family may be gathered from the accompanying table (fig. 6). So far the case is perfectly smooth, and it is only on the introduction of another character that the phenomenon of partial coupling is witnessed. Two kinds of pollen grain occur in the sweet pea. In some plants they are oblong in shape, whilst in others they are round, the latter condition being recessive to the former. If the original white parents were homozygous for long and round respectively the \(F_1\) purple must be heterozygous, and in the \(F_2\) generation, as experiment has shown, the ratio of longs to rounds for the whole family is \(3:1\). But among the purples there are about twelve longs to each round, the excess of longs here being balanced by the reds, where the proportion...
MENDELISM

Chromosomes and Unit-Characters.—Breeding experiments have established the conception of definite unit-characters existing in the cells of an organism: in the cell histology has demonstrated the existence of small definite bodies—the chromosomes. During gametogenesis there takes place what many histologists regard as a differentiating division of the chromosomes: at the same period occurs the segregation of the unit-characters. Is there a relation between the postulated unit-character and the visible chromosome, and if so what is this relation? The researches of E. B. Wilson and others have shown that in certain Hemiptera the character of sex is definitely associated with a particular chromosome. The males of Protoner possess thirteen chromosomes, and the qualitative division on gametogenesis results in the production of equal numbers of spermatozoa having six and seven chromosomes. The somatic number of chromosomes in the female is fourteen, and consequently all the mature ova have seven chromosomes. When a spermatozoon with seven chromosomes meets an ovum the resulting zygote has fourteen chromosomes and is a female; when a spermatozoon with six chromosomes meets an ovum the resulting zygote has thirteen chromosomes and is a male. In no other instance has any such definite relation been established, and in many cases at any rate it is certain that it could not be a simple one. The gametic number of chromosomes in wheat is eight, whereas the work of R. H. Biffen and others has shown that the number of unit-characters in this species is considerably greater. If therefore there exists a definite relation between the two it must be supposed that a chromosome can carry more than a single unit-character. It is not impossible that future work on gametic coupling may throw light upon the matter.

Heredity and Variation.—It has long been realized that the problems of heredity and variation are closely interwoven, and that whatever throws light upon the one may be expected to illuminate the other. Recent as has been the rise of the new science of genetics, however, it has not as yet been possible to refine and implement our views as to the nature of these phenomena. Heredity we now perceive to be a method of analysis, and the facts of heredity constitute a series of reactioes which enable us to argue towards the constitution of living matter. And essential to any method of analysis is the recognition of the individuality of the individual. Constitutional differences of a radical nature may be concealed beneath apparent identity of external form. Purple sweet peas from the same pod, indistinguishable in appearance and of identical ancestry, may yet be fundamentally different in their constitution. From one may come purples, reds and whites, from another only purples and reds, from another purples and whites alone, whilst a fourth will breed true to purple. Any method of investigation which fails to take account of the radical differences in constitution which may underlie external similarity must necessarily be doomed to failure. Conversely, we realize to-day that individuality in constitutional make-up may have an entirely different ancestral history. From the cross between two fowls with rose and pea combs, each of irreproachable pedigree for generations, come single combs in the second generation, and these singles are precisely similar in their behaviour to singles bred from strains of unblemished ancestry. In the ancestry of the one is to be found no single over a long series of years, in the ancestry of the other nothing but singles occurred. The creature of given constitution may often be built up in many ways, but once formed it will behave like others of the same constitution. The one sure test of the constitution of a living thing lies in the nature of the gametes which it carries, and it is the analysis of these gametes which forms the province of heredity.

The clear cut and definite mode of transmission of characters first revealed by Mendel leads inevitably to the conception of a definite and clear-cut basis for those characters. Upon this structural basis, the unit-character, are grounded certain of the phenomena now termed variation. Varieties exist as such in virtue of differing in one or more unit-characters from
MEDELSOHN, MOSES (1729-1786), Jewish philosopher, was born in Dessau in 1729. His father's name was Mendel, and he was later on surnamed Mendelssohn (=son of Mendel). He was the foremost Jewish figure of the 18th century, and to him is attributable the renaissance of the House of Israel. With this third Moses (the other two being the Biblical lawgiver and Moses Maimonides) a new era opens in the history of the Jewish people. Mendel Dessau was a poor scribe—a writer of scrolls—and his son Moses in his boyhood developed curvature of the spine. His early education was cared for by his father and by the local rabbi, David Fränkel. The latter, besides teaching him the Bible and Talmud, introduced to him the philosophy of Maimonides (q.v.). Fränkel received a call to Berlin in 1743. Not many months later a weakly lad knocked at one of the gates of Berlin. He was admitted after an altercation, and found a warm welcome at the hands of his former teacher. His life at this period was a struggle against crushing poverty, but his school of the Jewish refugee Pole, Zamosz, taught him mathematics, and a young Jewish physician was his tutor in Latin. He was, however, mainly self-taught. "He learned to spell and to philosophize at the same time" (Graetz). With his scanty earnings he bought a Latin copy of Locke's Essay concerning the Human Understanding, and mastered it with the aid of a Latin dictionary. He then made the acquaintance of Aaron Solomon Gumperz, who taught him the elements of French and English. In 1750 he was appointed by a wealthy silk-merchant, Isaac Bernhard, as teacher to his children. Mendelssohn soon won the confidence of Bernhard, who made the young student successively his book-keeper and his partner.

Gumperz or Hess rendered a conspicuous service to Mendelssohn and to the cause of enlightenment in 1754 by introducing him to Lessing. Just as the latter afterwards makes Nathan the Wise and Solomon a member of the chess-board, so did Lessing and Mendelssohn actually come together as lovers of the same game. The Berlin of the day—the day of Frederick the Great—was in a moral and intellectual ferment. Lessing was the great liberator of the German mind. He had already begun his work of toleration, for he had recently produced a drama (Die Juden, 1749), the motive of which was to prove that a Jew can be possessed of nobility of character. This notion was being generally ridiculed as untrue, when Lessing found in Mendelssohn the realization of his dream. Within a few months of the same age, the two became brothers in intellectual and artistic camaraderie. Mendelssohn owed his first introduction to the public to Lessing's admiration. The former had written in lucid German an attack on the national neglect of native philosophers (principally Leibnitz), and lent the manuscript to Lessing. Without consulting the author, Lessing published anonymously Mendelssohn's Philosophical Conversations (Philosophische Gespräche). The same year that appeared in Danzig an anonymous satire, Pope a Metaphysician (Pope ein Metaphysiker), the authorship of which soon transpired. It was the joint work of Lessing and Mendelssohn. From this time Mendelssohn's career was one of ever-increasing brilliance. He became (1756-1759) the leading spirit of Nicolai's important literary undertakings, the Bibliothek and the Literaturbriefe, and ran some risk (which Frederick's good nature obviated) by somewhat freely criticizing the poems of the king of Prussia. In 1752 he married. His wife was Frenet Gugenheim, who survived him by twenty-six years. In the year following his marriage Mendelssohn won the prize offered by the Berlin Academy for an essay on the application of mathematical proofs to metaphysics, although among the competitors were Abbt and Kant. In October 1763 the king granted Mendelssohn the privilege of Prince of Jew (Schulthei)—which assured his son and heir, and opened the way to a personal residence in Berlin.

As a result of his correspondence with Abbt, Mendelssohn resolved to write on the Immortality of the Soul. Materialistic views were at the time rampant and fashionable, and faith in immortality was at a low ebb. At this favourable juncture appeared the Phädn (1767). Modelled on Plato's dialogue

what is conventionally termed the type; and since these unit-characters must from their behaviour in transmission be regarded as discontinuous in their nature, it follows that the variation must be discontinuous also. A present tendency of thought is to regard the discontinuous variation or mutation as the material upon which natural selection works, and to consider that the process of evolution takes place by definite steps. Darwin's opposition to this view rested partly upon the idea that the discontinuous variation or sport would, from the rarity of its occurrence, be unable to maintain itself against the swamping effects of intercrossing with the normal form. Mendel's work has shown that this objection is not valid, and the precision of the mode of inheritance of the discontinuous variation leads us to inquire if the small or fluctuating variation can be shown to have an equally definite physiological basis before it is admitted to play any part in the production of species. Until this has been shown it is possible to consider the small variation as abstrusus in all evolutionary change, and to regard the fluctuating variation as the uninherit ed effect of environmental accident.

The Human Aspect.—In conclusion we may briefly allude to certain practical aspects of Mendel's discovery. Increased knowledge of heredity means increased power of control over the living thing, and as we come to understand more and more the architecture of the plant or animal we realize what can and what cannot be done towards modification or improvement. The experiments of Biffen on the cereals have demonstrated what may be done with our present knowledge in establishing new, stable, and more profitable varieties of wheat and barley, and it is impossible to doubt that as this knowledge becomes more widely disseminated it will lead to considerable improvements in the methods of breeding animals and plants.

It is not, however, in the economic field, important as this may be, that Mendel's discovery is likely to have most immediate practical application. The next light in which it will come to view himself and his fellow creatures. To-day we are almost entirely ignorant of the unit-characters that go to make the difference between one man and another. A few diseases, such as acanaptonia and congenital cataract, a digital malformation, and probably eye colour, are as yet the only cases in which inheritance has been shown to run upon Mendelian lines. The complexity of the subject must render investigation at once difficult and slow; but the little that we know to-day offers the hope of a great extension in our knowledge at no very distant time. If this hope is borne out, if it is shown that the qualities of man, his body and his intellect, his immunities and his diseases, even his virtues and vices, are dependent upon the ascertainable presence or absence of definite unit-characters whose mode of transmission follows fixed laws, and if also men decide that his life shall be ordered in the light of this knowledge, it would be that the social system will have to undergo considerable changes.

BIBLIOGRAPHY.—In the following short list are given the titles of papers dealing with experiments directly referred to the author. References to most of the literature will be found in (11), and a comprehensive account of the subject in (16).

of the same name, Mendelssohn's work possessed some of the charm of its Greek exemplar. What most impressed the German world was its beauty and lucidity of style—features to which Mendelssohn still owes his popularity as a writer. The Phädon was an immediate success, and besides being often reprinted in German was speedily translated into nearly all the European languages, including English. The author was hailed as the "German Plato," or the "German Socrates"; royal and other aristocratic friends showered attention on him, and it is no exaggeration to assert with Kayslering that "no stranger who came to Berlin failed to pay his personal respects to the German Socrates."

So far, Mendelssohn had devoted his talents to philosophy and criticism; now, however, an incident turned the current of his life in the direction of the cause of Judaism. Lavater was one of the most ardent admirers of Mendelssohn. He described him as "a companionable, brilliant soul, with piercing eyes, the body of an Aesop—a man of keen insight, exquisite taste and wide erudition... frank and open-hearted..." Lavater was fired with the ambition to convert his friend to Christianity. In the preface to a German translation of Bonnet's essay on Christian Evidences, Lavater publicly challenged Mendelssohn to refute Bonnet or if he could not then to "do what wisdom, the love of truth and honesty must bid him, what a Socrates would have done if he had read the book and found it unanswerable." This appeal produced a painful impression. Bonnet resented Lavater's action, but Mendelssohn was bound to reply, though opposed to religious controversy. As he put it: "Suppose there were living among my contemporaries a Confucius or a Solon, I could, according to the principles of my faith, love and admire the great man without falling into the ridiculous idea that I must convert a Solon or a Confucius."

Here we see the germs of Mendelssohn's Pragmatism, to use the now current term. He shared this with Lessing; in this case, at all events, it is probable that the latter was indebted to Mendelssohn. But before discussing this matter, we must follow out the consequences of Lavater's intrusion into Mendelssohn's affairs. The latter resolved to devote the rest of his life to the emancipation of the Jews. Among them secular studies had been neglected, and Mendelssohn saw that he could best remedy the defect by attacking it on the religious side. A great chapter in the history of culture is filled by the influence of translations of the Bible. Mendelssohn added a new section to this chapter by his German translation of the Pentateuch and other parts of the Bible. This work (1873) constituted Mendelssohn the Luther of the German Jews. From it, the Jews learned the German language; from it they imbibed culture; with it there was born a new desire for German nationality; as a result of its popularity was inaugurated a new system of Jewish education. Some of the conservatives among the Jews opposed these innovations, but the current of progress was too strong for them. Mendelssohn was the first great champion of Jewish emancipation in the 18th century. He it was who induced C. W. Dohm to publish in 1781 his epoch-making work, On the Civil Amelioration of the Condition of the Jews, a memorial which played a great part in the triumph of tolerance. Mendelssohn himself published a German translation of the Vindiciae judaorum by Menasseh ben Israel. The excitement caused by these proceedings led Mendelssohn to publish his most important contribution to the problems connected with the position of Judaism in relation to the general life.

This work was the Jerusalem (1783; Eng. trans. 1838 and 1852). It is a forcible plea for freedom of conscience. Kant described it as "an irreproachable book." Its basic idea is that the state had no right to interfere with the religion of its citizens. As Kant put it, this was "the proclamation of a great reform, which, however, will be slow in manifestation and in progress, and which will affect not only your people but others as well." Mendelssohn asserted the pragmatic principle of the possible plurality of truths: that just as various nations need different constitutions—to one monarchy, to another a republic, may be the most congenial to the national genius—so individuals may need different religions. The test of religion is its effect on conduct. This is the moral of Lessing's Nathan the Wise, the hero of which is undoubtedly Mendelssohn. The parable of the three rings is the epitome of the pragmatic position. One direct result of this pragmatism was unexpected. Having been taught that there is no absolutely true religion, Mendelssohn's own descendants—a brilliant circle, of which the musician Felix was the most noted—left the Synagogue for the Church. But despite this, Mendelssohn's theory was found to be a strengthening bond in Judaism. For he maintained that Judaism was less a "divine need, than a revealed life." In the first part of the 19th century, the criticism of Jewish dogmas and traditions was associated with a firm adhesion to the older Jewish mode of living. Reason was applied to beliefs, the historic consciousness to life. Modern reform in Judaism is parting to some extent from this conception, but it still holds good even among the liberals.

Of Mendelssohn's remaining years it must suffice to say that he progressed in fame numbering among his friends more and more of the greatest men of the age. His Morgenstunden appeared in 1783, and he died as the result of a cold contracted while carrying to his publishers in 1786 the manuscript of a vindication of his friend Lessing, who had predeceased him by five years.

Mendelssohn had six children. His sons were: Joseph (founder of the Mendelssohn banking house, and a friend and benefactor of Alexander Humboldt), whose son Alexander (d. 1871) was the last Jewish descendant of the philosopher; Abraham (who married Leah Bartholdy and was the father of Fanny Hensel and J. L. Felix Mendelssohn-Bartholdy); and Nathan (a mechanical engineer of considerable repute). His daughters were Dorothea, Recha and Henriette, all brilliantly gifted women.

Of Mendelssohn's grandsons, Felix (1809–1847), German composer, grandson of Moses Mendelssohn (q.v.), was born in Hamburg on the 3rd of February 1809. In consequence of the troubles caused by the French occupation of Hamburg, Abraham Mendelssohn, his father, migrated in 1811 to Berlin, where his grandmother Fromet, then in the twenty-fifth year of her widowhood, received the whole family into her house, No. 7 Neue Promenade. Here Felix and his sister Fanny received their first instruction in music from their mother, under whose care they progressed so rapidly that their exceptional talent soon became apparent. Their next teacher was Madame Bigot, who, for a time, was engaged to Mrs. Fromet. On their return to Berlin they took lessons in thoroughbass and composition from Zelter, in pianoforte-playing from Ludwig Berger, and in violin-playing from Henning—the care of their general education being entrusted to the father of the novelist Paul Heyse.

Felix first played in public on the 24th of October 1818, taking the pianoforte part in a trio by Weölli. On the 11th of April 1819 he entered the Berlin Singakademie as an alto, and in the following year began to compose with extraordinary rapidity. His earliest dated work is a cantata, In rührend feierlichen Tönen, completed on the 13th of January 1820. During that year alone he produced nearly sixty movements, including songs, pianoforte sonatas, a trio for pianoforte, violin and violoncello, a sonata for violin and pianoforte, pieces for the organ, and even a little dramatic piece in three scenes. In 1821 he wrote five symphonies for stringed instruments, each in three movements; motets for four voices, an
opera, in one act, called Soldatenleben; another, called Die beiden Pädagogen; part of a third, called Die wundernden Comödianten; and an immense quantity of other music of different kinds, all showing the precocity of his genius. The original autograph copies of these early productions are preserved in the Berlin Library, where they form part of a collection which fills forty-four large volumes, all written with infinite neatness, and for the most part carefully dated—a sufficient proof that the methodical habits which distinguished his later life were formed in early childhood.

In 1821 Mendelssohn paid his first visit to Goethe, with whom he spent sixteen days at Weimar, in company with Zelter. From this year also dates his first acquaintance with Weber; who was then in Berlin superintending the production of Der Freischiitz, which was only in course of introduction, at Cassel, to another of the greatest of his contemporaries, Ludwig Spohr. During this year his pen was even more prolific, producing, among other works, an opera, in three acts, entitled Die beiden Nffen, oder der Onkel aus Boston, and a pianoforte concerto, which he played in public at a concert given by Frau Anna Milder.

It had long been a custom with the Mendelssohn family to give musical performances on alternate Sunday mornings in their dining-room, with a small orchestra, which Felix always conducted, even when he was not tall enough to be seen without standing upon a stool. For each of these occasions he produced some new work—playing the pianoforte pieces himself, or entrusting them to his sister Cecilia, who sang, and his brother Paul played the violoncello. In this way Die beiden Nffen was first privately performed, on the fifteenth anniversary of his birthday, the 3rd of February 1824. Between the 3rd and the 31st of March in this year he composed his fine symphony in C minor, now known as Op. 10, and soon afterwards the quartet in B minor, Op. 3, and the (posthumous) pianoforte sextet, Op. 110. In this year also began his lifelong friendship with Moscheles, who, when asked to receive him as a pupil, said, "If he wishes to take a hint from me, as to anything new to him, he can easily do so; but he stands in no need of lessons."

In 1825 Abraham Mendelssohn took Felix to Paris, where among other musicians then resident in the French capital he met the two most Popular dramatic composers of the age, Rossini and Meyerbeer, and lived on terms of intimacy with Hummel, Kalkbrenner, Rode, Baillot, Herz, and many other artists of European celebrity. On this occasion also he made his first acquaintance with Cherubini, who, though he rarely praised any one, expressed a high opinion of his talent, and recommended him to write a Kyrie, for five voices, with full orchestral accompaniments, which he himself described as "exceeding in thickness" anything he had attempted. From letters written at this period we learn that Felix's estimate of the French school of music was far from flattering; but he formed some friendships in Paris, which were renewed on later occasions. He returned to Berlin with his father in May 1825, taking with him the most Popular dramatic composer of the age, the late grand-duke of Sachsen-Coburg, and interrupting his journey at Weimar, he procured the consent of paying a second visit to Goethe, to whom he dedicated his quartet in B minor. On reaching home he must have worked with greater zeal than ever; for on the 10th of August in this same year he completed an opera, in two acts, called Die Hochzeit des Camacho, a work of considerable importance.

No ordinary boy could have escaped uninjured from the snares attendant upon such a life as that which Mendelssohn now lived. Notwithstanding his overwhelming passion for music, his general education had been so well cared for that he was able to hold his own, in the society of his seniors, with the grace of an accomplished man of the world. He was already recognized as a leading spirit by the artists with whom he associated, and the talents which were so soon acknowledged in his position and genius. Notwithstanding the temptations to egoism by which he was surrounded would have rendered most clever students intolerable. But the natural amiability of his disposition, and the healthy influence of his happy home-life, counteracted all tendencies towards self-assertion.

Soon after his return from Paris, Abraham Mendelssohn removed from his mother's residence to No. 3 Leipziger Strasse, a roomy, old-fashioned house, containing an excellent music-room, and in the grounds adjoining a "Gartenhaus" capable of accommodating several hundred persons at the Sunday performances. In the autumn of the following year this "garden-house" witnessed a memorable private performance of the work by means of which the greatness of Mendelssohn's genius was first revealed to the outer world—the overture to Shakespeare's Midsummer Night's Dream. The finished score of this famous composition is dated "Berlin, August 6, 1826."—It was only when he next composed for the stage that he so in later works does he exhibit more originality of thought, more freshness of conception, or more perfect mastery over the details of technical construction, than in this delightful inspiration. The overture was first publicly performed at Stettin, in February 1827, under the direction of the young composer, who was at once accepted as the leader of a new and highly characteristic manifestation of the spirit of progress. Henceforth we must speak of him, not as a student, but as a mature and experienced artist.

Meanwhile Camacho's Wedding had been submitted to Spontini, with a view to its production at the opera. The libretto, founded upon an episode in the history of Don Quixote, was written by Klingemann, and Mendelssohn threw himself into the spirit of the romance with a keen perception of its pathos, humour. The work was put into rehearsal soon after the composer's return from Stettin, produced on the 20th of April 1827, and received with great apparent enthusiasm; but a cabal was formed against it, and it never reached a second performance. The critics abused it mercilessly; yet it exhibits merits of a very high order. The solemn passage for the trombones, which heralds the first appearance of the knight of La Mancha, is conceived in a spirit of reverent appreciation of the idea of Cervantes, which would have done honour to a composer of lifelong experience.

Mendelssohn was annoyed at this injustice, and some time elapsed before his mind recovered its usual bright tone; but he continued to work diligently. Among other serious undertakings, he turned a new study of the choruses of the church works of Sebastian Bach, then unknown to the public; and, in spite of Zelter's opposition, he succeeded, in 1829, in inducing the Berlin Singakademie to give a public performance of the Passion according to St Matthew, under his direction, with a chorus of between three and four hundred voices. The scheme succeeded beyond his warmest hopes, and proved the means of restoring to the world great compositions which had never been heard since the death of Bach. But the obstructive party were offended; and at this period Mendelssohn was far from popular among the musicians of Berlin.

In April 1829 Mendelssohn paid his first visit to London. His reception was enthusiastic. He made his first appearance at the English and French cabinet, and at the Philharmonic Society's concerts—then held in the Argyll Rooms—on the 25th of May, conducting his symphony in C minor from the pianoforte, to which he was led by John Cramer. On the 30th he played Weber's Concertstück, from memory, a proceeding at that time extremely unusual. At a concert given by Drouet, on the 24th of June, he played Beethoven's pianoforte concerto in E flat, which had never before been heard in the country; and the overture to A Midsummer Night's Dream was also, for the first time, presented to a London audience. On returning home from the concert, Attwood, then organist of St Paul's Cathedral, left the score of the overture in a hackney coach, whereupon Mendelssohn wrote out another, from memory, without an error. At another concert he played, with Moscheles, his still unpublished concerto in E, for two pianofortes and
orchestra. After the close of the London season he started with Klingemann on a tour through Scotland, where he was inspired with the first idea of his overture to The Isles of Fingal, returned to London in the end of November. Except for an accident to his knee, which lamed him for some time, his visit was highly successful and laid the foundation of many friendships and prosperous negotiations.

The visit to England formed the first division of a great scheme of travel which his father wished him to extend to all the most important art centres in Europe. After refusing the offer of a professorship at Berlin, he started again, in May 1830, for Italy, pausing on his way at Weimar, where he spent a fortnight with Goethe, and reaching Rome, after many pleasant interruptions, on the 1st of November. No excitement prevented him from devoting a certain time every day to composition; but he lost no opportunity of studying either the countless treasures which form the chief glory of the great city or the manners and customs of modern Romans. He attended, with insatiable curiosity, the services in the Sistine Chapel; and his keen power of observation enabled him to throw much interesting light upon them. His letters on this subject, however, lose much of their value through his incapacity to comprehend the close relation existing between the music of Palestrina and his contemporaries and the ritual of the Roman Church. His Lutheran education kept him in ignorance even of the first principles of ordinary chanting; and it is amusing to find him describing as enormities peculiar to the papal choir customs familiar to every village singer in England, and as closely connected with the structure of the "Anglican chant," as with that of "Gregorian music." Still, though he could not agree in all points with Baini, the greatest ecclesiastical musician then living, he shared his admiration for the Improperia, the Missere, and the cantus planus of the Lamentations and the Exultet, the musical beauty of which he could understand, apart from their ritual significance.

In passing through Munich on his return in October 1831, he composed and played his pianoforte concerto in G minor, and accepted a commission (never fulfilled) to compose an opera for the Munich theatre. Pausing for a time at Stuttgart, Frankfort and Düsseldorf he arrived in Paris in December, and passed four pleasant months in the renewal of acquaintances formed in 1825, and in close intercourse with Liszt and Chopin. On the 19th of February 1832 the overture to A Midsummer Night's Dream was played at the conservatoire, and many of his other compositions were brought before the public; but he did not escape disappointments with regard to some of them, especially the Reformation symphony, and the visit was brought to a premature close in March by an attack of cholera, from which, however, he rapidly recovered.

On the 23rd of April 1832 he was again in London, where he twice played his G minor concerto at the Philharmonic concerts, gave a performance on the organ at St Paul's, and published his first book of Lieder and Songs. He returned to Berlin in July, and during the winter he gave public performances of his Reformation symphony, his concerto in G minor, and his Walpurgisnacht. In the following spring he paid a third visit to London for the purpose of conducting his Italian symphony, which was played for the first time, by the Philharmonic Society, on the 15th of May 1833. On the 26th of the same month he conducted the performances at the Lower Rhine festival at Düsseldorf with such brilliant effect that he was at once offered, and accepted, the appointment of general music-director to the town, an office which included the management of the music in the principal churches, at the theatre, and at the rooms of two musical associations.

Before entering upon his new duties, Mendelssohn paid a fourth visit to London, with his father, returning to Düsseldorf on the 27th of September 1833. His influence produced an excellent effect upon the church music and in the concert-room; but his relations with the management of the theatre were not altogether pleasant; and it was probably this circumstance which first led him to forsake the cultivation of the opera for that of sacred music. At Düsseldorf he first designed his famous oratorio St Paul, in response to an application from the Cícilien-Verein at Frankfort, composed his overture to Die schöne Melusine, and planned some other works of importance. He liked his appointment, and would probably have retained it much longer had he not been invited to undertake the permanent direction of the Gewandhaus concerts at Leipzig, and thus raised to the highest position attainable in the German musical world. To this new sphere of labour he removed in August 1835, opening the first concert at the Gewandhaus, on the 4th of October, with his overture Die Meeresstille, a work possessing great attractions, though by no means on a level with the Midsummer Night's Dream, The Isles of Fingal, or Melusine.

Mendelssohn's reception in Leipzig was most enthusiastic; and under their new director the Gewandhaus concerts prospered exceedingly. Meanwhile St Paul steadily progressed, and was first produced, with triumphant success, at the Lower Rhine festival at Düsseldorf, on the 22nd of May 1836. On the 3rd of October it was first sung in English, at Liverpool, under the direction of Sir George Smart; and on the 16th of March 1837 Mendelssohn again directed it at Leipzig.

The next great event in Mendelssohn's life was his happy marriage, on the 28th of March 1837, to Cecile Charlotte Sophie Jeanrenaud. The honeymoon was scarcely over before he was again summoned to England to conduct St Paul, at the Birmingham festival, on the 20th of September. During this visit he played on the organ at St Paul's and at Christ Church, Newgate Street, with an effect which exercised a lasting influence upon English organists. It was here also that he first contemplated the production of his second oratorio, Elijah.

Passing over the composition of the Lobgesang in 1840, a sixth visit to England in the same year, and his inauguration of a scheme for the erection of a monument to Sebastian Bach, we find Mendelssohn in 1841 recalled to Berlin by the king of Prussia, to fill the vacant position of music-director. Though his appointment resulted in the production of Antigone, Odysseus Colonus, Athalie, the incidental music to the Midsummer Night's Dream, and other great works, it proved an endless source of vexation, and certainly helped to shorten the composer's life. In 1842 he came to England for the seventh time, accompanied by his wife, conducted his Scotch symphony at the Philharmonic, again played the organ at St Peter's, Cornhill, and Christ Church, Newgate Street, and was received with honour by the queen and the prince consort. He did not, however, permit his new engagements to interfere with the direction of the Gewandhaus concerts; and in 1843 he founded in Leipzig the great conservatoire which soon became the best musical college in Europe, opening it on the 3rd of April in the buildings of the Gewandhaus. In 1844 he conducted six of the Philharmonic concerts in London, producing his new Midsummer Night's Dream music, and playing Beethoven's pianoforte concerto in G with extraordinary effect. He returned to his duties at Berlin in September, but succeeded in persuading the king to free him from his most onerous engagements.

After a brief residence in Frankfurt, Mendelssohn returned to Leipzig in September 1845, resuming his old duties at the Gewandhaus, and teaching regularly in the conservatoire. Here he remained, with little interruption, during the winter—introducing his friend Jenny Lind, then at the height of her popularity, to the critical frequenter of the Gewandhaus, and steadily working at Elijah, the first performance of which he conducted at the Birmingham festival, on the 26th of August 1846. The reception of this great work was enthusiastic. Unhappily, the excitement attendant upon its production, added to the irritating effect of the worries at Berlin, made a serious inroad upon the composer's health. On his return to Leipzig he worked on as usual, but it was clear that his health was seriously impaired. In 1847 he visited England for the tenth and last time, to conduct four performances of Elijah at Exeter Hall, on the 16th, 23rd, 28th and 30th of April, one at Manchester on the 20th, and one at Birmingham on the 27th.
MENDES

This article has the unique value of being the record of an eminent musical scholar who was an actual pupil of Mendelssohn. No change of reputation can alter the value of such a record of a man whom even his contemporaries knew to be greater than his fame. Mendelssohn's unbounded enthusiasm fitted him for triumph in a period of revolution; he died, most unhappily, when his own powers, like Handel's at the same age, were being wasted on pseudo-classical forms; the new art was not yet in full blossom. In the name and memory of Mendelssohn's first attempt to be assassinated. That of the most tender and gentle

"Romantic" pioneer Schumann soon followed; but, as being more difficult to explain away, and more embarrassingly to irreverence and retreats. Nonetheless, Mendelssohn's reputation, except as the composer of a few inexpitably beautiful and original orchestral pieces, has vanished and been replaced by a pure fiction known as the "Mendelssohn tradition" of orchestral performance.

The first marks were made by Wagner on his experiences of English orchestral playing, remarks which, though not very good-natured, do not bear the full construction popularly imputed to them. If Beethoven had come and conducted in England, careless players would have been met by references to the "Beethoven tradition"; and, if Wagner had shared Mendelssohn's reluctance to putting on record remarks likely to wound individual, professional and national sensibilities, it might not have been impossible that reproaches against slipshod and mechanical playing might nowadays be met by references to the "Wagner tradition," for Wagner also found himself compelled to concentrate his care on the main items in the overcrowded English orchestral programmes, to the detriment of the rest.

Mendelssohn's influence on the early career of Joachim is, next to his work in the rediscovery of Bach, his greatest bequest to later musical history. Those many profound and sincere admirers of Mendelssohn who could do so, turned to Joachim to learn how his contemporaries had seen and heard the music of the Eighteenth Century.

MENDÈS, CATULLE (1841-1900), French poet and man of letters, of Jewish extraction, was born at Bordeaux on the 2nd of March, 1841. He was educated in Paris, and, after attaining the dignity of Bachelor of Arts, he went to the Sorbonne. He was a professor of music, and a poet, and a man of letters, and a man of letters.

Mendelssohn's title to a place among the great composers of the century is incontestable. His style, though differing little in technical arrangement from that of his classical predecessors, is characterized by a vein of melody peculiarly his own, and easily distinguishable by those who have studied his works, not only from the genuine effusions of contemporary writers, but from the most successful of the servile imitations with which, even during his lifetime, the music-shops were deluged. In less judicious hands the rigid symmetry of his phrase might, perhaps, have pallied upon the ear; but under his skilful management it serves only to impart an additional charm to thoughts which derive their chief beauty from the evident spontaneity of their conception. In this, as in all other matters of a purely technical character, he regarded the accepted laws of art as the medium by which he might most certainly attain the ends dictated by the inspiration of his genius. Though caring nothing for rules, except as means for producing a good effect, he scarcely ever violated them, and was never weary of impressing their value upon the minds of his pupils. His method of counterpoint was modelled in close accordance with that practised by Sebastian Bach. This he used in combination with an elastic development of the sonata-form, similar to that engrafted by Beethoven upon the lines laid down by Haydn. The principles involved in this arrangement were really conservative; yet they enabled him, at the very outset of his career, to invent a new style no less original than that of Schubert or Weber, and no less remarkable as the embodiment of canons already consecrated by classical authority than as a special manifestation of individual genius. It is thus that Mendelssohn stands before us as at the same time a champion of conservatism and an apostle of progress; and it is chiefly by virtue of these two apparently incongruous though really compatible phases of his artistic character that his influence and example prevailed, for so many years, to hold in check the violence of reactionariness which injudicious partisanship afterwards fanned into revolutionary fury.

Concerning Mendelssohn's private character there have never been two opinions. As a man of the world he was more than ordinarily accomplished—brilliant in conversation, and in his letters overflowing with sparkling humor and ready pleasantry, loyal and unselfish in the more serious business of life, and never weary of working for the general good. As a friend he was unvaryingly kind, sympathetic and true. His earnestness as a Christian needs no stronger testimony than that afforded by his own delineation of the character of St Paul; but it is not too much to say that his heart and life were pure as those of a little child.

(W. S. R.)
On the 6th of February 1909, early in the morning, his dead body was discovered in the railway tunnel of Saint Germain. He had left Paris by the midnight train on the 7th, and it is supposed that, thinking he had arrived at the station, he had opened the door of his compartment while still in the tunnel.

**MENDICANCY** (from Lat. mendicans, in a condition of beggary, a word of unknown origin), a state or condition of being a beggar, the practice of obtaining a livelihood by asking alms. The word "mendicant," also found in the French form "mendiant," appears to have come into use through the begging friars.

**MENDICANT MOVEMENT AND ORDERS.** The facts concerning the rise of the Orders of Mendicant Friars are related in the articles on the several orders (Franciscans, Dominicans, Carmelites, Augustinian Hermits), and in that on Monasticism (§ 11), where the difference between friars and monks is explained. The purpose of this article is to characterize the movement as a whole, and to indicate the circumstances that produced it. The most striking phenomenon in connexion with the beginnings of the mendicant orders is the rapidity with which the movement spread. Within a generation of the death of the two great founders, Dominic (1221) and Francis (1226), their institutions had spread so widely through Europe that they could be numbered by tens of thousands. In all the great cities of Western Europe friaries were established, and in the universities theological chairs were held by Dominicans and Franciscans. And when at the middle of the century the other great mendicant orders of Carmelites and Austin Friars, and also Servites (q.v.) arose their propagation showed that the possibilities of the mendicant movement had not been exhausted by the Dominicans and Franciscans. Lesser mendicant orders sprang up in all directions—Gasquet mentions half a dozen such that found their way into England (English Monastic Life, p. 241)—in such numbers that the Council of Lyons in 1274 found it necessary to suppress all except the orders already named. Moreover, besides the various orders of friars, there were the lay Tertiarys that arose and spread far and wide in connexion with the Franciscans and other mendicants, and the similar institute of the Humiliati (see TERTIARIES). These facts clearly show that the Mendicant Movement responded to widely spread and deeply felt needs of the time. The new word expression not only the Franciscan and Dominican orders within the Church, but also in a number of more or less heretical and revolutionary religious sects. There was this in common among the Cathari, Waldenses, Albigenses and other heretical bodies that overran so many parts of Western Europe in the second half of the 12th century and the beginning of the 13th, that they all inveighed against the wealth of the clergy, and preached the practice of austere poverty and a return to the simple life of Christ and the Apostles. Thus the sectaries no less than the Mendicant orders bear witness to the existence of spiritual needs in Western Christendom, which the Mendicant orders went a long way towards satisfying. Probably the most crying need was that of priests to minister to the great city populations, at that time growing up with such rapidity, especially in Italy. During the 10th, 11th and 12th centuries the Church had been organized on the lines of the prevailing feudal system—the bishops and abbots were feudal barons, and the effects of the system were felt throughout the ranks of the lower clergy. The social and economic condition of the towns, but on the greater landlords; and when the centre of gravity began to move, first of all in Italy, to the towns, and crowded populations began to be massed together in them, the parochial systems broke down under the weight of the new conditions, and the people were in a state of spiritual and moral no less than physical destitution. So, when the friars came and established themselves in the poorest localities of the towns, and brought religion to the destitute and the outcasts of society, assimilating themselves to the conditions of life of those among whom they worked, they supplied a need with which the parochial clergy were unable to cope.

The friars responded not only to the new needs of the age, but to its new ideas—religious, intellectual, social, artistic. It was a period of religious revival, and of reaction against abuses that followed in the wake of the feudal system; and this religious movement was informed by a new mysticism—a mysticism that fixed its attention mainly on the humanity of Christ and found its practical expression in the imitation of His life. A new intellectual wave was breaking over Western Europe, symbolized by the university and the scholastic movements; and a new spirit of democratic freedom was making itself felt in the growing commercial towns of Italy and Germany. There is no need to labour the point that the Mendicants responded to all these needs and interpreted them within the pale of Catholic Christianity, for the fact lies upon the surface of history. But a few words are necessary on the central idea from which the Mendicants received their name—the idea of poverty. This was St Francis's root idea, and there is no doubt—that it was borrowed from him by St Dominic and the other Mendicant founders. St Francis did not intend that begging and alms should be the normal means of sustenance for his friars; on the contrary, he intended them to live by the work of their hands, and only to have recourse to begging when they could not earn their livelihood by work. But in the absence of work, he provided for the friars to be supported by public ministrations, and the communities grew larger, it became increasingly difficult for them to support themselves by personal work; and so the beggery came to play a greater rôle than had been contemplated by St Francis. But his idea certainly was that his friars should not only practise the utmost personal poverty and simplicity in their life, but that they should have the minimum of possessions—no lands, no funded property, no fixed sources of income. The maintaining of this ideal has proved unworkable in practice. In the Dominican Order and the others that started as mendicant it has been mitigated or even abrogated. Among the Franciscans themselves it has been the occasion of endless strife, and has been kept alive only by dint of successive reforms and fresh starts, each successful for a time, but doomed always, sooner or later, to yield to the inexorable logic of facts. The Capuchins (q.v.) have made the most permanently successful effort to maintain St Francis's ideal; but even among them mitigations have had to be admitted. In spite, however, of all mitigations of the life, the friars have presented to the world an object lesson in evangelical poverty by the poorness and simplicity of their lives and surroundings.

On the subject-matter of this article the best thing in English is the Introductory Essay by the Capuchin Fr. Cuthbert on "The Spirit and Genius of the Franciscan Friars," in The Friars and how they came to England (1903); see also the earlier chapters of Emil Gebhard's Italie mystique (1899).

**MENDIP HILLS,** a range in the north of Somersetshire, England. Using the name in its widest application, the eastern boundary of the range may be taken to be formed by the upper valleys of the rivers Frome and Brue, and the depression between them. The range extends from these northward with a major axis of about 23 m., while the outliers of Waving Down and Bleadon Hill continue it towards the shore of the Bristol Channel. The range is generally about 6 m. in width, and its total area about 130 sq. m. Its southwestern face descends to the low "moors" or marshes drained by the Avon, and the streams, the small towns of Axbridge, Cheddar and Wells lying at the foot of the hills. Towards the north-east its limits are less clearly defined, for high ground, intersected by narrow vales, extends as far as the valley of the Avon. A depression, followed by the road between Radstock and Wells, strikes across the range about its centre; the principal elevations lie west of this, and to the area thus defined the name of the Mendips is sometimes restricted. The summit of the hills is a gently swelling plateau, which reaches its extreme height in the north—1068 ft. The Mendips consist principally of Carboniferous Limestone. Fine cliffs and scarps occur on the flanks of the plateau, as in the gorge of Cheddar, and there is a wonderful series of caverns, the result of water action. The surface of the plateau is often broken by deep holes
MENDOZA, A. H. DE—MENDOZA, P. G. DE

("swallets") into which streams flow. Some of the caves, such as those at Cheddar, are easy of access, and attract many visitors owing to the beauty of the stalactitic formations; others, of greater extent and grandeur, have only been explored, or partly explored, with great difficulty. Some caves have yielded large quantities of animal remains (hyaenas, bears and others) together with traces of prehistoric human occupation. Among such Wookey Hole, where the river Axe issues from the foot of a cliff, may be mentioned. Lead was worked among the Mendips at a very early period. Some of the Roman workings, especially in the neighbourhood of Charterhouse-on-Mendip, have yielded pigs of lead inscribed with the names of emperors of the 1st and 2nd centuries A.D., together with an abundance of smaller objects.

MENDOZA, ANTONIO HURTADO DE (1503?–1644), Spanish dramatist, was born about the end of the 16th century in the province of Asturias, became page to the count of Saldaña (son of the duke of Lerma), and was recognized as a rising poet by Cervantes in the Viaje del Parnaso (1614). He rose rapidly into favour under Philip IV., who appointed him private secretary, commissioned from him comedias palaciegas for the royal theatre at Aranjuez, and in 1623 conferred on him the orders of Santiago and Calatrava. Most of his contemporaries and rivals paid court to "el discreto de palacio," and Mendoza seems to have lived on the friendliest terms with all his brother-dramatists except Ruiz de Alarcón. He is said to have been involved in the fall of Olivares, and died unexpectedly at Saragossa on the 19th of September 1644. Only one of his plays, Querer por sólo querer, was published with his consent; it is included in a volume (1623) containing his semi-official account of the performances at Aranjuez in 1622. The best edition of Mendoza's plays and verses bears the title of Obras teatrales y cínicas, divinas y humanas (1728). Much of his work does not rise above the level of graceful and accomplished verse; but that he had higher qualities is shown by El Marido hace mujer, a brilliant comedy of manners, which forms the chief source of Molière's École des maris.

The Fiéis que se hizô en Aranjuez and Querer por sólo querer were translated into English by Sir Richard Fanshawe, afterwards ambassador at Madrid, in a posthumous volume published in 1671.

MENDOZA, DIEGO HURTADO DE (1503–1575), Spanish novelist, poet, diplomatist and historian, a younger son of the count of Tendillas, governor of Granada, was born in that city in 1503. The celebrated marquis of Santillana was his great-grandfather. On leaving the university of Salamanca, Mendoza abandoned his intention of taking orders, served under Charles V. in Italy, and attended lectures at the universities of Bologna, Padua and Rome. In 1537 he was sent to England to arrange a marriage between Henry VIII. and the duchess of Milan, as well as a marriage between Prince Louis of Portugal and Mary Tudor. Despite the failure of his mission, he preserved the confidence of the emperor, and in 1539 was appointed ambassador at Venice; there he patronized the Aldi, procured copies of the Greek manuscripts belonging to Cardinal Bessarion, and acquired other rare codices from the monastery of Mount Athos. The first edition of Josephus was printed (1544) from the texts in Mendoza's collection. He acted for some time as military governor of Siena, represented Spain diplomatically at the council of Trent, and in 1547 was nominated special plenipotentiary at Rome, where he remained till 1554. He was never a favourite with Philip II., and a quarrel with a courtier resulted in his banishment from court (June 1568). The remaining years of his life, which were spent in Granada, he devoted to the study of Arabic, to poetry, and to his history of the Moorish insurrection of 1568–1570. He died in 1575.

His Guerra de Granada was published at Lisbon by Luis Tribaldos de Toledo in 1627; the delay was doubtless due to Mendoza's severe criticism of contemporaries who survived him. In some passages the author deliberately imitates Sallust and Tacitus; his style is, on the whole, vivid and trenchant, his information is exact, and in critical insight he is not inferior to Mariana. The attribution to Mendoza of Lazarillo de Tormes is rejected by all competent scholars, but that he excelled in picareseque malice is proved by his indecorous verses written in the old Castilian metres and in the more elaborate measures imported from Italy. Mendoza is believed to be the author of the letters to Feliciano de Silva and to Captain Salazar, published by Antonio Paz y Melia in Sales Españolas (Madrid, 1900). See A. Salnán y Alonso, D. Diego Hurtado de Mendoza, apuntes biográfico-criticos (Granada, 1930); Calendar of Letters and Papers of the Spanish Monarchs, vol. 2 (London, 1933). C. Gueux, Essai sur l'origine des fonds grec de l'Escorial (Paris, 1830); R. Fouche-Delbosc, "Etude sur la Guerra de Granada " in the Revue hispánique (Paris, 1894), vol. i.

MENDOZA, PEDRO GONZALEZ DE (1428–1495), Spanish cardinal and statesman, was the fourth son of Íñigo Lopez de Mendoza, marquess of Santillana, and duke of Infantado. He was born at Guadalajara in New Castile, the chief lordship of his family, on the 3rd of May 1428. The house of Mendoza claimed to descend from the lords of Llodio in Alava, and to have been settled in Old Castile, in the 11th century. One chief of the house had been greatly distinguished at the battle of the Navas de Tolosa in 1212. Another had been Admiral of Castile in the reign of Alphonso the Wise. Peter the Cruel had endowed them with the lordships of Hita and Buítrago. The greatness of the Mendoza was completed by Pedro Gonzalez, who sacrificed his life to save King John I. at the battle of Aljubarrota in 1385. The cardinal's father, the marquis of Santillana—

to use the title he bore for the greater part of his life—was a poet, and was conspicuous during the troubled reign of John II. Loyalty to the Crown was the traditional and prevailing policy of the family. Pedro Gonzalez, the future cardinal, was sent into the Church mainly because he was a younger son and that he might be handsomely provided for. He had no vocation, and was an example of the worldly, political and martial prelates of the 15th century. In 1452 at the age of twenty-four, he was chosen by the king John II. to be bishop of Calahorra, but did not receive the pope's bull till 1454. As bishop of Calahorra he was also señor, or civil and military ruler, of the town and its dependent district. In his secular capacity he led the levies of Calahorra in the civil wars of the reign of Henry IV. He fought for the king at the second battle of Olmedo on the 20th of August 1467, and was wounded in the arm. During these years he became attached to Doña Mencia de Lemus, a Portuguese lady-in-waiting of the queen. She bore him two sons, Rodrigo, who was once selected to be the husband of Lucrezia Borgia, and Diego, who was the grandfather of the princess of Eboli of the reign of Philip II. (see Pérez, Antonio.) By another lady of a Valladolid family he had a third son who afterwards emigrated to France. In 1468 he became bishop of Siguenza. In 1473 he was created cardinal, was promoted to the archbishopric of Seville and named chancellor of Castile. During the last years of the reign of King Henry IV. he was the partisans of the Princess Isabel, afterwards queen. He fought for her at the battle of Toro on the 1st of March 1476; had a prominent part in placing her on the throne; and served her indefatigably in her efforts to suppress the disorderly nobles of Castile. In 1482 he became archbishop of Toledo. During the conquest of Granada he contributed largely to the maintenance of the army. On the 2nd of January 1492 he occupied the town in the name of the Catholic sovereigns. Though his life was worldly, and though he was more soldier and statesman than priest, the "Great Cardinal," as he was commonly called, did not neglect his duty as a bishop. He used his influence with the queen and also at Rome to arrange a settlement of the disputes between the Spanish sovereigns and the papacy. Though he maintained a splendid household as archbishop of Toledo, and provided handsomely for his children, he devoted part of his revenue to charity, and with part he endowed the college of Santa Cruz at Valladolid. His health broke down at the close of 1493. Queen Isabella visited and nursed him on his deathbed. It is said that he recommended her to choose as his successor the Franciscan Jimenez de Cisneros.
MENDEZ—MENEDEMUS

a man who had no likeness to himself save in political faculty and devotion to the authority of the Crown. He died at Guadalajara on the 13th of January 1495.

The life of the cardinal, by Salazar de Mendoza, Cronica del gran cardinal Don Pedro Gonzalez de Mendoza (Toledo, 1625), is discursive and garrulous but valuable. See also Prescott, History of Ferdinand and Isabella.

MENDEZ, a province of western Argentina, bounded N. by San Juan, E. by San Luis and the territory of La Pampa, S. by the territories of La Pampa and Neuquen, and W. by the republic of Chile. Area, 56,502 sq. m.; pop. (1895), 116,136; (1904, estimate), 159,780. The Andes form the western boundary, and a considerable part of the territory is covered by the great Cordillera, its foothills and flanking ranges. The eastern part is an arid, sandy, level plain, with extensive saline basins, having no vegetation other than coarse grasses and thickets of low, spiny mimoses and "chañar" (Gourhiaca decorcianis). The fertile, populated districts of the province border on the Cordillera, particularly in the north where numerous streams from the snow-clad summits supply water for irrigation. The secondary ranges in this part of Mendoza are the Sierra de Mendoza, which encloses the Uspallata Valley, and the Sierra del Tunuyán, which encloses a number of populous valleys drained by the Tunuyán river and its tributaries. One of the largest of these is the Yuco Valley. Farther south the country becomes more arid and sparsely populated, and subdued tribes of Indians for a long time prevented its exploration. In this region the Sierra de Payén and Sierra del Nevado (otherwise known as the Sierra Quero Matro Pello) extend in a north-easterly direction. With the exception of the Rio Grande in the south-west part of the province, which forms the principal source of the Colorado, all the rivers of the province flow easterly and southerly into the great saline depression of western Argentina, which includes a great part of Mendoza, San Luis and La Pampa. The Andean streams rise in the higher snow-clad elevations, but their waters become impregnated with saline matter soon after reaching the plain, and are eventually lost in the saline marshes and lagoons of the southern Mendoza and La Pampa. These Andean rivers are the Mendoza, Tunuyán, Diamante and Atuel, with their numerous tributaries, all of which discharge into the sluggish river which flows from the Huanacache lagoons, on the San Juan frontier, southward to the marshes and lagoons of La Pampa. The upper part of this brackish, swampy stream is called the Desaguadero, and the lower the Salado. It forms the eastern boundary line of the province down to the 36th parallel. With the exception of the elevated districts of the Andes, the climate of Mendoza is hot and dry. On the plains the rainfall is insignificant, but on the slopes of the Cordillera rains are frequent and winter cold is severe. Agriculture is the principal occupation where irrigation can be used, the province having a high reputation for its raisins and wines. Alfalfa is an important product, being grown for fattening the cattle driven through the province to the Chilean markets. The mineral resources of the province are said to be good, but receive little attention. Petroleum is found in the vicinity of San Rafael on the Diamante river, and it is claimed that coal exists in the same region. Although Mendoza was settled by Spanish colonists from Chile as far back as 1559, its development has been hindered by its isolated position. This isolation was broken in 1884 by the completion of the Argentine Great Western railway to the provincial capital. Since then a railway has been built northward to San Juan, and another line was in 1908 under construction through the Andes to connect with the Chilean railway system. In addition to Mendoza, the capital of the province, the principal towns (hardly more than villages) are Guaymallen, Maipú, San Martin, Lujan and San Rafael. The provinces of Mendoza, San Juan and San Luis, which were settled from Chile and were for a long time governed from Santiago, were at first called the province of Cuyo, and are still spoken of as the "Cuyo provinces."

MENDOZA, a city of Argentina, capital of Mendoza province, 632 m. by rail W.N.W. of Buenos Aires. Pop. (1904, estimate), 32,000. It stands on a plain near the foot of a secondary Andean range called the Sierra de los Paramillos, at an elevation of 2320 ft. The surrounding district is arid, but has been irrigated and is covered with gardens, orchards and cultivated fields. The city is about 15 m. N. of the Mendoza, or Lujan river, whose waters are utilized for irrigation and for the requirements of the city by means of a channel which leaves the main river a little above the town of Lujan and runs to the Tuluncay river and the lagoons of Huanacache. This channel is called El Zanjón, and is believed to have been opened by Guaymallen, the chief of the Guarapes who inhabited this district at the time of the Spanish conquest, but it is more probably natural. The city is laid out in a regular manner with broad well-paved streets and numerous public squares. The Zanjón and another stream called the Guaymallen traverse the city, and the principal streets have water flowing through them and are shaded by poplars. Because of earthquake risks, the public buildings are neither costly nor imposing. The private residences are commonly of one storey, built with wooden frames filled in with adobe. The climate is hot, dry and enervating, notwithstanding the elevation and the proximity of the Andes. The surrounding districts produce fruit, vegetables, alfalfa and cereals. The vineyard industry is prominent, and raisins and wine are exported. The position on the main route across the Andes into Chile, by way of the Uspallata or Cumbre pass (highest point 12,870 ft.), has given the city commercial importance. It has railway connexion with the principal cities of the republic, including the ports of Rosario, Buenos Aires and Bahia Blanca, and also with the capital of San Juan.

Mendoza was founded by Captain Pedro del Castillo, who had been sent from Santiago across the Andes in 1559 by Garcia Hurtado de Mendoza, the governor of Chile, to conquer and annex the territory extending N.E. to Tucuman. The city was named after Mendoza. It was the capital of the province of Cuyo, and belonged to Chile down to 1776, when the province was transferred to the newly created viceroyalty of La Plata. It was the headquarters of General San Martin while he was organizing an army for the liberation of Chile, and greatly assisted him with men and money. Under republican administration Mendoza suffered much from revolutions. Moreover, on the 20th of March 1861 the city was destroyed by an earthquake and a fire which followed. Not a building was left standing, and the loss of life was estimated at 10,000 to 12,000. The French geologist Bravard, who had predicted the catastrophe, was one of its victims. The poplars in the streets, together with some species of fruit-trees, were first planted in Mendoza by a Spaniard, Juan Cobos, in 1809, who thus became one of its greatest benefactors.

MENEDEMUS, Greek philosopher, and founder of the Eretrian school of thought, was born at Eretria about 350 and died between 278 and 273 B.C. Though of noble birth, he worked as builder and tentmaker until he was sent with a military expedition to Megara, where, according to Diogenes Laertius, he was killed in battle. It is said of him that, to scatter his attention, he was once put asleep on the lap of a woman. It is more likely that he heard one of Plato's followers, insomuch as Plato died when he was only four years old, if the above dates are correct. At Megara he formed a life-long friendship with Asclepiades, with whom he toiled in the night that he might study philosophy by day. He was subsequently a pupil first of Stilpo and then of Phaedo of Elis, whose school he transferred to Eretria, by which name it was afterwards known. In addition to his philosophical work, he took a leading part in the political affairs of his city from the time of the Diadochi until his death, and obtained a remission of the tribute to Demetrius. His friendship with Antigonus Gonatas seems to have roused suspicion as to his loyalty, and he sought safety first in the temple of Amphiaraus at Oropus, and later with Antigonus, at whose court he is said to have died of grief. Other accounts say that he starved himself to death on failing to induce Antigonus to free his native city. His philosophical views are known only in part. Athenaeus quotes Epicrates as stating that he was a Platonist, but other accounts credit

MENDOZA—MENEDEMUS

127
him with having preferred Stilpo to Plato. Diogenes Laërtius (ii. 134 and 135) says that he declined to identify the Good with the Useful, and that he denied the value of the negative proposition on the ground that affirmation alone can express truth. He probably meant to imply that qualities have no existence apart from the subject to which they belong. In ethics we learn from Plutarch (De virt. mor. 2) and from Cicero (Acad. ii. 42) that he regarded Virtue as one, by whatever name it be called, and maintained that it is intellectual. Cicero's evidence is the less valuable in that he always assumed that Menedemus was a follower of the Megarians. Diogenes says that he left no writings, and the Eretrian school disappeared after a short and unobtrusive existence.

Beside the ancient sources quoted above, see H. Mallett, Histoire de l'école de Mégare et des écoles d'Elis et d'Érétre (1845). Also the articles MEGARIAN SCHOOL; PHAEDO; STILPO.

**MENELAUS**. In Greek legend, son of Atreus (or Pleisthenes), king of Sparta, brother of Agamemnon and husband of Helen. He was one of the Greeks who entered Troy concealed in the wooden horse (Virgil, Aeneid, ii. 264) and recovered his wife at the sack of the city. On the voyage homeward his fleet was scattered off Cape Malea by a storm, which drove him to Egypt. After eight years' wandering in the east, he landed on the island of Pharos, where Proteus revealed to him the means of appeasing the gods and securing his return. He reached Sparta on the day on which Orestes was holding the funeral feast over Aegisthus and Clytaemnestra. After a long and happy life in Lacedaemon, Menelaus, as the son-in-law of Zeus, did not die but was translated to Elysium (Homer, Odyssey, iii. iv.). His grave and that of Helen were shown at Therapnae, where he was worshipped as a god (Pausanias iii. 10. 9). He was represented in works of art as carrying off the body of the dead Patroclus or lifting up his hand to slay Helen.

**MENELEK II.** (Sahala Mirem), emperor of Abyssinia, officially negus negusti (king of kings) of Ethiopia (1844— ), son of Haell Melicoth, king of Shoa, was born in 1844, and claimed to be a direct descendant of Solomon by the queen of Sheba. On the death of his father in 1855 he was kept a prisoner at Gondar by Kassai, the governor, who had seized the throne under the title of Theodore III. But having succeeded in effecting his escape he was acknowledged king of Shoa, and at once attacked the usurper. These campaigns were unsuccessful, and he turned his arms to the west, east and south, and annexed much territory to his kingdom, still, however, maintaining his divine right to the crown of Ethiopia. After the death of Theodore in 1888 he continued to struggle against his successor, the emperor Johannes (better known to Europeans as King John of Abyssinia). Being again unsuccessful, he resolved to await a more propitious occasion; so, acknowledging the supremacy of Johannes, in 1886 he married his daughter Zeodita (b. 1876) to the emperor's son, the Ras Area; he was thereupon declared heir to the empire, and on his side acknowledged the Ras Area as his successor. Ras Area died in May 1886, and the Ras Menelek immediately prepared against the dervishes at the battle of Gallabat (Matemba) on the 10th of March 1889. The succession now lay between the late emperor's natural son, the Ras Mangasha, and Menelek, but the latter was elected by a large majority on the 4th of November, and consecrated shortly afterwards. Menelek had married in 1885 Taftu (b. 1854) a princess of Tigre, a lady who had been married four times previously and who exercised considerable influence. Menelek's clemency to Mangasha, whom he compelled to submit and then made viceroy of Tigre, was ill repaid by a long series of revolts. In 1889, at the time when he was claiming the throne against Mangasha, Menelek signed at Ucciali a treaty with Italy acknowledging Italian claims to the Asmara district. Finding, however, that according to the Italian view of one of its articles the treaty placed his empire under Italian domination, Menelek denounced it; and after defeating the Italians at Amba-Alagi, he compelled them to capitulate at Adowa in February 1896, and a treaty was signed recognizing the absolute independence of Abyssinia. His French sympathies were shown in a reported official offer of treasure towards payment of the indemnity at the close of the Franco-Prussian War, and in February 1897 he concluded a commercial treaty with France on very favourable terms. He also gave assistance to French officers who sought to reach the upper Nile from Abyssinia, there to join forces with the Marchand Mission; and Abyssinian armies were sent Nilewards. A British mission under Sir Rennell Rodd in May 1897, however, was cordially received, and Menelek agreed to a settlement of the Somali boundaries, to keep open to British commerce the caravan route between Zalla and Harrar, and to prevent the transit of munitions of war to the Mahdists, whom he proclaimed enemies of Abyssinia. In the following year the Sudan was reconquered by an Anglo-Egyptian army and thereafter cordial relations between Menelek and the British authorities were established. In 1889 and subsequent years, Menelek sent forces to co-operate with the British troops engaged against the Somali mullah, Mahommeh Abdullah. Menelek had in 1898 crushed a rebellion by Ras Mangasha (who died in 1906) and he directed his efforts henceforth to the consolidation of his authority, and in a certain degree, to the opening up of his country to western civilization. He had granted in 1894 a concession for the building of a railway to his capital from the French port of Jibuti, but, alarmed by a claim made by France in 1902 to the control of the line in Abyssinian territory, he stopped for four years the extension of the railway beyond Dire Dawa. When in 1906 France, Great Britain and Italy came to an agreement on the subject, Menelek officially reiterates his full sovereign rights over the whole of his empire. In May 1909 the emperor's grandson Liy Yashu, or Jeauss, then a lad of thirteen, was married to Romanie (b. 1902), granddaughter of the negus Johannes. Two days later Yashu was publicly proclaimed as Adis Ababa as Menelek's successor. At that time the emperor was seriously ill and as his ill-health continued, a council of regency—from which the emperor was excluded—was formed in March 1910. (See also ABBYSSINIA.)

**MENENIUS LANYATUS, AGrippa,** Roman patrician and statesman, consul 703 B.C. On the occasion of the first secession of the people to the Sacred Mount, Agrippa, who was known to be a man of moderate views, was one of the commissioners empowered by the senate to treat with the seceders. On this occasion he recited the well-known fable of the belly and the members.

Liv. ii. 16, 32, 33; Dion. Halic. v. 44-47; vi. 49-88, 96; Val. Max. iv. 4, 2.

**MENES,** the name of the founder of the 1st Dynasty of historical kings of Egypt. He appears at the head of the lists not only in Herodotus and Manetho, but also in the native Turin Papyrus of Kings and the lists of Abydos, while the list
of Sakkara begins with the sixth king of the 1st Dynasty, a fact which may throw some doubt on the supposed foundation of Memphis by Menes. Until recently he was looked upon as semi-mythical, but the discovery of the tombs of many kings of the 1st Dynasty including probably that of Menes himself, as well as an abundance of remains of still earlier ages in Egypt has given him a personality. He was probably ruler of Upper Egypt and conquered the separate kingdom of Lower Egypt.

**MENGS, ANTONY RAPHAEL** (1728-1779), German painter, was born in 1728 at Aussig in Bohemia, but his father, Ismael Mengs, a Danish painter, established himself finally at Dresden, whence in 1741 he took his son to Rome. The appointment of Mengs in 1746 as first painter to the elector of Saxony did not prevent his spending much time in Rome, where he had married in 1748, and acquired the Protestant faith, and where he became in 1754 director of the Vatican school of painting, nor did this hinder him on two occasions from obeying the call of Charles III. of Spain to Madrid. There Mengs produced some of his best work, and specially the ceiling of the banqueting-hall, the subject of which was the Triumph of Trajan and the Temple of Glory. After the completion of this work in 1777, Mengs returned to Rome, and there he died, two years later, in poor circumstances, leaving twenty children, seven of whom were pensioned by the king of Spain. Besides numerous paintings in the Madrid gallery, the Ascension at Dresden, Persicus and Andromeda at St. Petersburg, and the ceiling of the Villa Albani must be mentioned among his chief works. In England, the duke of Northumberland possesses a Holy Family, and the colleges of All Souls and Magdalen, at Oxford, have also pieces by his hand. In his writings, in Spanish, Italian and German, Mengs has put forth his eclectic theory of art, which treats of perfection as attainable by a well-schemed combination of diverse excellences—Greek design, with the expression of Raphael, the chiaroscuro of Correggio, and the colour of Titian. His intimacy with Winckelmann—who constantly wrote at his direction—has enhanced his historical importance, for he formed no scholars, and the critic must now concur in Goethe's judgment of Mengs in Winckelmann und sein Jahrhundert; he must deplore that so much learning should have been allied to a total want of initiative and poverty of invention, and embodied with a strained and artificial mannerism.

See Opere di Antonio Raffaello Mengs (Parma, 1780); Mengs Werke, überseits v. G. F. Frange (1780); Zeitschrift für bildende Kunst (1848-1873); Biographisches Lexicon (Mengs, 1780); Woermann, Ismael und Raphael Mengs (Leipzig, 1893).

**MENGTSZE, a city in the S.E. of the province of Yunnan, China. Pop. about 12,000. It was selected by the French convention of 1868 as the seat of the overland trade between Tongking and Yunnan, and opened two years later. It is beautifully situated in the centre of a valley basin on a plateau 3,500 ft. above sea-level. The country round is fertile and well cultivated, and the place must have been one of considerable wealth before the Taiping rebellion, as the ruins of many fine temples attest. A considerable overland trade has sprung up since the opening of Mengtsze. Of the import trade Hong-Kong supplied 86%, and of the export trade 70% Cochin-China, Tongking and Annam claim the remainder. Tin (68%) and opium (27%) are the principal exports, and textiles (71%), mustard cottons, and tobacco (4%) are the chief imports. On the Tongking side this trade follows the Red River route as far as Manhao, which is distant from Mengtsze about 40 m., though the navigation of the river is difficult. From Manhao the transit is by coolies or pack animals. Concessions have been obtained by the French government to build a line of railway from the Tongking frontier at the town of Laokay via Mengtsze to Yunnan-fu. The climate is equable and healthy.

**MENHADEN**, economically one of the most important fishes of the United States, known by a great number of local names, "menhaden" and "mossbunker" being those most generally in use. The Indians and white settlers used it as a manure, and the name is Narragansett for "fertilizer." Its scientific name is Clupea (or Alosa) menhaden and Brevoortia tyrannus. It is allied to the European species of shad and pilchard, and, like the latter, approaches the coast in immense shoals, which are found throughout the year in some part of the littoral waters between Maine and Florida, the northern shoals retiring into deeper water or to more southern latitudes with the approach of cold weather. The average size of the menhaden is about 12 in. It is too bony and oily for a table-fish, but is used as bait for cod and mackerel. A large fleet is engaged in the fishery; and a great number of factories extract the oil for tanning and currying, and for adulterating other more expensive oils, and manufacture the refuse into a valuable guano.

**MENIAL**, that which belongs to household or domestic service, hence, particularly, a domestic servant. The idea of such service being derogatory has made the term one of contempt. The word is derived from an obsolete menie or mene, the company of household servants or retainers; a Scottish form is mensie. The origin is to be found in the O.Fr. messie, popular Lat. mansionata, from mansio, mansion, from which comes Fr. maison, house.

**MÉNIER, EMILE JUSTIN** (1826-1881), French manufacturer and politician, was born at Paris in 1826. In 1853, on the death of his father, Antoine Brutus Ménié, he became proprietor of a large drug factory, founded in 1815 by the latter at Saint Denis, Paris, and in 1825 at Noisiel-sur-Marne. Antoine Brutus Ménié had also manufactured chocolate in a small way, but Emile Justin from the first devoted himself specially to chocolate. He purchased cocoa-growing estates in Nicaragua and beet-fields in France, erected a sugar-mill, and equipped himself in other ways for the production of chocolate on a large scale. In 1864 he sold his interest in the drug-manufacturing business, and thenceforth confined himself to chocolate, building up an immense trade. Ménié was a keen politician, and from 1876 till his death had a seat in the French Chamber, his general views being strongly Republican, while he consistently opposed protection. He was the author of several works on fiscal and economic questions, notably L'Impôt sur le capital (1872), La Réforme fiscale (1872), Économie rurale (1875), L'Avenir économique (1875-1878), Atlas de la production de la richesse (1878). He died at Noisiel-sur-Marne in 1881, his sons succeeding to the business.

**MÉNIÈRE'S DISEASE,** a form of auditory vertigo, first described by a French physician, Emile Antoine Méniére, in 1861. It usually attacks persons of middle age whose hearing has been previously normal. A. Politzer gives the following as the principal causes: intense heat and exposure to the sun, rheumatism, influenza, venereal diseases, anaemia and leukæmia. The disease presents itself in various forms, but the most usual is the apoplectiform, due to haemorrhage into the labyrinth, followed by more or less complete deafness in either or both ears. The attack usually sets in with dizziness, noises in the ears, nausea, vomiting and staggering gait, and the patient may suddenly fall down with loss of consciousness. The seizures are usually paroxysmal, occurring at irregular intervals of days or weeks. Between the attacks the equilibrium may be disturbed, there being marked nystagmus and unsteadiness of gait. The attacks of vertigo tend to become less frequent and may entirely pass away, but the deafness may remain permanent. The treatment is directed towards relieving the troublesome head symptoms by the application of cold combs as the principal causes: intense heat and exposure to the sun, rheumatism, influenza, venereal diseases, anaemia and leukæmia. The disease presents itself in various forms, but the most usual is the apoplectiform, due to haemorrhage into the labyrinth, followed by more or less complete deafness in either or both ears. **MINEM (Flemish Meenen), a town of Belgium in the province of West Flanders situated on the Lys 7 m. S. of Courtrai. Pop. (1904), 19,377. It manufactures linen and flannel, and in the neighbourhood are extensive tobacco plantations. It was first
fortified in 1578, and in 1685 Vauban made it one of the strongest places on the French frontier, but the fortifications were razed in 1748 by the treaty of Aix-la-Chapelle.

MENINGITIS (from Gr. μηνιγή, a membrane), a term in medicine applied to inflammation affecting the membranes of the brain (cerebral meningitis) or spinal cord (spinal meningitis) or both.

Tubercular cerebral meningitis (or Acute Hydrocephalus) is a disease due to inflammation of the meninges of the brain produced by the presence of a tubercle bacillus. This disease is most common in children under ten years of age, but may affect adults. The tubercular constitution is an important factor in this malady. In numerous cases it is manifestly connected with bad hygienic conditions, with insufficient or improper feeding, or with over exercise of the mental powers, all of which will doubtless more readily exert their influence where an inherited liability exists, and the same may be said regarding its occasional occurrence as one of the after-consequences of certain of the diseases of childhood, especially measles and whooping-cough.

The disease is not a specific one, and symptoms vary in each of its stages. The premonitory symptoms are mostly such as relate to the general nutrition. A falling off in flesh and failure of strength are often observed for a considerable time before the character of the disease is evident. The first symptom is that a child, becomes listless and easily fatigued, loses appetite, and is restless at night. There is headache after exertion, and the child becomes unusually irritable. These symptoms may persist during many weeks; but on the other hand such premonitory indications may never appear, and the disease be developed to all appearance suddenly.

The onset is in most instances marked by the occurrence of vomiting, often severe, but sometimes only slight, and there is in general obstipation. The child is in no wise prostrated, and remains absent, or reappears at a later period. Headache is one of the most constant of the earlier symptoms, and is generally intolerable to the patient. He sleeps little, or not at all, with the patient to scream, with a peculiar and characteristic cry. There is great intolerance of light and sound, and general nervous sensitiveness. Fever is present to a greater or less extent, the temperature ranging from 100° to 103° F.; yet the pulse is more quickened in proportion, being on the contrary rather slow, but exhibiting a tendency to irregularity, and liable to become rapid on slight exertion. The breathing, too, is somewhat irregular. Symmetry of character, constituting the stage of excitement, continue for a period varying from one to two weeks, when they are succeeded by the stage of depression. There is now a marked change in the symptoms, which is apt to lead to the belief that a favorable crisis has taken place. The patient wakes early, or sleeps and inclines to sleep, but it will be found on careful watching that this quietness is but a condition of apathy or partial stupor into which the child has sunk. The vomiting has ceased, and there is less fever; the pulse is slower, and shows a still greater tendency to irregularity than before, with the least motion of markedly unequal character, being rapid and shallow at one time, and long drawn out and sinking away at another. There is manifestly little suffering, although the peculiar cry may still be uttered, and, and talk to those about, and the duration of a varied fever upon the pillow, or picking at the bedclothes or at his face with his fingers. He does not ask for food, but readily swallows what is offered. The countenance is pale, but is apt to flush up suddenly for a short time, and then to become flushed alternately with being dilated or unequal, and scarcely responding to light. There may be double vision, or partial or complete blindness. Squinting is common in this stage, and there may also be dropping of an eyelid, due to paralytic effect of the part, and one or more limbs may be likewise paralysed.

To this succeeds the third or final stage, in which certain of the former symptoms recur, while others become intensified. There is generally a return of the fever, the temperature rising sometimes very high. The pulse becomes feeble, rapid, and exceedingly irregular, as is also the case with the breathing. Coma is profound; but yet the patient may still be able to swallow sufficient nourishment, though not food. Convulsions may occur, but they are rarely severe. After a severe paralytic fit, more or less extensive, affects portions of the body or groups of muscles. The pupils are now widely dilated, and there is generally complete blindness and often deafness. In this condition the patient's strength undergoes rapid decline, and the body becomes markedly emaciated. Death takes place, whether rapid or more gradually from exhaustion. Shortly before death it is not uncommon for the patient, who, it may be for many days previously, lay in a state of profound stupor, to awake, ask for food, and show signs of reviving; but this is so transitory, and the patient is often somewhat, but in general death takes place within three weeks from the onset of the symptoms. The disease may be said to be almost invariably fatal, yet cases presenting all the principal symptoms occasionally recover.

Much may be done in the way of prevention of this disease, and, in its earlier stages, even in the way of cure. It is most important to recognize the symptoms when they arise. The maintenance of the patient's strength by light nourishment and the use of sedatives to compose the nervous system are the measures most likely to be attended with success. Bromide, combined with iodide of potassium, is the medicinal agent of most value for this purpose. Should convulsions occur, they are best treated by chloral or chloroform.

In what is known as suppurative, or simple acute meningitis (non-tubercular), the disease arises from various causes, and the symptoms are similar to those described above.

In posterior-basic meningitis, inflammation of the membranes investing the posterior basic spinal cord, the chief symptoms are fever, with severe pain in the back or loins shooting downwards into the limbs (which are the seat of frequent painful involuntary startling), accompanied with a feeling of tightness round the body.

The local symptoms bear reference to the portion of the cord to which the symptoms are involved. Thus when the inflammation is located in the cervical portion the muscles of the arms and chest are spasmodically contracted, and there may be difficulty of swallowing or breathing, or embarrassed heart's action, while the observers regard these for a longer period, the cases of cerebral spinal fever; and Still, William Hunter and George Nuttall have isolated an organism similar to the diplococcus intracellularis, while Henry Koplik in New York found cases of typical posterior-basic meningitis due to diplococcus intracellularis.

The treatment is directed to allaying the pain and inflammatory action by opiates. Ergot is recommended by many physicians. The patient should have perfect rest in the recumbent, or better sitting position, and the larger members should be elevated, so that the patient may feel that he is not suffering from the effects of gravity, and may, of course, be of use, while attention to the functions of the bladder and bowels, and to the condition of the skin with the view of preventing sores, is all-important.

Cerebro-spinal fever or epidemic cerebro-spinal meningitis, popularly called "spotted fever," is an infectious disease occurring sporadically or in epidemics, and due to the diplococcus intracellularis discovered by Weichselbaum in 1887. This disease was not recognized until the 19th century. It was first described at Geneva in 1805 and small outbreaks followed in Paris (1814), Metz and Genoa (1815), and Westphalia (1822), but in the United States there was a widespread epidemic, including New England and spreading as far as Kentucky and Ohio. Fresh outbreaks in Europe took place between 1837 and 1850. In 1853 it prevailed in the south of France chiefly amongst troops in garrison, and fresh outbreaks continued throughout France in 1856 with epidemics in Algiers, Italy and Sicily. In Great Britain it first showed itself in the Irish workhouses in 1846, where it was known as "the black death" or "malignant-purpuric fever." After 1866 except for sporadic cases it disappeared from Great Britain, but small outbreaks took place in 1885 to 1900 in Dublin. In 1905 there was an extensive epidemic in France, followed by an outbreak in Scotland in 1906, and in Scotland and Ireland in 1907-1908. The registrar-general's returns for 1907 give 1018 deaths in Scotland due to the disease, of which 711 were at Glasgow and 148 at Edinburgh. In the same year Belfast was visited by a severe epidemic, 495 deaths out of the total death-rate of 631 taking place in that district.
The mode of infection is obscure, but the organism is thought to gain access to the circulation through the mucous membrane of the nose and conjunctiva, as the organism has been isolated from the mucous membrane of the nose, not only of those suffering from the disease, but from healthy persons who have in common with cases. Cerebro-spinal fever has an undoubted tendency to follow bad sanitary conditions and to prevail in damp, sunless houses. It is a disease of temperate climates, and the outbreaks usually occur in the spring of the year. The victims are usually children; young adults and Koplik states that few recoveries take place in children under two years of age.

The onset of symptoms is sudden, as contrasted with tuberculous meningitis, in which the onset is gradual. The attack comes on sharply with headache, vomiting, and fever, and during the first few days the condition rapidly develops, leading to coma and death in a few days. If the disease is not promptly recognized and treated, the patient soon localizes itself in the back of the neck and occiput, and may thence radiate down the spine, limbs and abdomen. The pain is soon followed by a characteristic symptom, namely retraction of the eyeballs, known as "Menippus." It is an early symptom of the disease; the eyes are drawn up, the pupils are dilated, and the limbs drawn up, and muscular spasms may take place. There is general hyperaesthesia, the slightest contact producing pain. More or less fever is present, but the temperature is not characteristic. The headache continues with restlessness and delirium supervene, or there may be long periods when the patient is comatose. Twitching of the limbs and general convulsions may occur and facial paralysis is frequent. Paralysis of the optic nerve may cause a loss of vision, while dilations and contractions of the pupil are common as in other varieties of meningitis.

Some of the most striking symptoms are the rashes. These usually occur about the fourth day of illness and vary widely in character, including erythema, petechiae, hemorhages, and purpuric spots. The rashes have usually in relation to the gravity of the disease, but severe cutaneous haemorrhages usually indicate a severe form of illness. Should the patient survive the first shock of the attack serious complications may arise; the eyes may be attacked, the muscles and joints may become inflamed, while the parts may take place leading to detachment of the retina. More frequent even is disease of the auditory apparatus, and purulent otitis media or disease of the labyrinth may lead to permanent deafness. In both cases the swelling may take place in joints which are painful, red and swollen as in acute rheumatism.

Certain forms of the disease are rapidly fatal, these are known as the fulminating type, and death may take place within 12 to 24 hours. These cases are usually identified by the presence of purpuric spots, which appear between the seventh and eighth day, but many cases drag on for weeks with rapid and progressive emaciation, and recovery is slow. The mortality has varied in different epidemics. Hirsch's tables of forty-one epidemics give a mortality of from 75 to 80%.

During 1907, 623 cases of cerebro-spinal fever were notified in all states of the Union, and the deaths numbered 495. During that year the disease was made notifiable in 48 Irish urban and 55 rural districts. The disease was notified in 218 urban and 25 rural districts in all states of the Union (New York) the mortality reached 38.6%.

The changes found after death from cerebro-spinal fever are an acute inflammation of the pia-arachnoid membrane both of the brain and spinal cord with effusion and focal areas of subarachnoid spaces. With such rapidity that the effusion becomes purulent it has been found purulent in a case where death took place within five hours from the apparent onset. The operation of lumbar puncture or puncture of the spinal canal between the transverse processes of the vertebrae and beneath the skin. Usually the serum of the spinal fluid is a clear serous fluid containing serum globulins and leucocytes. The introduction of serum therapy the future is full of hope. In the epidemic in New York (1905) the serum of Flexner and Joubert was used, and the most striking results were seen in young patients, the mortality being from 25 to 75%, and in the army at Camp Hoffman against 90% without. Like other serum treatments, to get the best results the serum must be administered early in the disease. Of 221 patients injected during the first week of illness the mortality was 72.5%, but after 12 days the mortality was only 30%. Dr. Ivy McKenzie and Dr. W. B. Martin of Glasgow have published a series of cases treated with the highly immune serum of patients who have recovered from the disease with encouraging results.

**MENIUS—MENIPUS**

MENIUS, of Gadara in Coele-Syria, Greek cynic and satirist, lived during the 3rd century B.C. According to Diogenes Laërtius (vi. 8) he was originally a slave, amassed a fortune as a money-lender, lost it, and committed suicide through grief. His works (written in a mixture of prose and verse) are all lost. He discussed serious subjects in a spirit of railley, and especially delighted in attacking the Epicureans and Stoics. His writings exercised considerable influence upon later literature. One of the dialogues attributed to Lucian, his avowed imitator, who frequently mentions him, is called Meniuss. But this dialogue is regarded with suspicion, and since the sub-title ("The Oracle of the Dead") resembles that of a work ascribed to Meniuss by Diogenes Laërtius, it has been suggested that it is really the work of Meniuss himself, or at any rate imitated from his Nekyia by the author, whether Lucian or another. It is well known that the Menippian satires of M. Terentius Varro, the fragments of which give an idea of this kind of composition, were called after Meniuss of Gadara (see Teufel-Schwake, *Hist. of Roman Literature*, § 165, 3).

**Bibliography.**—F. Ley, *De vita scriptoris Menippi cynici* (Cologne, 1843); R. Helm, *Lucian und Menius* (1906); C. Wachsmuth, *Sillographum graecorum rerumque Graeciae* (1858), with an account of Meniuss and similar writers. Meniuss found an imitator in later times in Justus Lipsius, author of a *Satyras menippae* (1627) in 10 books, published in 1627. The work was said to have been written by the scholar poet laureate; and in the authors of the famous *Satyras Menippeae* (1593; latest editions by C. Marcelli, Lipsia, 1882; J. Frank, Oppeln, 1884), written against the Holy League during the reign of Henr IV.

MENIUS, JUSTUS (1499–1558), Lutheran theologian, whose name is Latinized from Jost or Just (i.e. Jodocus) Menig, was born at Fulda, of poor but respectable parents, on the 13th of December 1499. Entering the University of Erfurt in 1514, he took the bachelor's degree in 1515, the master's in 1516. At this time, in association with the keen humanists Conrad Mutian, Crotus Rubeanus and Eoban Hess, he was of sceptical tendency; most of his life he spent in the university; under the teaching of Melanchthon and the preaching of Luther. After travel in Italy (1512–1513) he was appointed (1513) town's preacher at Wittenberg, but was soon transferred to the charge of Mühlberg, under Erfurt. Here he published his commentary on Acts (1524) and married. He resigned his charge (1525) and opened a school at Erfurt, but the town council insisted on his resuming his ministry, appointing him preacher in St Thomas', Erfurt. He worked in conjunction with Luther's friend, John Lange, and was opposed by the Franciscans under Conrad King. Hence he left for Gottinga (1528), resumed teaching, and enjoyed the friendship of Friedrich Myconius. Duke John of Saxony had placed him on the commission for church visitation in Thuringia, and in 1520 appointed him pastor and superintendent at Eisenach, where for eighteen years he administered church affairs with tact, and fostered the spread of education. In 1529 he brought out his *Oeconomia christiana* (a treatise in German, on the right ordering of a Christian household) with a dedication to Sibyl of Saxony and a preface by Luther. His tractate, written in concert with Myconius, controversy *Der Wiedertäler Lehrle und Geheimniss* (1530) was also prefixed by Luther. The reversion to the Roman communion of his old friend Crotus led to his mendiant, *Responsio amici* (1532, anon.) to the *Apologia* (1531) of Crotus. He took his part in the theological disputations of the time, at Marburg (1520), the Concordia at Wittenberg (1536), the Convention at Schmallkalden (1537), the discussions at Hagenau and Worms (1540). His tractate (1542) against the permission of bigamy in the case of Philip of Hesse was not allowed to be printed (the manuscript is in the Heidelberg university library). In 1542 he removed to Mühlhausen, being appointed by Duke Henry of Saxony for the ordering of the church there. On the death of Myconius (1540) he was entrusted with the oversight of Got, in addition to that of Eisenach; to Got he returned in 1547. The remainder of his life was not happy. He was against the Leipzig *Interim* (1548) with his compromise on some Catholic usages, and was involved in controversies and quarrels; with Georgius Merula, against whom he maintained the need of exorcism in
MENKEN—MENNO SIMONS

baptism; with Osian's adherents in the matter of justification; with his colleague, Nicholas von Amstorf, to whom he had resigned the Eisenach superintendency; with Flacinus Illyricus, and others. He lost favour with Duke John Frederick of Saxony, fell into bad health, was deposited (1555) from his offices, and was disappointed in his hopes of being reinstated, after the colloquy at Eisenach (1556). He died at Leipzig on the 11th of August 1558. He was twice married, and had several sons, of whom Eusebius held a chair of philosophy at Wittenberg, and married Melanchthon's grand-daughter, Anna Sabinus. Schmidt gives a full bibliography of the numerous writings of Menius, who translated several of Luther's biblical commentaries into German. His Oeconomia was reprinted in 1855.

See G. L. Schmidt, Justus Mennis, der Reformator Thüringens (1857); in Allgemeine deutsche Biographie (1888); in Kurzbiographien, in Halberstädter Realencyclopaedie (1903).

MENKEN, ADAH ISAACS (1835—1868). American actress, was born in New Orleans, the daughter of a Spanish Jew, her name being Dolores Adios Fuertes. Left in poverty at the age of thirteen, she made her first appearance as a dancer in her native city. She had a great success there and in other southern cities, including Havana, and she afterwards aspired to act in serious parts. In 1856 she married John Isaacs Menken, translated Adios to Adah, and thus took the name she thereafter bore through various matrimonial ventures. In 1864 she appeared at Astley's in London as Mazeppa, a performance of an athletic dramatic type suited to her fine physique. In England and France she became intimate with many literary men—Swinburne, Charles Reade, Dickens (to whom she dedicated in 1868 a volume of verse, Infelicia), Gautier and Dumas the elder. Paris saw her for a hundred nights in Les Pirates de la S converse, and she also played in Vienna and again in London. She died in Paris on the 10th of August 1868.

MENNONITES, a body of religious men who take their name from Menno Simons (see below), the most valued exponent of their principles. They maintain a form of Christianity which, discarding the sacerdotal idea, owns no authority outside the Bible and the enlightened conscience, limits baptism to the believer, and lays stress on those precepts which vindicate the sanctity of human life and of a man's word. The place of origin of the views afterwards called Mennonite (see Baptists) was Zürich, where in 1523 a small community left the state church and (from Jan. 18, 1525) adopted the tenet of believers' baptism. Unlike other Reformers, they denied at once the Christian character of the existing church and of the civil authority, though, in common with the first Christians, it was their duty to obey all lawful requirements of an alien power. By Protestants as much as by Catholics this position was not unnaturally regarded as subversive of the established foundations of society. Hence the bitter persecutions which, when the safety of toleration was not imagined, made martyrs of these humble folk, who simply wished to cultivate the religious life apart from the world. There was something in this ideal which answered to that medieval conception of separation from the world which had been revived middle-class society in Europe; and the revolt from Rome had prepared many minds to accept the further idea of separation from the church, for the pursuit of holiness in a society pledged to primitive discipline. Hence the new teaching and praxis spread rapidly from Switzerland to Germany, Holland and France. While the horrors of the Münster fanaticism, which culminated in 1534, made Anabaptism a byword, and increased the severity of persecution directed against all Baptists indiscriminately, the reaction against the formal errors of the Münster experiment increased also the adherents of communities which discarded the sword; thus Menno was brought into their ranks. Each community was independent, united with others only by the bond of love. There was no hierarchy (as with the Filiatists), but "elders" chosen by the members, among them the "elders" for administering baptism and the Lord's Supper; an arrangement so readily renewed that the sure way of putting down such a body was the execution of all its constituents, often by drowning, an appropriate end, according to Zwingli's quip. The remnant of the Swiss Mennonites (not tolerated till 1710) broke in 1630 into two parties, the Uplanders (or Amish, from their leader Jacob Amen) holding against the Lowlanders that excommunication of husband or wife dissolved marriage, and that razors and buttons were unlawful. In Holland the Mennonites have always been numerous. An offshoot from them at Rijnsburg in 1629, founded by the four brothers, farmers, Van der Kotte, and named Collegianten from their meetings, termed collegia (thus, as not churches, escaping the penal laws), has been compared to the Plymouth Brethren, but differed in so far as they required no conformity of religious opinion, and recognized no office of teacher. With them, as Martineau notes, Spinoza had "an intense fellow-feeling." Later, the exiled Socinians from Poland (1660) were in many cases received into membership. There had previously been oversights, more than once, for union with Mennonites on the part of Polish Socinians, who agreed with them in the rejection of oaths, the refusal to take human life, the consequent abstinence from military service and magisterial office, and in the Biblical basis of doctrine; differences of doctrinal interpretation precluded any fusion. In Holland the Mennonites were exempted from military service in 1575, from oath-taking in 1585, from public office in 1617. In Zeeland exemption from military service and oaths was granted in 1577; afterwards, as in Friesland, a heavy poll tax was the price of exemption from military service; but since 1795 they have enjoyed a legal exemption from oath-taking. In France the Mennonites of the Vosges were exempted from military service in 1793, an exemption confirmed by Napoleon, who employed them in hospital service on his campaigns. That he did not exempt the Dutch Mennonites is due to the fact that they had ceased to present a united front of resistance to military claims (Martineau); in fact they sent a large band of volunteers to Waterloo (Barclay). While in Germany the Mennonites exist in considerable numbers, more important are the German Mennonite colonies in southern Russia, brought there in 1786 by Catherine II., and freed, by the grant of complete religious liberty, from the hardships imposed by Prussian military law. These colonies have sent many emigrants to America, where their oldest community was settled (1683) at Germantown, Pennsylvania. Their settlement in Canada dates from 1786. Among the Mennonites there are three sections, and a progressive party, known as New School Mennonites.

S. Cramer gives (1903) the following statistics: in all, some 250,000 members, of whom over 80,000 are in the United States, 70,000 in Russia (apart from the White Sea), 30,000 in Holland, 20,000 in Canada, 18,000 in Germany, 15,000 in Switzerland, 800 in France, and the same number in Poland and Galicia.

MENNO SIMONS (1492—1559), religious leader, was born in 1492 at Witmarsum in Friesland. Of his parentage (apart from his patronymic) and education nothing is known. He was not a man of learning, nor had he many books; for his knowledge of early Christian writers he was partly indebted to the Chronica or compilations of Sebastian Frac. At the age of twenty-four he entered the priesthood, becoming one of two curates under the incumbent of Pingium, a village near his birthplace. He accused himself, with the other clergy, of lax and self-indulgent living. Doubts about transubstantiation made him uneasy; some of Luther's tracts fell in his way, and he was comforted by Luther's dictum that salvation does not depend on human dogmata. Hence he began to study the New Testament. The question as to the right age for baptism came up; he found this an open matter in the early church. Then they took it in March 1531, at Leeuwarden, of the tailor Sake Freeks, who had been rebaptized in the previous December at Emden, introduced further questions. Menno was not satisfied with the inconsistent answers which he got from Luther, Bucer and Bullinger; he resolved to rely on Scripture alone, and from this time describes his preaching as evangelical, not sacramental. In 1532 he exchanged his curacy for a living at Witmarsum, in response to a popular call. Anabaptism of the Münster type
repelled him. His first tractate (1535, first printed 1627) is directed against the "horrible and gross blasphemy of John of Leiden"—though the genuineness of this tract has been doubted. A brother of Menno joined the insurgent followers of John Matthyszoon, and was killed at Holsten (A.D. 1535). Among the leaders by whom these poor people had been betrayed, Menno blamed himself for not having shown them a straight course. Accordingly on the 15th of January 1536 he left the Roman communion. There were now among the so-called Anabaptists four parties, the favourers of the Münster faction, the Batenburgers, extremists, the Melchiorites and the Obbenites. For a time Menno remained aloof from both Melchior Hofman and Obbe Philipsz. Before the year was out, yielding to the prayer of six or eight persons who had freed themselves from the Münster spell, he agreed to become their minister, and was set apart (January 1537) to the eldership at Groningen, with imposition of hands by Obbe Philipsz, who is regarded as the actual founder of the Mennonite body. In fact, Obbe left the body and is stigmatized as its Demas. Menno repudiated the formation of a sect; those who had experienced the "new birth" were to him the true Christian church, which was limited by no decree of reparation. His Christology was in the main orthodox, though he rejected terms (such as Trinity) which he could not find in Scripture, and held a Valentinian doctrine of the celestial origin of the flesh of Christ. His church discipline was drawn from the Swiss Baptists. Silent prayer was a feature of the worship; sermons were without texts. Neither baptism (by immersion) nor the Lord’s Supper (with the accompaniment of feet-washing) were considered divine ordinances which reflected the believer’s inward state. Marriage with outsiders was prohibited; women had no part in church government. Oaths and the taking of life were absolutely forbidden; hence the magistracy and the army were for the Mennonite unlawful callings; but magistrates were to be obeyed in all things not prohibited by Scripture. The subsequent career of Menno was that of an active missionary, his changes of place, often compulsory, are difficult to trace. He was apparently much in East Friesland till 1541; in North Holland, with Amsterdam as centre, from 1541 to 1543; again till 1545 in East Friesland (where he held a disputation at Emden with John à Lasco in January 1544); till 1547 in South Holland; next, about Lübeck; at Wismar in 1553–1554 (he held two disputations with Martin Micronius at Norden in February 1554); lastly at Wustenfelde, a village near Oldeslo, between Hamburg and Lübeck, where he died on the 13th of January 1559. He had married one Gertrude at Groningen, and left a daughter, by whom the dates of his birth and death were communicated to F. J. Twisch, for his Chronyk (1619).

Menno’s writings in Plattdeutsch, printed at various places, are numerous, with much sameness, and what an untrained mind would call wool-gathering; through them shines a character attractive by the sincerity of its simple and warm spirituality, the secret of Menno’s influence. The collection of his Opera Omnia Theologica (Amsterdam, 1681), also in a Dutch version, comprises twenty-three tractates, with reference to nine unprinted. His main principles will be found in his Dat Fundament des Christenlyken Leers (1593, 1600). A selection (Gedenkblätter) from his writings, in a German version, in honor of the supposed tercentennial of his death was edited by F. J. Twisch (1619), and in 1681 by the fourth dioecesan synod of Dirk Philipsz (1504–1570), brother of Obbe, and Menno’s herman. His writings are published in English at Elkhart, Indiana.

Since the publication of the Leren (1857) by A. M. Kramer, light has been thrown on Menno’s life and writings by the research of Dr. Hendrik Schipper (Hist. of Conferences and Conferences of Dirk Philipsz, 1504–1570), brother of Obbe, and Menno’s herman. His writings are published in English at Elkhart, Indiana.

See Van der Aa, Biographisch woordenboek der Nederlanden (1866); R. Barclay, Inner Life of Religious Societies of the Commonwealth (1876) for a good account of Mennonite anticipations of Quaker views and the influence of John Foxe and Lewis (1524–1603), and of J. J. Schmoller (1892); V. M. Reimann, Mennonitische Simonsis quaesiturit (1884); S. Kramer, in Hauck’s Realencyklopadie (1903); a separate article in the English, Mennonit, by S. Kramer, gives a survey of the origin and ramifications of the movement in Europe and America. (A. G. O.)

MENOMINEE, a city and the county-seat of Menominee county, Michigan, U.S.A., on Green Bay, at the mouth of the Menominee river, opposite Marinette, Wisconsin, at the southern extremity of the upper peninsula. Pop. (1890), 10,680; (1900), 12,818, of whom 4186 were foreign-born; (1910 census), 10,507. It is served by the Chicago & North-Western, the Chicago, Milwaukee & St Paul, the Wisconsin & Michigan, and the Ann Arbor railways, and is connected by five bridges with Marinette, Wisconsin. Menominee has several parks, and harbour and dock facilities for lake vessels. It is one of the largest lumber centres in the United States; it has excellent water power, and there are manufactures of wire, steel, electrical appliances, mill and mining machinery, shoes, beet sugar and paper. The use of beet-pulp instead of Indian corn ensilage for dairy cows has promoted the dairying industry in the city.

A trading post was established here in 1790, but settlement was not begun until 1833. Menominee became the county-seat in 1874, was chartered as a city in 1883, and in 1891 and in 1901 it was re-chartered; in 1903 an amendment to the charter created a municipal court. The city is named after the Menominee Indians, an Algonquian tribe formerly ranging over a considerable territory in Wisconsin and Michigan, who seem to have been first visited by whites in 1634, when Nicolet found them at the mouth of the Menominee river, and now number about 1600, most of them being under the Green Bay school superintendency, Wisconsin. The name is the Chippewa word for wild rice, which formed part of the food of the tribe.

MENOMONIE, a city and the county-seat of Dunn county, Wisconsin, U.S.A., about 56 m. E. of St Paul, Minnesota, on the Red Cedar river. Pop. (1890), 5491; (1900), 5655, of whom 1772 were foreign-born; (1900), 5479; (1910), 5086. It is served by the Chicago, Milwaukee & St Paul, and the Chicago, St Paul, Minneapolis & Omaha railways. The city is widely known for its institutions, for the most part founded or supported by James Huff Stout (1848–1910), a prominent local lumberman. Among them are the Mabel Tainter Memorial Library, the Dunn County School of Agriculture, the Dunn County Normal Training School, the Stout Institute for the training of teachers of domestic science &c., institutions in which public school children receive physical training. The city has grain elevators, and manufactures of bricks and tiles, foundry and machine shop products, carriages and wagons and flour. Menomonee is an important market for dairy products and livestock. Menomonee was settled about 1846 and was chartered as a city in 1882. The first free travelling library in the state was established here in 1856 by James Huff Stout.

MENS, and MAREA, semi-nomad pastoral tribes of Africans occupying part of the Abyssinian highlands included in the Italian colony of Eritrea, and the adjacent coast plains of the Red Sea. They have for neighbours the Habab and Beni-Amr tribes, as well as Abyssinians. The Marea are found chiefly in the valley of the Khor Asseba, the Mensa dwelling farther north. These tribes claim Arab origin, tracing their descent from an uncle of the Prophet. Under Abyssinian rule they were Christians, but became Mahommedans in the 19th century. They speak a dialect of Tigrin (Abyssinian). On the death of a Marea the head of every dependent tigré or slave family must give his heirs a cow. The tribes avenge an illegitimate birth by putting parents and child to death.

MENSHIKOV, ALEXANDER DANILOVICH, Prince (1663–1729), Russian statesman, was born not earlier than 1660 nor later than 1663. It is disputed whether his father was an ostler or a bargee. At the age of twenty he was gaining his livelihood in the streets of Moscow as a vendor of meat-pies. His handsome and smart tall statured the attention of François Lefort, Peter’s first favourite, who took him into his service and finally transferred him to the tsar. On the death of Lefort in 1699, Menshikov succeeded him as prime favourite. Ignorant, brutal, grasping and corrupt as he was, he deserved the confidence of his master. He could drill a regiment, build a frigate, administer a province, and decapitate a rebel with equal facility. During the tsar’s first foreign tour, Menshikov worked by his side in the dockyards of Amsterdam, and acquired a thorough knowledge of colloquial Dutch and German. He took an active

part in the Azov campaigns (1693–96), and superseded Ogilvie as commander-in-chief during the retreat before Charles XII. in 1708. He was frequently participating in the battle of Holowczyn, the reduction of Mazepe, and the crowning victory of Poltava (June 26, 1709), where he won his marshal’s baton. From 1709 to 1714 he served during the Courland, Holstein and Pomeranian campaigns, but then, as governor-general of Ingria, with almost unlimited powers, was entrusted with a leading part in the civil administration. Menshikov understood perfectly the principles on which Peter’s reforms were conducted, and was the very hand of the tsar in all his gigantic undertakings. But he abused his omnipotent position, and his depredations frequently brought him to the verge of ruin. Every time the tsar returned to Russia he received fresh accusations of peculation against “his Serene Highness.” Peter’s first serious outburst of indignation (March 1711) was due to the prince’s looting in Poland. On his return to Russia in 1712, Peter discovered that Menshikov had winked at wholesale corruptions in his own governor-generalship. Peter warned him “for the last time” to change his ways. Yet, in 1713, he was implicated in the famous Solov’ev process, in the course of which it was demonstrated that Menshikov had embezzled the contents of a box containing state documents. He only owed his life on this occasion to a sudden illness. On his recovery Peter’s fondness for his friend overcame his sense of justice. In the last year of Peter’s reign fresh frauds and defalcations of Menshikov came to light, and he was obliged to appeal for protection to the empress Catherine. It was chiefly through the efforts of Menshikov and his colleague Tolstoi that, on the death of Peter, in 1725, Catherine was raised to the throne. Menshikov was committed to the Petrine system, and he recognized that, if that system were to continue, Catherine was, at that particular time, the only possible candidate. Her name was a watchword for the progressive faction. The placing of her on the throne meant a final victory over ancient prejudices, a vindication of the new ideas of progress. During her short reign (February 1725–May 1727), Menshikov was practically absolute. On the whole he ruled well, his difficult position serving as some restraint upon his natural inclinations. He contrived to prolong his power after Catherine’s death by means of a forged will and a coup d’état. While his colleague Tolstoi would have raised Elizabeth Petrovna to the throne, Menshikov set up the youthful Peter II., son of the tsarevich Alexius, with himself as dictator during the prince’s minority. He now aimed at establishing himself definitely by marrying his daughter Mary to Peter II. But the old nobility, represented by the Dolgorukis and the Golitsins, united to overthrow him, and he was deprived of all his dignities and offices and expelled from the capital (Sept. 9, 1727). Subsequently he was deprived of his enormous wealth, and he and his whole family were banished to Berezov in Siberia, where he died on the 12th of November 1729.

Poel, R. Nisbet Bain, The First Romanovs (London, 1905); ibid, The Turks of Peter the Great, ch. 2–4 (Westminster, 1897). (R. N. B.)

MENSHEKOV, ALEXANDER SERGEIEVICH, PRINCE (1787–1869), great-grandson of the preceding, was born on the 11th of September 1787, and entered the Russian service as attaché to the embassy at Vienna. He accompanied the emperor Alexander throughout his campaigns against Napoleon, and retired from army service in 1823. He then devoted himself to naval matters, became an admiral in 1834, and put the Russian navy, which had fallen into decay during the reign of Alexander, on an efficient footing. At the time of the dispute as to the Holy Places he was sent on a special mission to Constantinople, and when the Crimean war broke out he was appointed commander-in-chief by land and sea. He commanded the Russian army at the Alma and in the field operations round Sevastopol. In March 1855 he was recalled, ostensibly and perhaps really, on account of failing health. He died on the 2nd of May 1860 at St Petersburg.

MENSURATION (Lat. mensura, a measure), the science of measurement; or, in a more limited sense, the science of numerical representation of geometrical magnitudes.

1. Scope of the Subject.—Even in the second sense, the term is a very wide one, since it comprises the measurement of angles (plane and solid), lengths, areas and volumes. The measurement of angles belongs to trigonometry, and it is convenient to regard the measurement of the lengths of straight lines (i.e. of distances between points) as belonging to geometry or trigonometry; while the measurement of curved lengths, except in certain special cases, involves the use of the integral calculus. The term “mensuration” is therefore restricted to the measurement of areas and volumes, and of certain simple curved lengths, such as the circumference of a circle.

2. This restriction is to a certain extent arbitrary. The statement that, if the adjacent sides of a rectangle are represented numerically by 3 and 4, the diagonal is represented by 5, is as much a matter of mensuration as the statement that the area is represented by 12. The restriction is really determined by a difference in the methods of measurement. The distance between two points can, at any rate in theory, be measured directly, by successive applications of the unit of measurement. But an area or a volume cannot generally be measured by successive applications of the unit of area or volume; intermediate processes are necessary the result of which is expressed by a formula. The chief exception is in the use of liquid measure; this is of importance from the educational point of view (§ 12).

3. The measurement is numerical, i.e. it is representation in terms of a unit. The process of determining the area or volume of a given figure therefore involves two separate processes; viz. the direct measurement of certain magnitudes (usually lengths) in terms of a unit, and the application of a formula for determining the area or volume from these data. Mensuration is not concerned with the first of these two processes, which forms part of the art of measurement, but only with the second. It might, therefore, be described as that branch of mathematics which deals with formulae for calculating the numerical measurements of curved lengths, areas and volumes, in terms of numerical data which determine these measurements.

4. It is also convenient to regard as coming under mensuration the consideration of certain derived magnitudes, such as the moment of a plane figure with regard to a straight line in its plane, the calculation of which involves formulae which are closely related to formulae for determining areas and volumes.

5. On the other hand, the scope of the subject, as described in § 3, is limited by the nature of the methods employed to obtain the results which can be applied to actual cases. Up to a certain point, formulae of mensuration may be obtained by the use of elementary arithmetical or geometrical methods. Beyond this point, analytical methods must be adopted, and the student passes to trigonometry and the infinitesimal calculus. These investigations lead, in turn, to further formulae, which, though not obtainable by elementary methods, are nevertheless simple in themselves and of practical utility. If these are included in the description “mensuration,” the subject thus consists of two heterogeneous portions—elementary mensuration, comprising methods and results, and advanced mensuration, comprising certain results intended for practical application.

6. Mensuration, then, is mainly concerned with quadrature-formulae and cubature-formulae, and, to a not very clearly defined extent, with the methods of obtaining such formulae; a quadrature-formula being a formula for calculating the numerical
representation of an area, and a cubature-formula being a formula for calculating the numerical representation of a volume, in terms, in each case, of the numerical representations of particular data which determine the area or the volume.

7. This use of formulae for dealing with numbers, which express magnitudes in terms of units, constitutes the broad difference between mensuration and ordinary geometry, which knows nothing of units. Mensuration involves the use of geometrical theorems, but it is not concerned with problems of geometrical construction. The area of a rectangle, for instance, is found by calculation from the lengths of the sides, not by construction of a square of equal area. On the other hand, it is worth noticing that the words "quadrature" and "cubature" are originally due to geometrical rather than numerical considerations; the former implying the construction of a square whose area shall be equal to that of a given surface, and the latter the construction of a cube whose volume shall be equal to that of a given solid.

8. There are two main groups of subjects in which practical needs have tended to develop a separate science of mensuration. The first group comprises such subjects as land-surveying; here the measurements in the elementary stages take place in a plane, and the consideration of volumes necessarily constitutes a later stage; and the figures to be measured are mostly not movable, so that triangulation plays an important part. The second group comprises the mechanic arts, in which the bodies to be measured are solid bodies which can be handled; in these cases plane figures appear mainly as sections of a solid. In developing a system of mensuration-formulae the importance of this latter group of cases must not be overlooked.

A third group, of increasing importance, comprises cases in which curves or surfaces arise out of the application of graphic methods in engineering, physics and statistics. The general formulae applicable to these cases are largely approximative.

9. Relation to Other Subjects.—As a result of the importance both of the formulae obtained by elementary methods and of those which have involved the previous use of analysis, there is a tendency to dissociate the former, like the latter, from the methods by which they have been obtained, and to regard mensuration as consisting of those mathematical formulae which are concerned with the measurement of geometrical magnitudes (including lengths), or, in a slightly wider sense, as being the art of applying these formulae to specific cases. Such a body of formulae cannot, of course, be regarded as constituting a science; it has no power of development from within, and can only grow by accretion. It may be of extreme importance for practical purposes; but its educational value, if it is studied apart from the methods by which the formulae are obtained, is slight. Vitality can only be retained by close association with more abstract branches of mathematics.

10. On the other hand, mensuration, in its practical aspect, is of importance for giving reality to the formulae themselves and to the principles on which they are based. This applies not only to the geometrical principles but also to the arithmetical principle—viz., the importance in the earlier stages, to keep geometry, menuration and arithmetic in close association with one another; menuration forming, in fact, the link between arithmetic and geometry.

11. It is in reference to the measurement of areas and volumes that it is of special importance to illustrate geometrical truths by means of concrete cases. That the area of a parallelogram is equal to the area of a rectangle on the same base and between the same parallels, or that the volume of a cone is one-third that of a cylinder on the same base and of the same height, may be established by a proof which is admitted to be rigorous, or be accepted in good faith without proof, and yet fail to be a matter of conviction, even though there may be a clear conception of the relative lengths of the diagonal and the side of a square or of the relative contents of two vessels of different shapes. The failure seems (§ 2) to be due to difficulty in realizing the numerical expression of an area or a solid in terms of a specified unit, while the same difficulty does not arise in the case of linear measure or liquid measure, where the number of units can be ascertained by direct geometrical figures. The difficulty is perhaps less for volumes than for areas, on account of the close relationship between solid and fluid measure.

12. The main object to be aimed at, therefore, in the study of elementary mensuration, is that the student should realize the possibility of the numerical expression of areas and volumes. The following are some important points.

(i) The double aspect of an area should be borne in mind; i.e. area should be treated not only as length multiplied by length, but also as volume divided by thickness. There are, indeed, certain advantages in preferring the latter to the former, and in proceeding from volumes in areas rather than from areas to volumes. While, for instance, it may be difficult to realize the equality of area of two plots of ground of different shapes, it may be easy to realize the equality of the amounts of a given material that would be required to cover them to a particular depth. This method is unconsciously adopted by the teacher who illustrates the equality of area of two geometrical figures by cutting them out of cardboard of uniform thickness and weighing them.

(ii) The very earliest stages of mensuration should be directly associated with simple arithmetical processes.

(iii) Association of solid measure with liquid measure, presenting numerical measurement in a different aspect, should be retained in the earlier stages, when the volumes of the same bodies are being measured, of the same bodies as found by the use of measures of capacity. Here, as usual, the British systems of measures produce a difficulty which would not arise under the metric system.

(iv) Solids of the same substance should be compared by measuring the weights, also by weighing, the comparison being then extended to areas of uniform thickness (see (i) above).

(v) The idea of an average may be introduced at an early stage, methods of calculating an average being left to a later stage.

13. Classification.—The methods of mensuration fall for the most part under one or other of three main heads, viz. arithmetical mensuration, geometrical mensuration, and analytical mensuration.

14. The most elementary stage is arithmetical mensuration, which comprises the measurement of the areas of rectangles and parallelepipeds. This may be introduced very early; square blocks being used for the mensuration of areas, and cubical blocks for the mensuration of volumes. The measure of the area of a rectangle is thus presented as the product of the sides, and arithmetical mensuration and arithmetical measurement are developed concurrently. The commutative law for multiplication is directly illustrated; and subdivisions or groupings of the units lead to such formulae as \(a + a\) \((b + b) = ab + ab\). Association with other branches of science is maintained by such methods as those mentioned in § 12.

The use of the square bricks familiarizes the scholar with the ideas of parallel lines, of equality of lengths, and of right angles. The conception of the right angle is strengthened, by contrast, by the use of bricks in the form of a rhombus.

15. The next stage is geometrical mensuration, where geometrical methods are applied to determine the areas of plane rectilinear figures and the volumes of solids with plane faces. The ordinary process involves three separate steps. The first step is the establishment of the exact equality of congruence of geometrical figures, in the case of plane figures, the congruence is tested by an imaginary superposition of one figure on the other; but this may more simply be regarded as the superposition, on either figure, of the image of the other figure on a contiguous plane. In the case of solid figures a more difficult geometrical abstraction is involved. The second step is the conversion of one figure into another by a process of dissection, followed by rearrangement of parts; the figure as rearranged being one whose area or volume can be calculated by methods already established. This is the process adopted, for instance, for comparison of the area of a parallelogram with that of a rectangle on the same base and of the same height. The third step is the arithmetical calculation of the area or volume of the rearranged figure. These last two steps may introduce magnitudes which have to be subtracted, and which therefore have to be treated as negative quantities in the arithmetical calculation.
MENSURATION

The difficulties to which reference has been made in § 11 are largely due to the abstract nature of the process involved in the second of the above steps. The difficulty should, wherever possible, be removed by making the process of dissection and rearrangement complete. This is not always done. To say, for instance, that the area of a right-angled triangle is half the area of the rectangle contained by the two sides, is not to say what the area is, but what it is the half of. The proper statement is that, if \( a \) and \( b \) are the sides, the area is equal to the area of a rectangle whose sides are \( a \) and \( \frac{1}{2}b \); this being, in fact, a particular case of the proposition that the area of a trapezium is equal to the area of a rectangle whose sides are its breadth and the arithmetic mean of the lengths of the two parallel sides. This mode of statement helps to establish the idea of an average. The deduction of the formula \( \frac{1}{2}ab \), where \( a \) and \( b \) are numbers, should be regarded as a later step.

Elementary trigonometrical formulae, not involving the computation of an angle as generated by rotation, belong to this stage; the additional geometrical idea involved being that of the proportionality of the sides of similar triangles.

16. The third stage is analytical mensuration, the essential feature of which is that account is taken of the manner in which a figure is generated. To prevent discontinuity of results at this stage, recapitulation from an analytical point of view is desirable. The rectangle, for instance, has so far been regarded as a plane figure bounded by one pair of parallel straight lines and another pair at right angles to them, so that the concept of "rectangularity" has had reference to boundary rather than to content; analytically, the rectangle must be regarded as the figure generated by an ordinate of constant length moving parallel to itself with one extremity on a straight line perpendicular to it. This is the simplest case of generation of a plane figure by a moving ordinate; the corresponding figure for generation by rotation of a radius vector is a circle.

To regard a figure as being generated in a particular way is essentially the same as to regard it as being made up of a number of successive elements, so that the analytical treatment involves the ideas and the methods of the infinitesimal calculus. It is not, however, necessary that the notation of the calculus should be employed throughout.

A plane figure bounded by a continuous curve, or a solid figure bounded by a continuous surface, may generally be most conveniently regarded as generated by a straight line, or a plane area, moving in a fixed direction at right angles to itself, and changing as it moves. This involves the use of Cartesian co-ordinates, and leads to important general formulae, such as Simpson's formula. The treatment of such an angle as generated by rotation, involves the investigation of the relations between trigonometrical ratios and circular measure, the application of interpolation to trigonometrical tables, and the general use of graphical methods to represent continuous variation, all imply an analytical outlook, and must therefore be deferred to this stage.

17. There are certain special cases where the treatment is really analytical, but where, on account of the simplicity or importance of the figures involved, the analysis does not take a prominent part.

(i) The circle, and the solid figures allied to it, are of special importance. A circular disc is defined as the figure generated by the rotation of a radius of constant length in a plane, and is thus essentially analytical. The ideas of the centre and of the constancy of the radius do not, however, enter into the elementary conception of the circle as a round figure. This elementary conception is of the figure as already existing, rather than of its method of description; the test of circularity being the possibility of rotation within a surrounding figure, and the figure bounded by the step being the circularity of the central section, as roughly tested (where the sphere is small) by visual perception, i.e., in effect, by the circularity of the cross-section of a circumscribing cylinder; and the ideas of the centre and of non-central sections follow later.

It seems to follow that the consideration of the area of a circle should precede the consideration of its perimeter, and that the consideration of the volume of a sphere should precede the consideration of its surface-area. The proof that the area of a circle is proportional to the square of its diameter would therefore precede the proof that the perimeter is proportional to the diameter; the former is easier than the latter because the length of a curved line as the limit of the sum of a number of straight lengths presents special difficulties. The ratio \( \pi \) would thus first appear as the ratio of the average breadth of a circle to the greatest length, practical experience being generally the inverse of the circumference as to the diameter being a secondary one. This order follows, in fact, the historical order of development of the subject.

(ii) Developable surfaces, such as the cylinder and the cone, form a special class, so far as the calculation of their area is concerned. The process of unrolling is analytical, but the unrolled area can be measured by methods not applicable to other surfaces.

(iii) Solids of revolution also form a special class, which can be conveniently treated by the two theorems of Pappus (§ 33).

18. The above classification relates to methods. The classification of results, i.e., of formulae, will depend on the purpose for which the collection of formulae is required, and may involve the grouping of results obtained by very different methods. A collection of formulae relating to the circle, for instance, would comprise not only geometrical and trigonometrical formulae, but also approximate formulae, such as Huygen's rule (§ 91), which are the result of advanced analysis.

The present article is not intended to give either a complete collection of results, or a complete collection of formulae, and therefore such only of the ordinary formulae are given which are required for illustrating certain general principles. For fuller discussion reference should be made to GEOMETRY and TRIGONOMETRY, as well as to the articles dealing with particular figures, such as TRIANGLE, CIRCLE, &c.

19. The most important formulae are those which correspond to the use of rectangular Cartesian co-ordinates. This implies the treatment of a plane or solid figure as being wholly comprised between two parallel lines or planes, regarded by convention as being vertical; the figure being generated by an ordinate or section moving at right angles to itself through a distance which is called the breadth of the figure. The length or area obtained by dividing the area or the volume of the figure by its breadth is the mean ordinate (mean height) or mean section (mean sectional area) of the figure.

Quadrature-formulae or cubature-formulae may sometimes be conveniently replaced by formulae giving the mean ordinate or mean section. In the early stages it is best to use both methods, so as to develop the idea of an average (§ 12). In the present article the formulae for area or volume will be used throughout.

20. Approximation.—The numerical result obtained by applying a formula to particular data will generally not be exact. There are two kinds of causes producing want of exactness.

(i) The formula itself may not be numerically exact. This may happen in either of two ways.

(a) The formula may involve numbers or ratios which cannot be expressed exactly in the ordinary notation. This is the case, for instance, with formulae which involve \( \pi \) or trigonometrical ratios. This inexactness may, however, be ignored, since the numbers or ratios can generally be obtained to a greater degree of accuracy than the other numbers involved in the calculation (see (ii) (b) below).

(b) The formula may only be approximate. The length of the arc of a circle, for instance, is known if the length of the chord and its distance from the middle point of the arc are known; but it may be more convenient in such a case to use a formula such as Huygen's rule than to obtain a more accurate result by means of trigonometrical tables.

(ii) The data may be such that an exact result is impossible.

(a) The nature of the bounding curve or surface may not be exactly known, so that certain assumptions have to be made, a plane or a figure being bounded by the step being the circularity of the central section, as roughly tested (where the sphere is small) by visual perception, i.e., in effect, by the circularity of the cross-section of a circumscribing cylinder; and the ideas of the centre and of non-central sections follow later.

The application of Simpson's rule, for instance, to a plane figure implies certain assumptions as to the nature of the bounding curve. Such a formula is approximate, in that it is known that the result obtained is only an approximately correct one; it differs from an approximative formula of the kind mentioned in (i) (b) above, in that it is adopted of necessity, not by choice.

(b) It must, however, be remembered that in all practical applications of formulae the data have first to be ascertained by direct or indirect measurement; and this measurement involves a certain margin of error.
The two sources of error mentioned under (a) and (b) above are closely related. Suppose, for instance, that we require the area of a circular grass-plot of measured diameter. As a matter of fact, no grass-plot is truly circular; and it might be found that if the break-up, formulae which will only give approximate results are usually classed together as rules, whether the inaccuracy lies (as in the case of Huygen's rule) in the formula itself, or (as in the case of Simpson's rule) in its application to the data.

21. It is necessary, in applying formulae to specific cases, not only, on the one hand, to remember that the measurements are only approximately, but also, on the other hand, to give to any ratio such as $\pi$ a value which is at least more accurate than the measurements. Suppose, for instance, that in the example given in § 20 the diameter as measured is 15 ft. 3 in. If we take $\pi \approx 3.14$, and find the area to be 26288-865 sq. in. = 182 sq. ft. 80-865 sq. in., we make two separate mistakes. The main mistake is in giving the result as true to a small fraction of a square inch; but, if this degree of accuracy had been possible, it would have been wrong to give $\pi$ a value which is in error by more than 1 in 2000.

Calculating inches and feet are sometimes performed by means of duodecimal arithmetic; i.e., in effect, the tables of square measure and of cubic measure are multiplied by the insertion of intermediate units. For square measures—

12 square inches = 1 superficial prime,
12 superficial primes = 1 square foot;
while for cubic measure—

12 cubic inches = 1 solid second,
12 solid seconds = 1 solid prime,
12 solid primes = 1 cubic foot.

When an area has been calculated in terms of square feet, primes and square inches, the primes and square inches have to be reduced to square inches; and similarly with the calculation of volumes. The three cases in the calculation of volumes are: (i) a rectangle, (ii) a square, and (iii) a cube. The formulae for these cases are:

\[ \text{Area} = \text{length} \times \text{breadth} \]
\[ \text{Volume} = \text{length} \times \text{breadth} \times \text{height} \]

For the case of the trapezium, it is important to note that the area of a trapezium is equal to the area of the piece GEHF of the original trapezium. The right trapezium so constructed may be called the equivalent right trapezium. In the case of a parallelogram, if the right trapezium is a rectangle; in the case of a triangle, it is a right-angled triangle.

24. If we take a series of right trapezium, such that one side (§ 23) is equal to one side of the second, the other side of the second is equal to one side of the third, and so on, and place them with their bases in a straight line and their equal sides adjoining each other, we get a figure such as Fig. 2, which has two parallel sides $MA$ and $SF$, a base MS at right angles to these, and the remainder of its boundary from $A$ to $F$ rectilinear, no part of the figure being outside the space between $MA$ (produced) and $SF$ (produced). A figure of this kind will be called a trapezoid.

If from the other angular points $B$, $C$, $D$, $E$, perpendiculars $BN$, $CP$, $DQ$, $Ft$, the base $MS$ (fig. 3), the areas $M$, $N$, $P$, $Q$, $R$ of the triangle by $A$, $B$, $C$, $D$, $E$ may be obtained, the ordinates of the points $A$, $B$, $C$, $D$, $E$ from the figure, and the product $MN$, $NP$, $PQ$, $QR$, of the base are the projections of the sides $AB$, $BC$, $CD$, $DE$, $EF$ on the base.

Another special case is that in which the distances $MN$, $NP$, $PQ$, $QR$ are all equal. If this distance is $b$, then the area of the trapezium is $\frac{1}{2}(MN+NP+PQ+QR+QF)$. The lines $MA$, $NB$, $PC$, $DQ$, are called the ordinates of the points $A$, $B$, $C$, $D$, $E$.

25. To find the area of any rectilinear figure, various methods are available.

(i) The figure may be divided into triangles. The quadrilateral, for instance, consists of two triangles, and its area is the product of the length of one of its sides and the sum of the two other sides. Thus, each vertex of the figure is divided by radii drawn from its centre.

(ii) Suppose that two angular points, $A$, and $E$, are joined (fig. 3) so as to form a diagonal $AE$, and that the whole of the figure lies between lines through $A$ and $E$ at right angles to $AE$. Then the figure is (usually) the sum of the triangles on base $AE$, and its area can be calculated as in § 24. If $BN$, $CP$, $DQ$, $Ft$, $..$. $FS$, $GT$ are the perpendiculars from the vertices $B$, $C$, $D$, $E$, $F$, $G$ to $AE$, the ordinates $NB$, $PC$, $..$. are called the offsets from the diagonal to the angular points.

The area of the polygon in Fig. 3 is given by the expression

\[ \frac{1}{2}(AP \times NB+NC \times PC+PE \times QD \times ET \times SF \times SA) \]

It should be noticed (a) that $AP$, $NB$, $NC$, $PC$, $PE$, $QD$, $ET$, $SF$, $SA$, $TG$ are areas that are not included in the expression, and (b) that in § 23, if $AN$ and $NB$ are regarded as positive, then $SF$, $TG$, $ET$ and $SA$ are negative, but the products $ET \times SF$ and $SA \times TG$ are positive.

Negative products will arise if in moving from $A$ to $E$ along the perimeter of either side of the projection of the moving point does not always move in the direction of $AE$.

(iii) Take any straight line intersecting or not intersecting the figure, and draw perpendiculars $AA'$, $BB'$, $CC'$, $DD'$, $EE'$, $FF'$, $GG'$ to this line. Then, with perpendiculars distances $a \times AA'$, $b \times BB'$, $c \times CC'$, $d \times DD'$, $e \times EE'$, $f \times FF'$, $g \times GG'$.

(iv) The figure may be replaced by an equivalent trapezoid, on the evidence explained in § 23. Take any base $XXX$, and draw lines at right angles to this base through all the angular points of the figure.
MENSURATION

Let the lines through B, C, D and F (fig. 4) cut the boundary of the figure again in B', C', D' and F', and meet the base X'X in K, L, M, N and P; the points A and E being at the extremities of the figure, and the lines through them meeting the base in a and e. Then, if we take ordinates Kk, Ll, Mm, Nn, Pp, equal to B'B, GG, CC, DD, FF, the figure abgdfe will be the equivalent trapezoid, and any ordinate Oo, taken from the top of this trapezoid will be equal to the portion of this ordinate (produced) which falls within the original figure.

26. Volumes of Solids with Plane Faces.—The following are expressions for the volumes of some solid figures.

(i) Cube: side a. Volume = a³.

(ii) Rectangular parallelepiped: sides a, b, c. Volume = abc.

(iii) Right prism. Volume = length of edge X area of end.

(iv) Oblique prism. Volume = height X area of end = length of edge X area of cross-section; the "height" being the perpendicular distance between the two ends.

The parallelepiped is a particular case.

(v) Pyramid with rectilinear base. Volume = height X 1/3 area of base.

The tetrahedron is a particular case.

(vi) Wedge: parallel edges a, b, c; area of cross-section S. Volume = (a+b+c)S.

This formula holds for the general case in which the base is a trapezium; the wedge being thus formed by cutting a triangular prism by any two planes.

(vii) Frustum of pyramid with rectilinear base: height h; areas of ends (i.e. base and top) A and B. Volume = k. (A+√AB+B). 27. The figures considered in § 26 are particular cases of the prismoid (or prismatoid), which may be defined as a solid figure with two parallel plane rectilinear ends, each of the other (i.e. the lateral) faces being a triangle with an angular point in one end of the figure and an opposite side bounding face in the other. Two opposite bounding faces in the same plane may together make a trapezium. More briefly, the figure may be defined as a polyhedron with two parallel faces containing all the vertices.

If A and S are the ends of a prismoid, A and B their areas, h the perpendicular distance between them, and C the area of a section by a plane parallel to R and S and midway between them, the volume of the prismoid is

\[ \frac{4}{3}bh(a+4c+B). \]

This is known as the prismoidal formula.

The formula is a deduction from a general formula, considered later (§ 58), and may be verified in various ways. The most instructive is to subtract (by addition or subtraction) of simpler figures, which are particular cases of it.

(i) Let R and S be two opposite edges of a tetrahedron. The tetrahedron may be regarded as the difference of a wedge with parallel ends, one of the edges being R, and a pyramid whose base is a parallelogram, one side of the parallelogram being S (see fig. 9, § 58). Hence, by (i) and (ii), the formula holds for this figure.

(ii) For the prismoid in general let ABCD . . . be one end, and abcd . . . the other. Take any point P in the latter, and form triangles by joining P to each of the sides AB, BC, . . . ab, bc, . . . of the ends, and also to each of the faces built up (by addition or subtraction) of simpler figures, which are particular cases of it.

The expression is divided into a pyramid with vertex P and base ABCD . . ., and a series of tetrahedra, such as PABe or PAab. By (i) and (iii), the formula holds for each of these figures; and therefore it holds for the prismoid as a whole.

Another method of verifying the formula is to take a point Q in the mid-section, and form triangles by joining Q to each of the sides AB, BC, . . . ab, bc, . . . of the ends, and also to each of the faces built up (by addition or subtraction) of simpler figures, which are particular cases of it.

The expression is divided into a pyramid with vertex Q and base ABCD . . ., and a series of tetrahedra having Q as one vertex.

28. The Circle and Allied Figures.

The mensuration of the circle is founded on the property that the areas of different circles are proportional to the squares on their diameters.

Denoting the constant ratio by \(\sqrt{\pi}\), the area of a circle is \(a^2\), where \(a\) is the radius, and \(\pi\) is therefore \(\pi \times 1\). The length of arcs subtended by them at the centre, we get the idea of circular measure.

Let O be the common centre of two circles, of radii \(a\) and \(b\), and let radii enclosing an angle \(\theta\) (circular measure) cut their circumferences in A, B and C, D respectively (fig. 5). Then the area of ABDC is

\[ \frac{\theta}{360} \times \pi(a^2 + b^2 + 2ab\cos \theta). \]

If we bisect AB and CD in P and Q respectively, and describe the circle (circumcircle) of a circle with the figure for the common arc is

\[ \frac{\theta}{360} \times \pi(b-a)^2. \]

Hence area ABDC = AB X arc PQ.

The figure ABDC is a sector of an annulus, which is the portion of a circle left after cutting out a concentric circle.

If we consider a circle as the limit of a polygon, it follows that the formulae (iii) and (v) of § 26 hold for a right circular cylinder and a right circular cone; i.e.

volume of right circular cylinder = length X area of base;

volume of right circular cone = height X 1/3 area of base.

These formulae also hold for any right cylinder and any cone.

30. The curved surfaces of the cylinder and of the cone are developable surfaces; i.e. they can be unrolled on a plane. The curved surface of any right cylinder (whether circular or not) becomes a rectangle, and therefore its area = length X perimeter of base. The curved surface of a right circular cone becomes a sector of a circle, and its area = 1/2 slant height X perimeter of base.

31. If a is the radius of a sphere, then

(i) volume of sphere = \(\pi a^3/3\);

(ii) surface of sphere = \(4\pi a^2\) or curved surface of circumscribing cylinder.

The first of these is a particular case of the prismatic formula (§ 58). To obtain (i) and (ii) together, we show that the volume of a sphere is proportional to the volume of the cube whose edge is equal to the radius of the sphere; denoting by S the surface of the sphere is \(2\pi a^2\), and hence, by taking two concentric spheres (cf. § 28), the area of the sphere is \(3\pi a^2\). This surface may be split up into elements, each of which is equal to a corresponding element of the curved surface of the circumscribing cylinder, so that \(3\pi a^2\)-curved surface of cylinder = \(2\pi a^2\) + \(4\pi a\). Hence \(\pi a^3\).

The total surface of the cylinder is \(4\pi a^2 + 2\pi a r + 2\pi a^2\), and its volume is \(\pi a^2 h\).

Hence

volume of sphere = \(4\pi a^2\) or volume of circumscribing cylinder;

surface of sphere = \(4\pi a^2\) or surface of circumscribing cylinder.

These latter formulae are due to Archimedes.

32. Moments and Centroids.—For every material body there is a point, fixed with regard to the body, such that the moment of the body with regard to any plane is the same as if the whole mass were collected at that point; the moment of each element of mass of the body by its distance from the plane. This point is the centroid of the body.

The ideas of moment and of centroid are extended to geometrical figures, whether solid or plane. The moment of a figure with regard to a plane is found by dividing the figure into elements of volume, area or length, multiplying each element by its distance from the plane, and adding the products. In the case of a plane area or line, the centroid of a figure to a straight line in the plane is the same as the moment with regard to a perpendicular plane through this line; i.e. it is the sum of the products of each element of area or length by its distance from the straight line. The centroid of a figure is a point fixed with regard to the figure, and such that its moment with regard to any plane (or, in the case of a plane area or line, with regard to any line in the plane) is the same as if the whole area, volume or length were concentrated at this point. The centroid is sometimes called the centre of volume, centre of area, or centre of arc. The proof of the existence of the centroid of a figure is the same as the proof of the existence of the centre of gravity of a body. (See Mechanics.)
where \( x \) = the distance between the two lines = \( N_x N_a \). These formulae also hold for converting moments of a solid figure with regard to a plane into moments with regard to a parallel plane through the centroid; \( x \) being the distance between the two planes. A line through the centroid of a solid figure is called a central line, and the plane through the centroid of a solid figure is a central plane, of the figure.

The centroid of a rectangle is its center, i.e., the point of intersection of its diagonals. An infinite area such as that of the disk of the figure is a central line, and a plane through the centroid of a solid central plane, of the figure. The line through the centroid of a solid figure may be determined by dividing the area into elementary strips by a series of parallel lines indefinitely close together, and concentrating the area of each strip at its centroid. Similarly the first moment of a solid figure may be obtained by dividing the figure into elementary prisms by two sets of parallel planes, and concentrating the volume of each prism at its centroid, with regard to which the moments are taken.

33. Solids and Surfaces of Revolution.—The solid or surface generated by the revolution of a plane closed figure or a plane continuous line about a straight line in its plane, not intersecting it, is a solid of revolution or surface of revolution, the straight line being its axis. The revolution need not be complete, but may be through any angle.

The section of a solid of revolution by a plane at right angles to the axis is an annulus or a sector of an annulus (fig. 5), or is composed of two or more such figures. If the solid is divided into elements by a series of such planes, and if \( h \) is the distance between two consecutive plane elements whose area is \( A \), then, if \( B \) is the volume of the element between these planes, when \( h \) is very small, is approximately \( h \times A \times \pi = k_{OB} \times \pi \). The corresponding element of the revolving figure is a rectangle of area \( h \times A \), and \( B \) is the total distance of the centroid of the annulus from the axis. Hence the total volume of the solid is \( M \times \pi \), where \( M \) is the sum of the quantities \( h \times A \). The volume of the figure with regard to the axis. The volume is therefore \( V \), where \( S \times \pi \) is the area of the revolving figure, and \( \pi \) is the distance of its centroid from the axis.

Similarly a surface of revolution can be divided by planes at right angles to the axis into elements, each of which is approximately a section of a surface of a right circular cone. By regarding each such element (§ 30) into a sector of a circular annulus, it will be found that the total area of the surface is \( M \times \pi \times L \).\( ^{2} \pi \), where \( M \) is the moment of the original curve with regard to the axis, \( L \) is the total length along the axis, and \( \pi \) is the distance of the centroid of the curve from the axis. These two theorems may be stated as follows:

(i) If any plane figure revolves about an external axis in its plane, the volume of the solid generated by the revolution is equal to the product of the area of the figure and the distance travelled by the centroid of the figure.

(ii) If any line in a plane revolves about an external axis in the plane, the area of the curved surface generated by the revolution is equal to the product of the length of the line and the distance travelled by the centroid of the line.

These theorems were discovered by Pappus of Alexandria (c. A.D. 300), and were made generally known by Guidinus (c. A.D. 1640). They are sometimes known as Pappus's Theorems, but are more properly described as the Theorems of Pappus. The theorems are of use, not only for finding the volumes or areas of solids or surfaces of revolution, but also, conversely, for finding centroids or centres of gravity of solid figures. They may be applied, for instance, to finding the centroid of a semicircle or of the arc of a semicircle.

34. Segment of Parabola.—The parabola affords a simple example of the use of infinitesimals. Let \( \Delta \) (fig. 6) be any arc of a parabola; and suppose we require the area of the figure bounded by this arc and the chord \( \Delta \).

Draw the tangents at \( A \) and \( B \), meeting at \( T \); draw TV parallel to the arc of the parabola, meeting \( \Delta \) in \( C \) and \( D \); and draw the tangent at \( C \), meeting AT and BT in \( a \) and \( b \). Then (see III), \( \Delta \) is equal to the area \( \Delta \) of the triangle \( TVC \), and \( AB = a + b \). Alternatively, the area \( \Delta \) of the triangle \( AB \) is \( \Delta KL \). TV = KL \( \times CV \); and the area of the figure bounded by \( AK, BL \) and the arc \( \Delta \), is

\[
\Delta KL \times \frac{1}{2} (AK + BL) + \Delta KL \times CM - \Delta KL \times (AK + BL) = \Delta KL \times (AK + BL - CM).\]

Similarly, for a corresponding figure \( K'L'BA \) outside the parabola, the area is

\[
\Delta K'L' \times \frac{1}{2} (K'A + 4MC + L'B).\]

35. The Ellipse and the Ellipsoid.—For elementary mensuration the ellipse is to be regarded as obtained by projection of the circle, and the ellipsoid by projection of the sphere. Hence the area of an ellipse whose axes are \( a \) and \( b \), and the volume of an ellipsoid whose axes are \( a, b, \) and \( c \), is \( \pi a b \). The area of a strip of an ellipse between two lines parallel to an axis, or the volume of the portion of the ellipsoid of an ellipse between two planes parallel to a principal section, may be found in the same way.

36. Examples of Applications.—The formulae of § 24 for the area of a trapezoid are of special importance in land-surveying. The measurements of a polygonal field or other area are usually taken as in § 25 (i); a diagonal \( AE \) is taken as the base-line, and for the points \( B, C, D, \ldots \) there are taken the distances \( AN, AP, AQ, \ldots \) along the base-line, and the lengths and directions of the offsets \( NB, PC, QD, \ldots \).

The area is then given by the formula of § 25 (ii).

37. The mensuration of earthworks involves consideration of quadrilaterals whose dimensions are given by special data, and of those sections which are such quadrilaterals. In the ordinary case three of the four lateral surfaces of the prismoid are inclined to the base.

In general, the area \( A = \frac{1}{2} (h \cot \psi + h) \), where \( h \) is the distance, measured at right angles to \( BC \), from the middle point of \( BC \) to \( AD \). Also, let \( ABC = r - \theta \), angle \( BCD = -\theta \), angle between \( BC \) and \( AD = \psi \). Then (as the difference of two triangles) the area \( ABCD = \frac{1}{2} (h \cot \psi + h - h \cot \psi - a) = \frac{1}{2} (h - a) \cot \theta \).

38.8. (A) Preliminary.—In § 24 the area of a right trapezoid has been expressed in terms of the base and the two sides; and in § 34 the area of a somewhat similar figure, the top having been replaced by an arc of a parabola, has been expressed in terms of its base and of three lengths which may be regarded as the sides of two separate figures of which it is composed. We have now to consider the extension of formulæ of this kind to other figures, and their application to the calculation of moments and volumes.

39. The plane figures with which we are concerned come mainly under the description of graphs of continuous variation. Let \( E \) and \( F \) be two magnitudes so related that whenever \( F \) has any value (within certain limits) \( E \) has a definite corresponding value. Let \( u \) and \( x \) be the numerical expressions of the magnitudes of \( E \) and \( F \). On any line \( OK \) take a length \( ON \) equal to \( u \) and, from \( N \) draw NP at right angles to \( OK \) and equal to \( h \); and \( H \) being convenient units in length. Then we may, ignoring the units that \( G \) is a graph of \( E \) on the \( NP \) being equal to \( x \) and \( u \) respectively. Let \( K \) and \( L \) be the positions of \( NP \) corresponding to the extreme values of \( x \). Then the different positions of \( NP \) will (if \( x \) may have any value from \( OK \) to \( OL \)) trace a curve on base \( KL \), and extending from \( KA \) to \( LB \), this is called the graph of \( E \) in respect of \( F \). The term is also sometimes applied to the line \( AB \) along which the point \( P \) moves as \( N \) moves from \( K \) to \( L \).

To illustrate the importance of the mensuration of graphs, suppose that we require the average value of \( x \) with regard to \( x \). It may be shown that this is the same thing as the mean distance.
MENSURATION

of elements of the graph from an axis through O at right angles to OX. Its calculation therefore involves the calculation of the area and the first moment of the graph.

40. The processes which have to be performed in the mensuration of figures of this kind are in effect processes of integration; the distinction between mensuration and integration lies in the different natures of the data. If, for instance, the graph were a trapezium, the calculation would proceed as follows: the area is expressed in terms of the $x$ coordinate from $x=a$ to $x=b$, of an expression of the form $px+q$. This would involve $p$ and $q$; but, for our purposes, the data are the sides $ps+q$ and $pb+q$ and the base $b-a$, and the expression of the integral is regarded as a trapezette.

The province of mensuration is to express the final result of such an elimination in terms of the data, without the necessity of going through the intermediate processes.

41. Trapezettes.—A figure of the kind described in § 39 is called a trapezette. A trapezette may therefore be defined as a plane figure bounded by two straight lines, a base at right angles to them, and a top which may be of any shape but is such that every ordinate from the base cuts it in one point and one point only; or, alternatively, it may be defined as the figure generated by an ordinate which moves in a plane so that its foot is always on a straight base to which the ordinate is at right angles, the length of the ordinate varying in any manner as it moves. The distance between the two straight sides, i.e., between the initial and the final position of the ordinate, is the breadth of the trapezette. Any line drawn from the base, at right angles to it, and terminated by the top of the trapezette, is an ordinate of the figure. The trapezium is a particular case. Edges and ordinate are then identical and the ordinate through any one point of that case, meets the base at that extremity. Any plane figure might be converted into an equivalent trapezette by an extension of the method of § 25 (iv).

42. A convex or solid figure, in its most general form, is such as would be constructed to represent the relation of a magnitude $E$ to two magnitudes $F$ and $G$ of which it is a function; it would stand on a plane base, and be comprised within a cylindrical boundary whose bases are parallel to the base. We may consider it as composed of figures of this general kind, but only with cases in which the base is a rectangle. The figure is such as would be produced by removing a piece of a rectangular prism, and is called a briquette. A briquette may be defined as the figure into which a pair of parallel planes, another pair of parallel planes at right angles to these, a base at right angles to these four planes (and therefore rectangular), and a top which is a surface of any form, but such that every ordinate from the base cuts it in one point and one point only. If a motion is generated as an ordinate with a fixed direction at right angles to itself and changing its breadth unaltered, or by an ordinate moving so that its foot has every possible position within a rectangular base.

43. Ordinates in a Trapezette.—An edge of the trapezette will be denoted by $u$, and the abscissa of this ordinate, i.e., the distance of its foot from a certain fixed point or origin $O$ on the base (or the base produced), will be denoted by $x$, so that $u$ is some function of $x$. The bounding ordinates of the trapezette are the bounding ordinates of the trapezette in its present position with regard to its breadth $b$. The circle, for instance, is regarded geometrical as a line described in a particular way, while from the point of view of mensuration it is a figure of a particular shape. Similarly, analytical plane geometry describes a curve as lying in a plane in a particular way, while analytical plane mensuration deals with the figure generated by an ordinate moving so that its length varies in a particular manner depending on its position.

44. Some cases in which the figure in three dimensions, analytical geometry is concerned with the form of the surface, while analytical mensuration is concerned with the figure as a whole. The graph of a plane figure is such that the solid extends from one to the other of these planes. The section by any intermediate parallel plane will be called a "cross-section." The solid may then be regarded as generated by the cross-section moving parallel to itself, and rolling with its cross-section on a plane. The section by a fixed plane is a curve whose equation is $y=f(x)$.

47. The statement that the ordinate $u$ is a function of the abscissa $x$, or that $u=f(x)$, must be distinguished from $u=f(x)$ as the equation to the top of the trapezette.

48. Representation of Volume by Area.—An important plane graph is that which represents the volume of a solid figure. Suppose that we take a plane figure (parallel planes) so that the solid can be expressed in terms of the length of the ordinate $b$. Then the area in a similar manner depending on its position.

4.4. The cross-section at distance $x$ from the plane $A$. On a straight line $OX$ in any plane take a point $N$ at distance $x$ from $O$, and draw an ordinate $NQ$ at right angles to $OX$ and extended $b$ to $H$, where the fixed length (e.g., the unit of measurement). If this is done for every possible value of $x$, there will be a series of ordinates tracing out a trapezette with base along $OX$. The volume comprised between the cross-section whose area is $S$ and a consecutive cross-section at distance $y$ from it is ultimately $S\theta$, where $\theta$ is indifferently small; and the area between the corresponding ordinates of the trapezette is $(S\theta)\theta=0$. Hence the area of each element of the solid figure is to be found by multiplying the area of the corresponding element of the trapezette by $\theta$, and the total volume is $S\theta$ times.
The volume of a briquette can be found in this way if the area of the section by any principal plane can be expressed in terms of the distance of this plane from a fixed plane of the same set. The result of treating this area as if it were the ordinate of a trapezette leads to special formulae, when the data are of the kind mentioned in § 44.

49. (B) Mensuration of Graphs of Algebraical Functions.—The first class of cases to be considered comprises those cases in which $u$ is a single-valued, real, and, as between the mid-ordinates of the strips, the series being taken up to $b^2u_1 + \alpha_b^2u_1$ at least, where $u$ is of degree $2f$ or $2f + 1$ in $x$. Thus we find from (i) that Simpson’s second formula, for the case where the top is a parabola (with axis, as before, at right angles to the base) and there are three strips of breadth $h$, may be replaced by

$$\text{area} = \frac{h}{3}(3u_1 + 2u_2 + \mu_1).$$

This might have been deduced directly from Simpson’s first formula, by a series of eliminations.

50. Hence, for the case of a parabola, we can express the area in terms of the bounding ordinates of two strips, but, if we use Simpson’s formulae for strips, so that, in each case, three ordinates are required. The question then arises whether, by removing the limitation as to the position of the ordinates, we can reduce their number.

51. In fig. 4 (§ 54) we draw ordinates OD midway between KA and MB, and KE midway between MB and LB, meeting the top in D and E (fig. 8), and join DE, meeting KA, LB, and MB in H, J, and W. Then it may be shown that DE is not a trapezette and that the area of the figure between chord DE and arc DE is half the sum of the areas DHA and EJB. Hence the area of the right trapezette $\text{KACB}$ is greater than the area of the trapezette $\text{KACB}$. If we were to take OD close to MB, the former area would be still greater. If, on the other hand, we were to make them very close to KA and LB respectively, the area of the trapezette would be the greater. There is therefore some intermediate position such that the two areas are equal and that the area of the trapezette is represented by $KL \cdot \frac{1}{2}(OD + RE)$.

52. To find this position, let us write $OM = MR = \theta$, KM. Then $\text{WC} = \theta^2$, $\text{VC} = (1 - \theta^2) \text{VC}$; the curved area $\text{ABC}$ is parallellogram $\text{AFGB} = \text{KLC}$, VC; parallellogram $\text{ABF} = \text{KL}$, $\text{VC} = (1 - \theta^2) \text{KL}$, VC. Hence the areas of the trapezette and of the trapezium will be equal if.

$$1 - \theta^2 = \frac{1}{3}, \theta = 1/\sqrt{3}.$$ This value of $\theta$ is the same for all parabolas which pass through D and E and have their axes at right angles to KL. It follows that, by taking two ordinates in a certain position with regard to the bounding ordinates, the area of any parabolic trapezette whose top passes through these two will be expressed in terms of those ordinates and of the breadth of the trapezette.

53. The same formula will also hold (§ 52) for any cubic trapezette through the points OA.

54. As a particular case of a general theorem, due to Gauss, that if $u$ is an algebraical function of $x$ of degree $2p$ or $2p + 1$, the area can be expressed in terms of $p + 1$ ordinates taken in suitable positions.

55. The Prismatical Formula.—It follows from §§ 48 and 51 that, if $V$ is a solid figure extending from a plane K to a parallel plane L, and if the area of every cross-section parallel to these planes is a quadratic function of the distance of the section from a fixed plane parallel to them, Simpson’s formula may be applied to find the volume of the solid. If the areas of the two ends in the planes K and L are $S_0$ and $S_1$, and the area of the mid-section (i.e. the section by a plane parallel to these planes and midway between them) is $S_h$, the volume is $\frac{h}{3}(S_0 + 2S_h + S_1)$, where $h$ is the total breadth.

This formula applies to two cones, the cone, the sphere, the ellipsoid and the prismoid. In the case of the sphere, for instance, whose radius is $R$, the area of the section at distance $x$ from the centre is $x^2 + x^2$, which is a quadratic function of $x$; the values of the ordinates are $0$, $W$, and $0$, and the volume is therefore $\frac{1}{2} \cdot 2 \pi R^3 = \pi R^3$.

To show that the area of a cross-section of a prismoid is of the form $ax^2 + bx + c$, where $x$ is the distance of the cross-section from one end, we may proceed as in § 27. In the case of a pyramid, of height $h$, the area of the section by a plane parallel to the base and at distance $x$ from the vertex is clearly $x^2h^2/2$ area of base. In the case of a wedge with parallel ends the rate of increase of the area is placed by $x/h$. For a tetrahedron, two of whose opposite edges are AB and CD, we require the area of the section by a plane parallel to AB and CD be $h$, and let a plane at distance $x$ from the plane through AB cut the edges AC,
MENURATION

BC, BD, AD, in P, Q, R, S (fig. g). Then the section of the pyramid by this plane is the parallelogram PQRS. By drawing AC and AD parallel to BC and BD, so as to meet the plane through CD in c and d, and producing QP and RS to meet AC and AD in q and d, the areas can be found, in position to one another, by the formula cCd; this is also a quadrature function of x. The proposition can therefore be established for a prism generally by the method of § 27 (iv).

The formula is known as the prismoidal formula.

By 27, the point of multi-point or any ordinate are at an equal distance from the axes of u, it is easily shown that the first moment (with regard to this axis) of a trapezoid whose ordinate is u is equal to the area of a trapezoid whose ordinate is xu; and this area can be found by the methods of the preceding sections in cases where u is an algebraic function of x. The formulae can then be applied to finding the moments of certain volumes.

In the case of the parabolic trapezoid, for instance, xx is of degree 2 in x, and therefore the first moment is |\( \int (a^2x + b + c)x^2 dx \)|.

Then, by means of any solid whose cross-section at distance x from the plane of the face is a trapezoid whose ordinate is y, the position of the cross-section through the centroid is to be found by determining the position of the centre of gravity of particles of masses proportional to |\( \int (a^2x + b + c)x^2 dx \)|, and 4 (x) placed at the extremities and at the centre of its axis; i.e. the centroid is at distance |\( \frac{1}{2} x \)| from the plane face.

60. The method can be extended to finding the second, third, ..., moments of a trapezoid with regard to the axis of u. If u is an algebraic function of x, the degree of which is p, so that the ordinate of a trapezoid, for which the ordinate y is of degree not exceeding \( p + q \), may be expressed by a formula |\( \int (a^2x + b + c)x^2 dx \)|, which contains the first moment of the trapezoid, the qth moment of the trapezoid, and the mean value of \( x^2 \).

The calculation of this last expression is simplified by noticing that we have, for equal ordinates, the ratios of \( a^2, \), and of \( a^2, \) not with their actual values.

61. Cubature of a Briquette.—To extend these methods to a briquette, where the ordinate is u an algebraic function of x and y, the area y=0, being parallel to the sides of the base, we consider that the area of a section at distance x from the plane b is expressed in terms of the ordinates in which it intersects the series of planes, parallel to \( y=0 \), through the given ordinates of the briquette (§ 44); and that the area of the section is then represented by the ordinates of the figure referred to the ordinates of the plane a.

Suppose, for instance, that u is of degree not exceeding 3 in x and of degree not exceeding 3 in y, i.e., that it contains terms in \( x^3 y, x^2 y^2, \) etc.; and suppose that the edges parallel to which x and y are measured are of lengths 2h and \( h, \) the briquette being divided into six elements by the plane \( y=0+t \), and the planes \( y=0-t \), and that the 12 ordinates forming the edges of these six elements are to be considered, the area of the plane \( y=0 \), and of the section by the plane \( y=0+t \), may be found by Simpson’s second formula; call these \( A_1 \) and \( A_4 \). The area of the section by a plane at distance x from the edge \( x=0 \) is a function of x whose degree is the same as that of u. Hence Simpson’s formula applies, and the volume is |\( \int \frac{1}{2}(A_1 + A_4)dx \)|.

The process is simplified by writing down the general formula for u, and substituting the values of u. The formula, in the above case, is

|\( \frac{1}{2} \int (u_0 + 3u_1 + 3u_2 + u_3) + 4x |\( \int (u_0 + 3u_1 + u_2) + \frac{1}{2} (u_0 + 3u_1 + u_2) dx \)|.

Here \( u, rubbed \) denotes the ordinate for which \( x=0 \) th, y=xy, and \( \phi \) the result is the same if we multiplied by \( \frac{1}{2} (u_0 + 3u_1 + 3u_2 + u_3) + 4x |\( \int (u_0 + 3u_1 + u_2) + \frac{1}{2} (u_0 + 3u_1 + u_2) dx \)|.

62. The area is a particular case of a general principle that the obtaining of an expression such as |\( \int (u_0 + 3u_1 + u_2) + \frac{1}{2} (u_0 + 3u_1 + u_2) dx \)| or |\( \int (u_0 + 3u_1 + 3u_2 + u_3) + 4x |\( \int (u_0 + 3u_1 + u_2) + \frac{1}{2} (u_0 + 3u_1 + u_2) dx \)| may be obtained by means of the ordinates of the figure formed by joining the points of the trapezoid whose area is \( k_1 y + k_2 x + \ldots + k_{n-1} y_{n-1} + k_n y_0 \), which is called the trapezoidal area, and will be denoted by C1. If the data are \( u_0, u_1, \ldots, u_n \), we can form a series of trapezia by drawing the tangents to the extremities of these ordinates; the sum of the areas of these trapezia will be |\( \int (u_0 + u_1 + u_2 + \ldots + u_n) dx \)|. This is called the tangential area, and will be denoted by T1. The
MENSURATION

143

tangential area may be expressed in terms of chordal areas. If we write
C imaginary for the chordal area obtained by taking ordinates at
intervals 2h, then T1 = 2C1 - C. If the trapezette, as seen from above,
everywhere convex or everywhere concave, the true area lies
between C1 and T1.

68. Other Rules for Trapezettes.—The extension of this method
consists in dividing the trapezette into minor trapezettes, each
consisting of two or more strips, and replacing each of these minor
trapezettes by a new figure, whose ordinate v is an algebraical function
of x; this function being chosen so that the new figure shall
coincide with the original figure so far as the given ordinates are
concerned. This means that, if the minor trapezette consists of k
strips, the ordinate of k - 1 in x, according as the data are the
bounding ordinates or the mid-ordinates, if A denotes the true
area of the original trapezette, and B the aggregate area of the
substituted figures, we have A \(\neq\) B, where \(\neq\) denotes approximate
equality. The value of B is found by the methods of \(\S\) 49-55.
The following are some examples.

(i) Suppose that the bounding ordinates are given, and that \(m\)
is a multiple of 2. Then we can take the strips in pairs, and treat each
pair as a parabolic trapezette. Applying Simpson’s formula to each
of these, we have

\[ A \approx \frac{1}{3} \left( y_0 + 4y_1 + 2y_2 + 4y_3 + 2y_4 + \ldots + 2y_{m-1} + 4y_m + y_{m+1} \right) \]

This is Simpson’s rule.

(ii) Similarly, if \(m\) is a multiple of 3, the repeated application of
Simpson’s second formula gives Simpson’s second rule

\[ A \approx \frac{1}{3} \left( y_0 + 3y_1 + 3y_2 + 2y_3 + 3y_4 + 2y_5 + \ldots + 3y_{m-2} + 2y_{m-1} + 3y_m \right) \]

(iii) If mid-ordinates are given, and \(m\) is a multiple of 3, the repeated
application of the formula of \(\S\) 55 will give

\[ A \approx \frac{1}{3} \left( y_0 + 3y_1 + 3y_2 + 2y_3 + 3y_4 + 2y_5 + \ldots + 3y_{m-2} + 2y_{m-1} + 3y_m \right) \]

69. The formulae become complicated when the number of strips
in each of the minor trapezettes is large. The method is then modified
by reducing the expression which gives the area of the sub-
stituted figures approximately. This introduces a further inaccuracy;
but this latter may be negligible in comparison with the main in-
accuracies already involved (cf. \(\S\) 20 (iii)).

Suppose, for instance, that \(m\) is even, and that we consider the
trapezette as a whole; the data being the bounding ordinates.
Since there are seven of these, \(v\) will be of degree 6 in \(x\); and we shall
have (if 54 (i))

\[ B = \frac{1}{6} \left( y_0 + 3y_1 + 3y_2 + 2y_3 + 3y_4 + 2y_5 + \ldots + 3y_{m-2} + 2y_{m-1} + 3y_m \right) \]

If we replace \(\frac{1}{6} \left( y_0 + 3y_1 + 3y_2 + 2y_3 + 3y_4 + 2y_5 + \ldots + 3y_{m-2} + 2y_{m-1} + 3y_m \right)\) in this expression by \(\frac{1}{6} \left( y_0 + 3y_1 + 3y_2 + 2y_3 + 3y_4 + 2y_5 + \ldots + 3y_{m-2} + 2y_{m-1} + 3y_m \right)\), the method of
\(\S\) 68 gives

\[ A \approx \frac{1}{3} \left( y_0 + 3y_1 + 3y_2 + 2y_3 + 3y_4 + 2y_5 + \ldots + 3y_{m-2} + 2y_{m-1} + 3y_m \right) \]

\[ \text{where P, Q, R, ... satisfy the k equations} \]
\[ P + Q + R + \ldots = 0, \quad P^2 + Q^2 + R^2 + \ldots = 0, \quad \ldots \]

The last \(k - 1\) of these equations give

\[ \frac{1}{1} / = 1, \quad \frac{1}{2} / = 1, \quad \ldots = 0, \quad \ldots \]

\[ \frac{1}{k-1} / = 1, \quad \frac{1}{k} / = 0, \quad \ldots = 0, \quad \ldots \]

Combining this with the first equation, we obtain the values of
P, Q, R, ... The same method applies for tangential areas, by taking

\[ A \triangleq PT_1 + QT_1 + RT_1 + \ldots \]

provided that p, q, r, ... are odd numbers.

70. The justification of the above methods lies in certain properties
of the series of successive differences of \(u\). The fundamental
assumption is that each group of strips of the trapezette may be
replaced by a figure for which differences of \(u\), above those of a
certain order, vanish (\(\S\) 54). The legitimacy of this assumption, and
of the further assumption which enables the area of the new
figure to be expressed by an approximate formula instead of by an
exact formula, must be verified in every case by reference to the
actual differences.

71. Correction by means of Extreme Ordinates.—The preceding
methods, though apparently simple, are open to various objections
in practice, such as the following: (i) The assignment of different
coefficients of different ordinates, and even the selection of ordinates
for the purpose of finding \(C_1, C_2, \ldots, C_n\) (\(\S\) 70), is troublesome. (ii) This
assignment of different coefficients means that different weights are
given to different ordinates; and the relative weights may not
agree with the relative accuracies of measurement. (iii) Different
formulae have to be adopted for different values of \(m\); the method
is therefore unsuitable for the construction of a table giving successive
values of the area under successive strips. (iv) In order to find
what formula may be applied, it is necessary to take the successive
differences of \(u\); and it is then just as easy, in most cases, to use
a formula which directly involves these differences and therefore
shows the degree of accuracy of the approximation.

The alternative method, therefore, consists in taking a single
formula, such as the trapezoidal rule, and correcting it to suit the
mutual relations of the differences.

To illustrate the method, suppose that we use the chordal area
\(C_1\), and that the trapezette is in fact parabola. The difference
between \(C_1\) and the true area is made up of a series of areas bounded
by chords and arcs; this difference becoming less as we subdivide
the figure into a greater number of strips.

The fact that \(C_1\) does not give the true area is due to the fact that
in passing from one extremity of the top of any strip to the other
extremity the tangent to the trapezette changes its direction. We
have therefore in the first place to see whether the difference can be
described in terms of the directions of the tangents.

Let \(KAB\) (fig. 10) be one of the strips, of length \(h\). Draw the
tangents to the curve at \(A\) and \(B\), meeting at \(T\); and through \(T\) draw
a line parallel to \(KA\) and \(LB\), meeting the arc \(AB\) in the chord \(AB\) in \(V\).
Draw \(AD\) and \(BE\) perpendicular to this line, and \(DF\) and \(TG\) perpendicular to \(VB\).
Then \(AD = EB = I,\) and the triangles

\[ A \triangleq \text{AVD and BVE are equal.} \]

The area of the trapezette is less (in
fig. 10) than the area of the trapezium \(KAB\) by two-thirds of the area of
the triangle \(ATB\) (\(\S\) 34). This latter area is

\[ \text{area of the trapezium} = h^2 \tan \theta \]

Hence, if the angle which the tangent at the extremity of the ordinate
\(x\) makes with the axis of \(x\) is denoted by \(\psi\), we have
area from \(x_0\) to \(x_1\) = \(\frac{1}{2} h^2 \tan \theta \psi_1 - \\tan \psi\),
area from \(x_1\) to \(x_2\) = \(\frac{1}{2} h^2 \tan \theta \psi_2 - \\tan \psi\),
and hence, by summation,

\[ A = C_0 - 2h^2 \tan \psi \tan \theta \psi \tan \theta \psi \]

This, in the notation of \(\S\) 46 and 54, may be written

\[ A = C_0 + \frac{1}{2} h^2 \tan \theta \psi \tan \theta \psi \tan \theta \psi \]

Since \(h = H/m\), the inaccuracy in taking \(C_1\) as the area varies as
1.\(h^2\).

It might be shown in the same way that

\[ A = T_1 + \frac{1}{2} h^2 \tan \theta \psi \tan \theta \psi \tan \theta \psi \]

Their generalization is given by the Euler-Maclaurin formula
MENSURATION

81. There is, however, a certain set of cases, occurring in statistics, in which the data are not a series of ordinates, but the areas \( A_1, A_2, \ldots, A_m \) of the strips bounded by the consecutive ordinates \( u_0, u_1, \ldots, u_m \). The determination of the moments in these cases involves special methods, which are considered in the next two sections.

82. The most simple case is that in which the trapezette tapers out in such a way that the curve forming its top has very close contact, at its extremities, with the base; in other words, the differential coefficients \( u', u'', u''' \), etc., are practically negligible for \( x = 0 \) and for \( x = x_m \). The method adopted in these cases is to treat the areas \( A_1, A_2, \ldots, A_m \), as if they were ordinates placed at the points for which \( x = x_1, x = x_2, \ldots, x = x_m \), to calculate the moments on this assumption, and then to apply certain corrections. If the first, second, \( \ldots, m \) moments, so calculated, before correction are denoted by \( p_1, p_2, \ldots, p_m \), we have

\[
p_1 = x_1 A_1 + x_2 A_2 + \ldots + x_m A_m - \pi^2 A_1 - \ldots - A_m - \pi^2 A_1 - A_2 - \ldots - A_m \ldots
\]

These are called the raw moments. Then, if the true moments are denoted by \( \mu_1, \mu_2, \mu_3, \ldots \), and if \( u_m \) is the total area \( A_1 + A_2 + \ldots + A_m \), the general expression being

\[
x^2 \mu'_2 = \frac{\pi^2}{2} + \frac{\pi^2}{2} \mu_2 - \mu_3 \ldots
\]

The position of the central ordinate is given by \( x = m/2 \mu_2 \), and is therefore given approximately by \( x \approx p_1/\mu_2 \). To find the moments with regard to the central ordinate, we must use this approximate value, and transform by means of the formulae given in \( \S \, 32 \). This can be done either before or after the above corrections are made. If the transformation is made first, and if the resulting raw moments with regard to the (approximate) central ordinate are \( p_1, p_2, \ldots, p_m \), the true moments \( \mu_1, \mu_2, \mu_3, \ldots \), with regard to the central ordinate are given by

\[
\mu_1 = \mu_2 = \mu_3 = \ldots
\]

The establishment of these formulae involves the use of the integral calculus.

The shape and position of the trapezette is defined by the ordinates of its sides, i.e., the differences \( \Delta x, \Delta y \), of the points, \( \Delta x = x_{n+1} - x_n, \Delta y = y_{n+1} - y_n \), respectively. An alternative method, which in some ways preferable, is to complete the table of differences by repeating the differences of the highest order that will be taken into account (see INTERPOLATION), and then to use central-difference formulae.

The determination of the corrections in respect of the terms shown in square brackets in the formulae of \( \S \, 75 \), certain ordinates other than those used for \( A_1, A_2, \ldots, A_m \), are sometimes found specially. For instance, \( \mu_2 \) may be found by taking differences or values of \( A_1, A_2, \ldots, A_m, \ldots \) only in the case of special values of the integral calculus.

The expression for the form \( x^m \mu'_m(x) \), when \( \phi(x) \) is a definite function of \( x \), and the conditions with regard to \( u \) are the same as in \( \S \, 82 \).

(i) If \( \phi(x) \) is an explicit function of \( x \), we have

\[
\int x^m \mu'_m(x) dx = \int A_1 \phi(x) + A_2 \phi(x) + \ldots + A_m \phi(x) + \ldots
\]

where \( \psi(x) \equiv \phi(x) - \frac{\mu_2}{2!} \phi''(x) + \frac{\mu_3}{3!} \phi'''(x) - \frac{\mu_4}{4!} \phi''''(x) + \cdots \).

The coefficients \( \lambda_1, \lambda_2, \lambda_3, \ldots \), have the values given in \( \S \, 82 \).

(ii) If \( \phi(x) \) is not given explicitly, but is tabulated for the values \( x_1, x_2, \ldots, \) of \( x \), the formula of (i) applies, provided we take

\[
\psi(x) \equiv \int \left( x^m \mu'_m(x) - \frac{\mu_2}{2!} \phi''(x) + \frac{\mu_3}{3!} \phi'''(x) - \frac{\mu_4}{4!} \phi''''(x) + \cdots \right) \phi(x)
\]

The formula can be adapted to the case in which \( \phi(x) \) is tabulated for \( x = x_m \), \( x = x_{m-1} \), \( x = x_{m-2} \), \ldots

84. In cases other than those described in \( \S \, 82 \), the 7th moment with regard to the axis of \( u \) is given by

\[
\mu'_7 = \int x^7 \mu'_7(x) dx = A \Phi(x_m) - T,
\]

where \( A \) is the total area of the original trapezette, and \( S_{m+1} \) is the area of a trapezette whose ordinates at successive horizontal distances \( A \), beginning and ending with the bounding ordinates, are \( x^m A_1, x^{m-1} A_2, \ldots, x A_m, A_{m+1} \). The value of \( S_{m+1} \) has to be found by a quadrature-formula. The generalized formula is

\[
\int x^m \mu'_m(x) dx = A \Phi(x_m) - T,
\]

**Moments of a Trapezette.**—The methods of finding the moments of a trapezette, when the data are a series of ordinates. To find the 7th moment when \( u_0, u_1, u_2, \ldots, u_m \), are given, we have only to find the area of a trapezoid whose ordinates are \( x^m u_0, x^{m-1} u_1, x^m u_2, \ldots, x u_m \).
where $T$ is the area of a trapezette whose ordinates at successive distances $h$ are $0, \Delta \phi(x_1), (\Delta \phi(x_2), \ldots, (\Delta \phi(x_n), \ldots)$; the accents denoting the first differential coefficient.

85. Moments and Areas of a Briquette.—The application of the methods of §§ 75–79 to calculation of the volume of a briquette leads to complicated formulae. If the conditions are such that the methods of § 61 cannot be used, $x$ and $y$ are undesirable as giving too much weight to particular ordinates. The best course is, therefore, to find the ordinates of the area of section at the end of § 48; i.e., to find the areas of one set of parallel sections, and treat these as the ordinates of a trapezette whose area will be the volume of the briquette. The data of the area of a briquette can be extended to the case of a briquette whose top has close contact with the base all along its boundary; the data being the volumes of the minor briquettes formed by the planes $x = x_0, x = x_1, \ldots, y = y_0, y = y_1, \ldots$. The method of constructing the formulae is explained in § 62. If we write

$$S_{x_0} = \int_0^L \int_0^{x_0} \int_0^y y \, du \, dx \, dy,$$

we first calculate the raw values $s_{0x}, s_{3x}, s_{4x}, \ldots, s_{0y}, s_{3y}, s_{4y}, \ldots$, on the assumption that the volume of each minor briquette is concentrated along its mid-ordinate ($\mathfrak{A}_4$), and we then obtain the formulae of correction by multiplying the formulae of $\mathfrak{A}_4$ in pairs. Thus we find (e.g.)

$$S_{x_0} = \sum_{s_{x_0}} + \sum_{s_{x^1}},$$

$$S_{x_0} = \sum_{s_{x_0}} + \sum_{s_{x^1}},$$

and $s_{x_0}$ is the total volume of the briquette.

86. The formulae of § 62 can be extended to the case of a briquette whose top has close contact with the base all along its boundary; the data being the volumes of the minor briquettes formed by the planes $x = x_0, x = x_1, \ldots, y = y_0, y = y_1, \ldots$. The method of constructing the formulae is explained in § 62. If we write

$$S_{x_0} = \int_0^L \int_0^{x_0} \int_0^y y \, du \, dx \, dy,$$

we first calculate the raw values $s_{0x}, s_{3x}, s_{4x}, \ldots, s_{0y}, s_{3y}, s_{4y}, \ldots$, on the assumption that the volume of each minor briquette is concentrated along its mid-ordinate ($\mathfrak{A}_4$), and we then obtain the formulae of correction by multiplying the formulae of $\mathfrak{A}_4$ in pairs. Thus we find (e.g.)

$$S_{x_0} = \sum_{s_{x_0}} + \sum_{s_{x^1}},$$

$$S_{x_0} = \sum_{s_{x_0}} + \sum_{s_{x^1}},$$

and $s_{x_0}$ is the total volume of the briquette.

87. If the data of the briquette are, as in § 86, the volumes of the minor briquettes, but the condition as to close contact is not satisfied, we have

$$\int_0^L \int_0^{x_0} \int_0^y y \, du \, dx \, dy = K + L + R - x_0^2 s_{x_0},$$

where $K$ is the $x_0$th moment with regard to plane $y = 0$, $L$ is the $x_0$th moment with regard to plane $x = 0$, and $R$ is the volume of a briquette whose ordinates at $x_0$ is found by multiplying by $y$ the $y_0$th moment with regard to plane $y = 0$ of the original briquette which lies between the planes $x = x_0, x = x_1, y = y_0, y = y_1, \ldots$. The ordinates of this new briquette at the points of intersection of $x = x_0, x = x_1, \ldots, y = y_0, y = y_1, \ldots$ are obtained from the data by summation of multiples of linear ordinate functions. The ordinary methods then apply for calculation of its volume. Either both or the expressions $K$ and $L$ will have to be calculated by means of the formula of § 84; if this is applied to both expressions, we have a formula which may be written in a more general form

$$\iint \iint \int_0^L \int_0^{x_0} \int_0^y y \, du \, dx \, dy \cdot \phi(b, g).$$

The second and third expressions on the right-hand side represent areas of trapezettes, which can be calculated from the data; and the fourth expression represents the volume of a briquette, to be calculated in the same way as $R$ above.

88. Cases of Failure.—When the sequence of differences is not such as to enable any of the foregoing methods to be applied, it is sometimes possible to go back to the data by measurement of the individual ordinates, and then apply a suitable method to the amplified series.

There is, however, a certain class of cases in which no subdivision of intervals will produce a good result; viz. cases in which the top of the figure is, at some point, an arbitrary chord of the boundary, right angles to the base. Euler's formula ($\mathfrak{S}_7$) assumes that the bounding values of $u$, $u''$, $\ldots$ are not infinite; this condition is not satisfied in the cases here considered. It is also clearly impossible to express $u$ as an algebraic intermediate function of $x$ and $y$ if some value of $du/dx$ or $dy$ is to be finite.

No completely satisfactory methods have been devised for dealing with these cases. One method is to construct a table for interpolation of $x$, $y$, $u$, and from this table to calculate values of $x$ corresponding to values of $u$, proceeding by equal intervals; a quadrature-formula can then be applied. Some points for interpolation then require the area of the trapezette $A$ in fig. 11; the curve being at right angles to the base $AL$ at $A$. If $QD$ is the bounding ordinate of $A$, and from one of the component strips, we can calculate the area of $QDBL$ in the ordinary way. The data for the area $A'Q$ are a series of values of $u$ corresponding to equidifferent values of $x$; if we denote by $y$ the distance of a point on the arc $AD$ from $Q$, we can from the series of values of $u$ construct a series of values of $y$ corresponding to equidistant values of $x$, and thus find the area of $ADQ$, treating $QD$ as the base. The process, however, is troublesome.

89. Examples of Quadrature-formulas.—The following are some examples of cases in which the above methods may be applied to the calculation of areas and integrals.

(i) Construction of Mathematical Tables.—Even when $u$ is an explicit function of $x$, so that $f(u)dx$ may be expressed in terms of $x$, it is often more convenient to use an approximate value of such an integral, to use finite-difference formulae. The formula of § 76 may (see Differences, Calculus of) be written

$$\int_0^L f(u) \, du = \mu_x + \frac{\mu_x}{2} + \frac{\mu_x}{3} + \ldots$$

The second of these is usually the more convenient. Thus, to construct a table of values for $\mu_x$, we may in the $x$th line, first form a table of values of $\mu_x$ for the intermediate values of $x$, from this obtain a table of values of $(1 + \frac{1}{2} x^3 + \frac{1}{3} x^3 + \ldots) \mu_x$ for these values of $x$, and then construct the table of $f(u)dx$ by successive additions. Attention must be given to the possible accumulations of small errors due to the approximation. The value of each of the above formulae involves an arbitrary constant; but this disappears when we start the additions from a known value of $\int_0^L f(u) \, du$.

The process may be repeated. Thus we have

$$\int_0^L f(u) \, du = (a + x + \frac{x^3}{3} + \frac{x^3}{3} + \ldots) \mu_x$$

Here there are two arbitrary constants, which may be adjusted in various ways.

The formulae may be used for extending the accuracy of tables, in cases where, if $r$ represents the quantity tabulated, $h\delta x/\delta y$ can be conveniently expressed in terms of $r$ and $x$ to a greater degree of accuracy than it could be found from the table. The process practically consists in using the table as it stands for the first or second differences of $r$ and then building up the table afresh.

(ii) Life Insurance.—The use of quadrature-formulae is important in actuarial work, where the fundamental tables are based on experience. The formulae applying these tables involve the use of the tabulated values and their differences.

90. The following are instances of the application of approximate formulae to the calculation of the volumes of solids.

Measure to find the volume of a sphere by a trapezoidal rule. The volume of a sphere of radius $a$ is

$$V = \frac{4}{3} \pi a^3.$$
MENZEWI—MENZEL, A. F. E. VON

(1903). For examples of measurement of areas by geometrical construction, see G. C. Turner, *Graphics applied to Arithmetic, Mensuration and Statics* (1907). Discussions of the approximate calculation of definite integrals will be found in works on the infinitesimal calculus; see e.g. E. W. Hobson, *A Course in Mathematical Analysis* (1905; trans. by E. R. Hedrick). For the methods involving finite differences, see references under DIFFERENCES, CALCULUS OF; and, interpolation. On calculation of moments of graphics, see W. H. Young and R. Courant, *Differential and Integral Calculus*. The formulae of §2, see also *Biomeirika*, v. 450. For mechanical calculation of areas and moments see *Calculating Machines.*

MENZEWI, a chain of islands in the Dutch East Indies, off the west coast of Sumatra, between 3° and 3° 30' S. There are twenty-one islands in all, of which the majority lie close to or between the four largest—Siherut, Sikaban or Sipora, North Pageh and South Pageh. The two last (also called Pagi or Poggy) are sometimes termed the Nassau Islands. The total area is 1224 sq. m. The islands are included in the administration of Padang, Sumatra. They are apparently volcanic. Coral reefs lie off the coasts and render them difficult of access. The natives in language and customs present affinities with some Polynesians, and have been held to be a survival of the eastward immigration of people of Caucasian stock which took place before those which established the "pre-Malay" peoples (such as the Dyaks and Battas) in the Malay Archipelago. The islands produce some coco-nuts, sago, trepang and timber.

MEMENTH, or MONTEITH, a district of south Perthshire, Scotland, roughly comprising the territory between the Teith and the Forth. Formerly it was a stewartry and gave the title to an earldom. The title was first held by Gilchrist, a Celtic chief ennobled by Malcolm IV., and passed successively to Walter Comyn (d. 1258), to a branch of the Stewarts, and finally to the Grasims, becoming extinct in 1694. The lake of Menteith, situated 23 m. S. of Loch Vennachar measures 13 m. long by 1 m. broad, and contains three islands. On Inchmahome (Gaelic, "the Isle of Rest") are the ruins of an Augustinian priory founded in 1258 by Walter Comyn. It is Early English, with an ornate western doorway. The body of Queen Mary, when a child of five, for a few months before her departure to France in 1548. On Inch Talla stands the ruined tower of the earls of Menteith, dating from 1428. The village of Port of Monteith (pop. of parish, 1088), on the north shore of the lake, is 3½ m. north by west of the station of the same name on the North British Railway Company's Forth & Clyde line.

MENONE (Fr. Menton), a town in the department of the Alpes Maritimes in south-east France, situated on the shore of the Mediterranean, about 15 m. by rail E. of Nice. Pop. (1901), 9494. It is built in the form of an amphitheatre on a rocky promontory, which divides its semicircular bay into two portions. The main town is composed of two parts. Below, along the seashore, is the town of hotels and foreigners, while above, and inaccessible to wheeled vehicles, is that of the native Mentonean, with steep, narrow and dark streets, clinging to the mountain sides around the strong castle and the difficult of access against pirates. In the old town is the church of St. Michel, rebuilt in great part since an earthquake in 1887, while below, in the principal street, the Corniche road, is the monument set up in 1866 to commemorate the union (in 1860) of Mentone with France. East of the main town is the suburb of Garavan, sheltered by cliffs, and filled with hotels. A mile and a half farther on is the Pont St Louis, which marks the frontier between France and Italy, while beyond it Sir Thomas Hanbury's villa at La Murtola is soon reached, with its marvellous gardens of 250 acres. West of the main town more hotels and villas are scattered along the coast towards Cap Martin. This is a pine-covered promontory which shelters the Bay of Mentone on the west, and is crowned by a great hotel, not far from which is the villa of the ex-empress Eugénie. Facing south-east, and sheltered on the north and west by mountains, the Bay of Mentone has a delicious climate and is frequented by invalids. The mean for the year is 6°F, while that for the winter is 72°F in the sun, and 55°F in the shade. Frost occurs on the average only once in ten years. Besides the charms of its climate Mentone offers those of an almost tropical vegetation. Lemon-trees, olive-trees and pines rise in successive stages on surrounding slopes. The district produces 40,000,000 lemons yearly, and this is its principal natural wealth. In the east bay is the harbour, constructed in 1890. It has a depth of about 26 ft, and is sheltered by a jetty about 400 yds. in length. The harbour is frequented by pleasure yachts and a few coasting vessels.

Mentone was probably the Lumone of the Itineraries, but no Roman remains exist. After having belonged to the counts of Ventimiglia and a noble Genoese family, it was purchased about the 13th century by the Counts of Monaco. During the First Republic and the First Empire it belonged to France, but in 1815 it reverted to the prince of Monaco, who subjected it to such exactions that in 1846 its inhabitants proclaimed the town a commune of the principality, under the protection of Sardinia. In 1860 both Mentone and Roquebrune were purchased by France from the prince of Monaco, and added to the department of the Alpes Maritimes then formed out of the county of Nice, ceded the same year to France by Sardinia.

MENTOR, in Greek legend, the son of Alcimus and the faithful friend of Odysseus. During the absence of the latter, Mentor was entrusted with the care of his household and the guardianship of his son Telemachus. The word "mentor" is now used in the sense of a wise and trustworthy adviser, a meaning probably connected with the etymology of the name, from the root mon, -on, seen, in Lat. monere, to advise, monitor, adviser.

The *New English Dictionary* points out that the transferred use is due less to Homer's *Odyssey* than to Fénelon's *Telémache*, in which Mentor is a somewhat prominent character.

MENTOR OF RHODES, brother of Memnon (q.v.), a Greek condottiere who appears first in the service of the rebellious satrap Artabazus of Phrygia in 363. When Artabazus had rebelled a second time and was in 353 forced to flee with Memnon into Macedonia, Mentor entered the service of the Egyptian king Nectanebus, and was sent by him with a body of Greek mercenaries to support the rebellious king Tennes (Tabnit) of Sidon against Artaxerxes III. But Tennes and Mentor betrayed the besieged town to the Persians (344 B.C.). Tennes was killed and Mentor made king of the town of the Persians, but he was due largely to him that Ecbatana was conquered in 343 (Diod. xvi. 45 sqq.). He now closely allied himself with the eunuch Bagos (q.v.), the all-powerful vizier of Artaxerxes III. He was appointed general in Asia Minor, and with the help of Artabazus and Memnon, whose pardon and recall he obtained from the king, subdued the rebels and local dynasts. The most famous among them was Hermias of Atenaros, the protector of Aristotle, who had become master of some towns of Aeolis and Troas. By treachery he made him prisoner and occupied his towns (342 B.C.); Hermias was executed by order of the king (Diod. xvi. 52; Polyaen. vi. 48; pseudo-Arist. Onom. ii. 27; Strabo xiii. 610; Didymus' commentary on Demosthenes Phil. 4, p. 6; cf. Diog. Laërt. vi. 9). Shortly afterwards Mentor died, and was succeeded by his brother Memnon. His son Thymondas commanded in the naval war against Alexander and at the battle of Ipsus (334 B.C., Mem. 633).

MENZEL, ADOLPH FRIEDRICH ERDMANN VON (1815-1903), German artist, was born at Breslau on the 8th of December 1815. His father was at the head of a school for girls, and intended to educate his son as a professor; but he would not thwart his taste for art. Left an orphan in 1832, Menzel had to maintain his family. In 1833 Sachse of Berlin published his first work, an album of pen-and-ink drawings reproduced on stone, to illustrate Goethe's little poem, "Künstlers Erdenwalle," he executed lithographs in the same manner to illustrate *Denkwürdigkeiten aus der brandenburgisch-preussischen Geschichte*, pp. 834-836; "The Five Senses" and "The Prayer," as well as diplomas for various corporations and societies. From 1839 to 1842 he produced 400 drawings, reviving at the same time the technique of engraving on wood, to illustrate the *Geschichte Friedrichs des Großen* ("History of Frederick the Great") by Franz Kugler. He subsequently brought out *Friedrichs des Grossen Armee in ihrer Uniformierung* ("The Uniforms of the Army under Frederick the Great"), *Soldaten Friedrichs des Großen* ("The Soldiers of Frederick the Great"); and finally, by
order of the king Frederick William IV, he illustrated the works of Frederick the Great, Illustrationen zur Geschichte Friedricks des Grossen (1843-1849). By these works Menzel established his claim to be considered one of the first, if not actually the first, of the illustrators of his day in his own line. Meanwhile Menzel had set himself to study unaided the art of painting, and he soon produced a great number and variety of pictures, always showing keen observation and honest workmanship—subjects dealing with the life and achievements of Frederick the Great, and scenes of everyday life, such as “In the Tuileries,” “The Ball Supper,” and “At Confession.” Among the most important of these works are “The Forge” (1875) and “The Market-place at Verona.” Invited to paint “The Coronation of William I. at Koenigsberg,” he produced an exact representation of the ceremony without regard to the traditions of official painting. Menzel died at Berlin on the 9th of February 1905. In Germany he received many honors, and was the first painter to be invested with the order of the Black Eagle.

MENZEL, W. (1798-1873), German poet, critic and literary historian, was born on the 21st of June 1798, at Waldenburg in Silesia, studied at Breslau, Jen and Bonn, and after living for some time in Aarau and Heidelberg finally settled in Stuttgart, where, from 1830 to 1838, he lived in the Württemberg Diet. His first work, a clever and original volume of poems, entitled Streicherse (Heidelberg, 1823), was followed in 1824-1825 by a popular Geschichte der Deutschen in three volumes and in 1829 and 1830 by Rübezahl and Nachissus, the dramatized fairy-stories upon which his reputation as a poet chiefly rests. In 1831 he published the romance of Farore, a lively picture of the period of the Thirty Years’ War; his other writings include Geschichte Europas, 1789-1815 (2 vols. Stuttgart, 1853), and histories of the German War of 1866 and of the Franco-German War of 1870-71. From 1826 to 1848 Menzel edited a “Literaturblatt” in connexion with the Morgenblatt; in the latter year he transferred his allegiance from the Liberal to the Conservative party, and in 1852 his “Literaturblatt” was revived in that interest. In 1866 his political sympathies again changed, and he became the “particularism” of the Prussian “junkers” and the antipathy of south Germany. He died on the 23rd of April 1873 at Stuttgart. His library of 18,000 volumes was afterwards acquired for the library of Strassburg.

MENZELINSK, a town of eastern Poland in the government of Ufa, 142 m. N.W. of the town of Ufa, and 12 m. from the left bank of the Kama. Pop. (1897) 7542. Its fair is one of the most important in the southern Ural region for cattle, hides, furs, grain, tea, manufactured articles, crockery, &c., which are sold to the annual value of £500,000. The town was founded in 1584.

Mephisto,1 in the Faust legend, the name of the evil spirit in return for whose assistance Faust signs away his soul. The origin of the conception and name of Mephistopheles has been the subject of much learned debate. In Dr Faust's Hollenzwang “Mephisto” is one of the seven great princes of hell; “he stands under the planet Jupiter, his regent is named Zadkiel, an enthroned angel of the holy Jehovah . . .; his form is firstly that of a fiery bear, the other and fairer appearance is that of a little man with a black cape and a bald head.” The origin of the idea of Mephisto in Faust’s mind is thus clear. He was once one of the demons of the seven planets, the Maskim of the ancient Akkadian region, a conception transmitted through the Chaldeans, the Babylonians and the Jewish Kabbala to medieval and modern alchemists and magicians. This fact suggests a plausible theory of the origin of the name. In the ancient Mesopotamian religion the Intelligence of Jupiter was Marduk, “the Lord of Light,” whose antithesis was accordingly conceived as the Lord of Darkness. Mephistopheles, then (or rather Mephistophiles, as the Faust-books spell the name) is “who does not love light” (Gr. μή, φῶς, φῶλι).2

1 In the Faustbuch of 1857 it is spelt Mephistophiles; by Marlowe Mephistophiles; by Shakespeare Mephistophelis; by Goethe first appears in the version des Christlich Meinende, c. 1712.
2 Riesewetter, p. 163. To Schröter this derivation seems improbable, and he appears to prefer that from Hebrew Mephez, destroyer.

To Faust himself, somnambulist and medium, Mephistopheles had—according to Kiesewetter—a real existence: he was “the objectification of the transcendental subject of Faust,” an experience familiar in dreams and, more especially, in the visions of mediums and clairvoyants. He was thus a “familiar spirit,” the “daemon” of Socrates; and if he was also half the devil of theology, half the kobold of old German myth, this was only because such objectivations are apt to clothe themselves in forms borrowed from the common stock of ideas current at the time when the seer lives; and Faust lived in an age obsessed with the fear of the devil, and by no means sceptical of the existence of kobolds. It is suggested, then, in the light of the present psychological research, that Mephisto, though (as the Faust-books record) invisible to any one else, was visible enough to Faust himself and to Wagner, the familus who shared his somnambulistic experiences. He was simply Faust’s “other self,” appearing in various guises—as a bear, as a little bane balm, as a monk, as an invisible presence ringing a bell—but always recognizable as the same “familiar.”

The Mephisto of the Faust-books and the puppet plays passed with little or no modification into literature as the Mephistophiles. Mephistopheles has the kobold qualities: he not only was joined to devils and moved about in a sumptuous fare; he indulges in horse-play and is addicted to practical joking of a homely kind. He is, however, also the devil, as the age of reformers required him: a fallen angel who has not forgotten the splendor of his native paradise. He pictures to Faust the glories of heaven, in order to accentuate the horrors of hell to which he triumphantly drags him. Goethe’s Mephisto is therefore another conception. Some of the traditional qualities are indeed preserved: the prison, for instance, in the scene in Auerbach’s Keller shows that he has not altogether shed his character as kobold; and, like the planet-spirits of the old magic he appears alternately in animal and human shape. He is also identified with the personages of old German tradition, he is dressed as a nobleman, a jester, with a little cape of stiff silk, a cock’s feather in his hat, and a long pointed sword; at the witches’ Sabbath on the Brocken he is hailed as “the knight with the horse’s hoof” and Sybel in Auerbach’s Keller is not too drunk not to notice that he limps. But his limp is the only indication that he is Lucifer fallen from heaven. He could not, like Marlowe’s Mephistophiles or Milton’s Satan, regretfully paint the glories of the height from which he has been hurled; for he denies the distinction between high and low, and everything that comes into being deserves to be destroyed.” He is, in short, not the devil of Christian orthodoxy, a spirit conscious of the good against which he is revolted, but akin to the Evil Principle of the older dualistic systems, with their conception of the eternal antagonism between good and evil, light and darkness, creation and destruction. (See Faust.)

MEPPLE, a town in the province of Drente, Holland, 163 m. by rail N. by E. of Zwolle. Pop. (1903) 10,470. It is favourably situated at the confluence of a number of canals and rivers which communicate hence with the Zuider Zee by the Meppeler Diep, and rose rapidly into prominence in the 19th century. The chief business is in butter, eggs, cattle and pigs, while bleaching, dyeing and shipbuilding are also carried on here.

MEQUINEZ (the Spanish form of the Arabic Mihkasa), a city of Morocco, situated 1600 ft. above the sea, about 70 m. from the west coast and 36 m. W.S.W. of Fez, on the road to Rabat, in 33° 56’ N., 4° 26’ W. The town wall with its four-cornered towers is pierced by four gates, one, the Bâ Bardin, with fine tile-work. A lower wall of brick circuit protects the luxuriant gardens in the outskirts. Mequinez at a distance appears a city of palaces, but it possesses few buildings of note except the palace and the mosque of Mulai Ismail, which served as the royal burying-place. The palace, founded in 1634, was described in 1821 by John Windus in his Journey to Mequines (London 1825) as “about 4 m. in circumference, the whole building exceeding massy, and the walls in every part very thick; the outward one about a mile long and 25 ft. thick.” The interior is composed of oblong court-yards surrounded by buildings and arcades. These buildings are more or less square with pyramidal roofs ornamented outside with green glazed tiles, and inside with and tophel, liar (Faust, ed. 1886, i. 25), which is certainly supported by the fact that almost all the names of devils in the magic-books of the 16th century are derived from the Hebrew.

Alles war entlichen war er dazu Grunde get.
richly carved and painted woodwork in Mauresque style. The walls are tiled to a height of 4 or 5 ft, and above they are finished in plaster, whitewashed or carved into filigree work. The population numbers being between thirty and forty thousand. Idriši, writing in a.D. 1100, calls the place Takarart, and describes it as an ordinary citadel, from which the town gradually developed, taking its name from the Mknass Berbers. 

**MERAN**, the chief town of the administrative district of the same name in the Austrian province of the Tirol, 20 m. by rail N.W. of Botzen, on the Brenner line, while the Vintschgau railway connects it with Mals, 37 m. N.W. It is the chief town in the upper Adige valley, a region which bears the special name of the Vintschgau, and is on the high road either to Landeck and the Lower Engadine by the Reschen Scheideck Pass (4002 ft.), or more directly to the Lower Engadine by the Müntner valley and the Ofen Pass (7071 ft.). In 1900 Meran had 9784 inhabitants (or, with the neighbouring villages of Untermais and Obermais, 13,201), mainly German-speaking and Romanist. The town is picturesquely situated, at a height of 1001 ft., at the foot of the vine-clad Küchelberg, and on the right bank of the Passer River, just above its junction with the Adige or Etsch. Meran proper consists mainly of one long narrow street, the Laubengasse, flanked by covered arcades, but the name is often used to include several adjacent villages, Untermais and Obermais being on the left bank of the Passer, while Gratsch is on its right bank and north-west of the main town. The most noteworthy buildings are the parish church (14th to 15th centuries) and the old residence (15th century) of the counts of the Tirol. Meran is best known as a much-frequented resort for consumptive patients, for whom it is well suited by reason of the purity of the air and the comparative immunity of the place from wind and rain in the winter. It is also visited in spring for the aque jur and in autumn for the grape cure.

To the north-west, on the Küchelberg, is the half-ruined castle of Tirol (2006 ft.), the original seat of the family which gave its name to the county. Meran may have been built on the site of an ancient Roman settlement, but is first mentioned in 857. From the 12th century to about 1420 it was the capital of the ever-extending land named after it Tirol, but then had to give way to Innsbruck, while the building of the Brenner railway (1864–1867) and the rise of Botzen has decreased its commercial importance.

(W. A. B. C.)

**MERBECK (or MARBECK), JOHN (d. c. 1585),** English theological writer and musician, was organist of St George's, Windsor, about 1540. Four years later he was convicted of heresy and sentenced to the stake, but received a pardon owing to the intervention of Gardiner, bishop of Winchester, though Gardiner had himself censured Merbeck for compiling an English Concordance of the Bible. This work, the first of its kind in English, was published in 1535 with a dedication to Edward VI. In the same year Merbeck published his annotated *Book of Common Prayer*, intended to provide for musical uniformity in the use of the First Prayer Book of Edward VI., which was several times reprinted in the 16th century. Merbeck wrote several devotional and miscellaneous works of a strongly Calvinist character, and a number of his musical compositions are preserved in manuscript in the British Museum, and at Oxford and Cambridge. He died, probably while still organist at Windsor, about 1585. His son, ROGER MERBECK (1536–1605), a noted classical scholar, was appointed public orator in the university of Oxford in 1564, and in 1565 became a canon of Christ Church and was elected provost of Oriel; he left Oxford on account of an unfortunate marriage, and took to medicine as a profession, becoming the first registrar of the College of Physicians in London, and chief physician to Queen Elizabeth.

**MERCADIER (d. 1500),** French warrior of the 12th century, and chief of freebooters in the service of Richard I. of England. In 1183 he operated for Richard, then duke of Aquitaine, in the Limousin and the Angoumois, taking castles and laying waste the country. We know nothing of him during the ten years 1184–1194, but after Richard's return from Palestine, Mercadier accompanied him everywhere, travelling and fighting by his side. Richard eulogised Mercadier's exploits in his letters, and gave him the estates left by Adémâr de Bânc, who died without heirs about 1190. During the various wars between Richard and Philip Augustus of France, Mercadier fought successively in Berry, Normandy, Flanders and Brittany. When Richard was mortally wounded at the siege of Châtus in March 1199, Mercadier avenged him by hanging the defenders of the château and slaying the crossbowman who had shot the king. Mercadier then entered the service of John, and ravaged Gascony. On Easter Monday, the 10th of April 1200, he was assassinated while on a visit to Bordeaux to pay his respects to Eleanor of Aquitaine, who was bringing from Spain Blanche of Castile. His murderer was an agent of Brandin, another freebooter in the service of John.

**MERCANTILE (or COMMERCIAL) AGENCIES**, the name given in America to organizations designed to collect, record and distribute to regular clients information relative to the standing of commercial firms. In Great Britain and some European countries trade protective societies, composed of merchants and tradesmen, are formed for the promotion of trade, and members exchange information regarding the standing of business houses. These societies had their origin in the associations formed in the middle of the 19th century for the purpose of disseminating information regarding bankruptcies, assignments and bills of sale. The mercantile agency in the United States is a much more comprehensive organization. It came into existence after the financial crisis of 1837. Trade in the United States had become scattered over a wide territory. Communication was slow, and the town merchant was without adequate information as to the standing of many business men seeking credit. Undoubtedly the severity of the collapse of 1837 was due in part to the insufficiency of this information. New York merchants, who had suffered so severely, determined to organize a headquarters where reports regarding the standing of customers could be exchanged. Lewis Tappan (1788–1873), founder of the Journal of Commerce (1828) and a prominent anti-slavery leader, undertook the work, and established in New York, in 1841, the Mercantile Agency, the first organization of its kind. The system has been wonderfully developed and extended since.

**MERCANTILE SYSTEM**, the name given to the economic policy which developed in Europe at the close of the middle ages. The doctrine of the mercantile system, stated in its most extreme form, made wealth and money identical, and regarded it therefore as the great object of a community so to conduct its dealings with other nations as to attract to itself the largest possible share of the precious metals. Each country's interest was to export the utmost possible quantity of its own manufactures and to import as little as possible of those of other countries, receiving the difference of the two values in gold and silver. This difference is called the balance of trade, and the balance is favourable when more money is received than is paid. Governments might promote their prosperity by production of, or high duties on, the importation of foreign wares, bounties on the export of home manufactures, restrictions on the export of the precious metals—for the purpose of securing such a balance.

But this statement of the doctrine, though current in textbooks, does not represent correctly the views of all who belonged to the mercantile school. Many members of that school were much too clear-sighted to entertain the belief that wealth consists exclusively of gold and silver. The mercantilists may be best described, as W. G. F. Roscher remarked, not by any definite economic theorem which they held in common, but by a set of theoretic tendencies, commonly found in combination, though severely prevailing in different degrees in different minds. The underlying principles may be enumerated as follows: (1) the importance of possessing a large amount of the precious metals; (2) an exaltation (a) of foreign trade over domestic, and (b) of the industry which works up materials over that which produces them; (3) the value of a dense population as an element of national strength; and (4) the employment of state action in furthering artificially the attainment of the ends proposed.
The discoveries in the New World had led to a large development of the European currencies. The old feudal economy, founded partly on dealings in kind, had given way before the new "money economy," and the dimensions of the latter were everywhere expanding. Circulation was becoming more rapid, distant communications more frequent, city life and movable property more important. The mercantilists were impressed by the fact that money is wealth *sui generis*, that it is at all times in universal demand, and that it puts into the hands of its possessor the power of acquiring all other commodities. The period, again, was marked by the formation of great states, with powerful governments at their head. These governments required men and money for the maintenance of permanent armies, which, especially for the religious and Italian wars, were kept up on a great scale. Court expenses, too, were more lavish than ever before, and a larger number of civil officials was employed. The royal domains and duchies were insufficient to meet these requirements, and taxation grew with the demands of the monarchies. Statesmen saw that for their own political ends industry must flourish. But manufactures make possible a denser population and a higher total value of exports than agriculture; they open a less limited and more promptly extensible field to enterprise. Hence they became the object of special governmental favour and patronage, whilst agriculture fell comparatively into the background. The growth of manufactures reacted on commerce, to which a new and mighty arena had been opened by the establishment of colonies. These were then viewed simply as estates to be worked for the advantage of the mother countries, and the aim of statesmen was to make the colonial trade a new source of public revenue. Each nation, as a whole, working for its own power, and the greater ones for predominance, they entered into a competitive struggle in the economic no less than in the political field, success in the former being, indeed, by the rulers, regarded as instrumental to pre-eminence in the latter. A national economic interest was created in which the government could itself the representative head. States became a sort of artificial holocaust for the rearing of urban industries. Production was subjected to systematic regulation, with the object of securing the goodness and cheapness of the exported articles, and so maintaining the place of the nation in foreign markets. The industrial control was exercised, in part directly by the state, but largely also through privileged corporations and trading companies. High duties on imports were resorted to, at first perhaps mainly for revenue, but afterwards in the interest of national production. Commercial treaties were a principal object of diplomacy, the end in view being to exclude the competition of other nations in foreign markets, whilst in the home market as little room as possible was given for the introduction of anything but raw materials from abroad. The colonies were prohibited from trading with other European nations than the parent country, to which they supplied either the precious metals or raw produce purchased with home manufactures.

That the efforts of governments for the furtherance of manufactures and commerce under the mercantile system were really effective towards that end is admitted by Adam Smith, and cannot reasonably be doubted, though doctrinaire free-traders have often denied it. Technical skill must have been promoted by their encouragements; whilst new forms of national production were fostered by attracting workmen from other countries, and by lightening the burden of taxation on struggling industries. Communication and transport by land and sea were more rapidly improved; and the social dignity of the industrial professions was enhanced relatively to that of the classes before exclusively dominant.

The foundation of the mercantile system was at the time when it took its rise inspired by the situation of the European nations. Such a policy had been already in degree practised in the 14th and 15th centuries, thus preceding any formal exposition of its speculative basis. At the commencement of the 16th century it began to exercise a widely extended influence. Charles V. adopted it, and his example contributed much to its predominance. Henry VIII. and Elizabeth conformed their measures to it. The leading states soon entered on a universal competition for manufacturing and commercial preponderance. Through almost the whole of the 17th century the prize, so far as commerce was concerned, remained in the possession of Holland, Italy having lost her former ascendancy by the opening of the new maritime routes, and Spain and Germany being depressed by protracted wars and internal dissensions. The admiring envy of Holland felt by English politicians and economists appears in such writers as Raleigh, Mun, Child and Temple. Cromwell, by his Navigation Act, which destroyed the carrying trade of Holland and founded the English empire of the sea, and Colbert, by his whole economic policy, domestic and international, were the chief practical representatives of the mercantile system.

**MERCAPTANS**  
(Thio-alcohols), organic chemical compounds of the type R.SH (R = an alkyl group). The name is derived from *mercurius captans*, in allusion to the fact that these compounds react readily with mercuric oxide to form crystalline mercury derivatives. The mercaptans may be prepared by the action of the alkyl halides on an alcoholic solution of potassium hydrosulphide; by the reduction of the sulpho-chlorides, *e.g.* C₂H₅SOCl (chlorides of sulphonic acids), by heating the salts of esters of sulphuric acid with potassium hydrosulphide, and by heating the alcohols with phosphorus pentasulphide. They are colourless liquids, which are insoluble in water and possess a characteristic offensive smell. On oxidation by nitric acid they yield sulphonic acids. They combine with aldehydes and ketones, with elimination of water and formation of mercaptans and mercapturic acids. (See SULPHURIC ACID.)

**MERCATOR, GERARDUS** [latinized form of GERHARD KREMER] (1512-1594), Flemish mathematician and geographer, was born at Rupelmonde, in Flanders, on the 5th of March 1512. Having studied at Bois-le-Duc and Louvain (where he matriculated on the 29th of August 1530, and became licentiate in October 1532), he met Gemma Frisius, a pupil of Apian of Ingolstadt, who at the request of the emperor Charles V. had settled in Louvain. From Frisius young Kremer derived much of his inclination to cartography and scientific geography. In 1534 he founded his geographical establishment at Louvain; in 1537 he published his earliest known map, now lost (*Terrae sanctae descriptio*). In 1537-1540 he executed his famous survey and map of Flanders (*Exoticismo Flanriac descriptios*), of which a copy exists in the Musée Plantin, Antwerp. At the order of Charles V. Mercator made a complete set of instruments of observation for the emperor's campaigns: when these were destroyed by fire, in 1546, another set was ordered of the same maker. In 1538 appeared Mercator's map of the world in (north and south) hemispheres, which was rediscovered in 1878 in New York; this work shows Ptolemy's influence still dominant over Mercatorian cartography. In 1541 he issued the celebrated terrestrial globe, which he dedicated to Nicolas Perrenot, father of Cardinal Granvelle; this was accompanied by his *Libellus de usu globi*, which is said to have been presented to Charles V. In 1551 a celestial globe followed. Mercator early began to incline towards Protestantism; in 1553 he had retired for a time from Louvain to Antwerp, partly to avoid inquiry into his religious beliefs; in 1544 he was arrested and prosecuted for heresy, but escaped serious consequences (two of the forty-two arrested with him were burned in one brazier, two buried alive). He now turned thought seriously of emigrating; and when in 1552 Cassander, ordered by the duke of Juliers, Cleves and Berg to organize a university at Duisburg, offered Mercator the chair of cosmography the offer was accepted. The organization of the
university was adjourned, and never completed in Mercator's lifetime; but he now became cosmographer to the duke and permanently settled on the German soil to which many of his ancestors and relatives had belonged. Soon after this, however, he paid a visit to Charles V. at Brussels, and presented the emperor with a cosmos, a celestial sphere enclosing a terrestrial, together with an explanatory Declaratio: this work marks an era in the observation of longitude by magnetic declination, perfected by Halley. Charles rewarded the author with the title of imperatorii domesticus (Hofrat) in the epitaph at Duisburg.

In 1554 Mercator published his great map of Europe in six sheets, three or four of which had already been pretty well worked out at Louvain; a copy of this was rediscovered at Breslau in 1889. Herein, though still greatly under Ptolemy's influence, Mercator begins to emancipate himself; thus Ptolemy's 62° for the length of the Mediterranean, reduced to 58° in the globe of 1541, he now cuts down to 53°. On the 28th of October 1556 he observed an eclipse at Duisburg; in 1563 he was invited by the request of Duke Charles, and completed a map of the same (Lotharingiae descriptio); but it is uncertain if this was ever published. In 1564 he engraved William Camden's map of the British Isles; in 1568 he brought out his Chronologia, hoc est temporum demonstratio... ab initio mundi usque ad annum domini 1568, ex eclipseibus et observationibus astronomici. In the same year was published his memorable planisphere for use in navigation, the first map on "Mercator's projection," with the parallels and meridians at right angles (Novo et octua orbis terrae descriptio ad usum nautigationis accommodata). Improvements were introduced in this projection by Edward Wright in 1590; the more general use of it dates from about 1630, and largely came about through Dieppese support. In 1572 Mercator issued a second edition of his map of Europe; in 1588 appeared his Tabulae geographicae ad mentem Ptolemaei restitutae et emendatae; and in 1585 the first part (containing Germany, France and Belgium) of the Atlas, sive cosmographicae meditatio de fabrica mundi, in which he planned to crown his work by uniting in one volume his various detailed maps, so as to form a general description of the globe. In 1585 he adapted his Europe to the Atlas; in 1587, with the help of his son Rumold, he added to the same a worldmap (Orbis terrarum compendiosa descriptio), followed in 1590 by a second series of detailed maps (Italy, Slavonia, Greece and Candia). The rest of the regional and other plans in this undertaking, mostly begun by Gerard, were finished by Rumold; they include Iceland and the Polar regions, the British Isles (dedicated to Queen Elizabeth), the Scandinavian countries (dedicated to Henrik Ranzovius), Switzerland and Livonia, Russia, Lithuania, France, Spain, the Azores, Africa and America (in the last Michael Mercator, in Asia and Africa Gerard Mercator the younger, assisted) The designs are accompanied by cosmographical and other dissertations, some of the theoretical views in which were condemned as heretical (see the Duisburg edition of 1594, folio). In 1592 Mercator published, two years after his first apoplectic stroke, a Harmonia evangeliorum. He died on the 5th of December 1594, and was buried in St Saviour's church, Duisburg. Besides his famous projection, he did excellent service with Ortelius in helping to free the geography of the 16th century from the tyranny of Ptolemy; his map and instrument work is noteworthy for its delicate precision and admirable execution in detail.

(C. R. B.)
mercial success, partly on account of the expense of the caustic soda required, but mainly on account of the great shrinkage (20 to 25%) which took place in the cloth. An important application of the process in calico printing for the production of permanent crimp or "crepon" effects, which was originally devised by Mercer, was revived in 1890-1891 and is still largely practised by calico printers (see TEXTILE PRINTING). Another application, also dependent upon the shrinking action of caustic soda on cotton, was patented in 1884 by Depouilly, and has for its object the production of crimp effects on piece-goods consisting of wool and cotton or silk and cotton. In the manufacture of such goods cotton binding threads are introduced at definite intervals in the warp or weft, or both, and the piece is passed through cold caustic soda, washed, passed through dilute sulphuric acid, and washed again till neutral. The cotton contracts under the influence of the caustic soda, while both wool and silk remain unaffected, and the desired cramped or puckered effect is produced.

By far the most important application of the mercerizing process is that by which a permanent lustre is imparted to cotton goods; this was discovered in 1889 by H. A. Lowe, who took out a patent for his process in that year, this being supplemented by a further patent in 1890. Since Lowe's invention did not receive sufficient encouragement, he allowed his patents to lapse and the process thus became public property. It was not until 1895, when Messrs Thomas & Prevost patented Lowe's invention, that actual interest was aroused in the new product and the process became a practical success. Their patent was subsequently annulled on the ground of having been anticipated.

The production of a permanent lustre on cotton by mercerizing is in principle a very simple process, and may be effected in two ways. Accurate and reproducible results are obtained by treating the piece in a solution of sodium hydroxide and a subsequent treatment in a solution of strong caustic soda, and then washed, while still stretched, in water. After the washing has been continued for a short time the tension relaxes, and it is then found that the cotton has been shrunk, and that it has also been treated with caustic soda in a manner similar to that of a spun silk though not so pronounced. According to the second method, which constitutes but a slight modification of the first, the cotton is immersed in caustic soda of the strength required for mercerizing, and is then taken out, stretched slightly beyond its original length, and then washed until the tension slackens.

Not all classes of cotton are equally suited for being mercerized. Thus, in the case of yarns the most brilliant lustre is always obtained on twofold or multifold yarns spun from long-stapled cotton (Egyptian Sea Island). On the other hand, some kinds of cotton are only slightly improved in appearance by the process, and are consequently seldom mercerized; and the same applies to twofold yarns made from ordinary American cotton. In piece-goods, long-stapled cottons should be mercerized, but it is also possible that the yarn used for weaving should be twofold. In the great majority of cases, the mercerizing of cotton, whether it be in the yarn or in the piece, is done before bleaching, but sometimes it is found advantageous to mercerize after bleaching, or even after bleaching and dyeing. The strength of the caustic soda employed in practice is generally between 55° and 60°. The temperature of the caustic soda has a material influence on its action on the cotton fibre, and very much stronger solutions being required to produce the same effect at elevated temperatures than at the ordinary temperature, while, on the contrary, by lowering the temperature it is possible to obtain a good lustre with considerably weaker liquors.

Commercially mercerized yarn is sold in the Hank or in the warp, and a great number of machines have been patented and constructed for the purpose. The simplest form of machine for hanks consists essentially of two superposed strong steel rollers, on which the hanks are placed and then passed. The bearing of the hanks is the bearing of the rollers, which run in a slotted groove, and is then raised by mechanical means until the hanks are taut. Caustic soda of 60° is now applied, and the upper roller is caused to revolve slowly, the hanks acting as a belt and causing the lower roller to revolve simultaneously. After about three minutes the caustic soda is allowed to drain off and the hanks are washed by spurt pipes until they slacken, when they are taken off and rinsed, first in dilute sulphuric acid and then in pure water. They are finally dried in a calcinatiche in the sun or in the air, or sprayed with water, and then in water till neutral. The hanks are then bleached in the ordinary way and may be subsequently dyed, no diminution being brought about in the lustre by these operations. Cotton yarns are usually passed through a mercerizing machine in continuous motion (see DYEING), but with the guiding rollers and their bearings of stronger construction and the squeezer at each end of the first box with a double nip (three rollers). The first box contains the first solution, the second water, the third dilute sulphuric acid, and the fourth water.

For the continuous mercerizing of cotton in the piece much more complicated and expensive machinery is required than for yarn, since it is necessary to prevent contraction in both length and breadth. The mercerizing range in most use for pieces is a large cylindrical drum in which the fabric is fed and passed in stretching pieces after bleaching, dyeing or printing, and consists essentially of two endless chains carried at either end by sprocket wheels. The chains carry clips which run in slotted grooves in the drum, and move the piece with the drum, which is about 40 ft. in length. The clips close automatically and grip the cloth on either side as it is fed on to the machine from the mangle, in which it has been saturated with caustic soda. The stretching of the piece begins immediately on the cloths entering the mercerizing machine due to the natural tendency of the fabric to diverge by setting the slotted grooves in such a manner that when the piece has travelled about one-third of the length of the machine it is stretched slightly beyond its original width. At this point the effect is increased by a spray of pure water, which is thrown on by means of spurt pipes; and in consequence the tension slackens and the mercerizing is effected. When the piece arrives at the end of the machine the clips open automatically and release it. Thence it passes through the same processes as described above, and then through a second box where washing with water is effected.

In most large works the caustic soda washings, which were formerly run to waste or were partly used up for bleaching, are now used to make up the discharge of other mercerizers to 90°, and the solution is used over again for mercerizing.

Cotton mercerized under tension has not as much affinity for colouring matters as cotton mercerized without tension, and although cotton mercerized by hydraulic treatment retains in the air-dried condition is greater than in the case of ordinary untreated cotton, it is not so great as that held by cotton which has been mercerized without tension. By drying cotton which has been mercerized with or without tension at temperatures above 100° C. its affinity for colouring matters is much decreased.

The cause of the lustre produced by mercerizing has been variously explained, and in some cases antagonistic views have been expressed on the subject. When viewed under the microscope by reflected light, it is usually found that the fibres appear to be elongated and spread out. It is generally assumed that such fibres are caused to exhibit a strong lustre at those points from which the light is reflected from the surface. Cotton mercerized under tension shows a similar appearance. In the yarn or piece the lustre is not due to the stretching, but results from the enlargement of the fibre due to the fact that under tension the tension is distributed over the whole length of the fibre and it is possible to obtain a lustre in all directions. If, however, the cotton has been mercerized under tension, being plastic while still containing the caustic soda, it is stretched and is set in this condition by the washing. Thus the finished product has a large number of the rounder fibres are laid parallel to each other, as in the case of spun silk, and the lustre inherent to the fibre becomes visible to the naked eye.

See The Life and Labours of John Mercer, by E. A. Parnell (Longmans Green & Co.); Die Mercerisation der Baumwolle, by Paul Gardner (Julius Springer, Berlin); Mercerisation, by the editors of The Dyer and Calico Printer (Heywood & Co.).

**MERCHAND** (O. Fr. marchand, modern marchand; from Lat. mercari, to trade, merx, goods, merchandise), a trader, one who buys and sells goods for profit. The term is now usually confined to a wholesale dealer or one who trades on an extended scale with foreign countries.

**MERCIA,** one of the kingdoms of Anglo-Saxon England. The original kingdom seems to have lain in the upper basin of the Trent, comprising the greater part of Derbyshire and Staffordshire, the northern parts of Warwickshire and Leicester-shire, and the southern part of Nottinghamshire. The name (Merc) seems to denote men of the March, and presumably was first applied when this district bordered upon the Welsh. In later times Mercia successively absorbed all the other territories between the Humber and the Thames except East Anglia, and some districts even beyond the Thames.

The origin of the kingdom is obscure. The royal family, according to Felix, Life of St Guthlac (Anglo-Saxon version), were called Ildingas. Icel, their ancestor, may have been the founder of the kingdom, but nothing is known of him. The family, however, claimed descent from the ancient kings of Angle (cf. Offa I. and Wermund). The first Mercian king of whom we have any record was Cærl, who apparently reigned about the beginning of the 7th century, and whose daughter Coenbry married Edwin, king of Deira. During Edwin's time Mercia was still an independent kingdom, but it was now governed throughout by princes of its own royal family. Its first prominent appearance in English history may be dated in the year 633, when the Mercian prince Penda joined the Welsh king Cadwalla in overthrowing Edwin. According to the Saxon Chronicle, Penda began to reign in 626, and fought against the
West Saxons at Cirencester in 638. In the Mercian regnal tables, however, he is assigned a reign of only twenty-one years, which as his death took place in 654 or 655, would give us the date of his accession, presumably on the overthrow of Edwin, or perhaps on that of Ceadwalla. During the reign of Oswald Penda clearly reigned under the suzerainty of that king. In 642, however, Oswald was slain by Penda in a battle at a place called Maserfeld, which has not been identified with certainty. During the early part of Oswyo's reign the Northumbrian kingdom was repeatedly invaded and ravaged by the Mercians, and on one occasion (before 651) Penda besieged and almost captured the Northumbrian royal castle at Bamborough. At the same time he extended his influence in other directions, and expelled from the throne of Wessex Coenwulf, who had divorced his sister. Indeed, at this time nearly all the English kingdoms must have acknowledged his supremacy. The kingdom of Middle Anglia, which appears to have included the counties of Northampton, Rutland, Huntingdon, and parts of Bedfordshire, Cambridgeshire, Leicestershire and Lincolnshire, was formed into a dependent principality under his son Peada. At this time also the territory corresponding to the modern counties of Cheshire, Shropshire and Herefordshire seems to have been occupied. The last of these counties is said some time later to have been under the government of another son of Penda, named Merewal. In 654 or 655 Penda again invaded Northumbria, with a huge army divided into thirty legiones, each under a royal prince, among whom were Æthelhere, king of East Anglia, and several Welsh kings. He was defeated and slain, however, by Oswyo, at a river called the Wilnaed. Mercia then came again under Northumbrian rule. Peada, the eldest son of Penda, was allowed to govern the part south of the Trent, while north Mercia was put in charge of Northumbrian officials. Penda, although he did not prohibit the preaching of Christianity, had remained a heathen to the end of his life. His death was followed by the conversion of his kingdom. Peada had embraced Christianity on his marriage with a daughter of Oswyo, and under him the first Mercian bishopric was founded. Shortly afterwards Peada was murdered; but in 658 the Mercians rose under his younger brother Wulfhere and threw off the Northumbrian supremacy.

Wulfhere seems to have been a vigorous ruler, for he extended the power of Mercia as far as it had reached in the days of his father, and even farther. According to the Chronicle he invaded Wessex as far as Ashdown in Berkshire in the year 661. At the same time he conquered the Isle of Wight, which he gave to Æthelwalh, king of Sussex. Between the years 661 and 663 he was defeated by the Northumbrian king Egfrith and had to give up Lindsey. In 675 he again fought with the West Saxons under Æthelred, and after a decisive battle, and shortly afterwards died. His brother Æthelred, who succeeded him, invaded Kent in the following year, and in 679 fought a battle on the Trent against Egfrith, by which he recovered Lindsey. After this, however, we hear little of Mercian interference with the other kingdoms for some time; and it is clear that during the last 15 years of the 7th century Wessex, Sussex, Essex and Kent were frequently involved in strife, it seems likely that the Mercian king had somewhat lost hold over the south of England. In 704 Æthelred resigned the crown and became a monk, leaving his kingdom to Coenred, the son of Wulfhere. Coenred also abdicated five years later and went to Rome. Ceolred, the son of Æthelred, who succeeded, fought against the West Saxon king Ine in 715. On his death in the following year Æthelbald, a distant relative, came to the throne, and under him Mercian supremacy was fully restored over all the kingdom south of the Humber. He reigned for 41 years, and died in 757. Again in 781 the kingdom was occupied by the Danes for a short time by Beornred. He was expelled the same year by Offa, who soon restored the power of Mercia, which seems to have suffered some diminution during the later years of Æthelred. Offa's policy was apparently the extinction of the depen-dengoms. In his reign the dynasties of Kent, Sussex and Essex seem to have disappeared, or at all events to have lost the kingly title. In 787 he associated his son Egfrith with him in the kingdom, and after his death (796) Egfrith reigned alone for a few months. On the death of Egfrith the throne passed to Coenwulf, a descendant of Pybba, father of Penda. In 821 Coenwulf was succeeded by his brother Ceolwulf, who was deprived of the throne in 823, being succeeded by Beornwulf. In 825 Beornwulf was defeated by Egberht, king of Wessex, and in the same year he was overthrown and slain by the East Angles. The supremacy now passed to Wessex.

In 827 Ludeca, the successor of Beornwulf, was slain in battle with five of his earls. Wiglaf, who succeeded him, was expelled two years later by Egberht, but regained the throne in the following year. He died, probably in 839, and was succeeded by Berhtwulf, who reigned until 852. Under these later kings Mercia seems to have extended from the Humber to the Thames, including London, though East Anglia was independent, and that part of Essex which corresponds to the modern county of Essex had been annexed to Wessex after 825. Berhtwulf was succeeded in 852 by Burgred, who married Æthelwold, daughter of Æthelwulf. His power seems to have been more or less dependent on the West Saxons. In 853, with the assistance of Æthelwulf he reduced North Wales to submission. Again in 868 he called upon the West Saxon king Æthelred for assistance against the Danes under Loðbrók's sons, who at this time invaded Mercia after their overthrow of the Northumbrians at York. No battle took place, and the Mercians subsequently made peace with the Danes. In 872 the Danes occupied London on their return from invading Wessex, after which a truce was again made. In 873 the Danes encamped at Torksey in Lincolnshire, and although another truce ensued, they advanced in the following year to Repton, and Burgred was driven from the kingdom. He went to Rome, where he remained until his death. In 874 Ceolwulf, a king's thaga or baron, was made king by the Danes, and definitely acknowledged their overlordship. In 877, after the second invasion of Wessex, the Danes seem to have taken the eastern part of Mercia into their own hands. How long Ceolwulf reigned over the western portion is unknown. About the year 884 the most important person in English Mercia was an earl, Æthelred, who accepted the suzerainty of Alfred, and in or before the year 887 married his daughter Æthelflaed. Æthelred and Æthelflaed appear to have had practically real power, though they did not use the royal title. In 886 London, which had been recovered by Alfred from the Danes, was restored to Æthelred. During the invasion of 893–97 English Mercia was again repeatedly ravaged by the Danes; but in the last of these years, by the united efforts of Alfred and Æthelred, they were at length expelled. With this exception, Watling Street, the Ouse and the Lea, continued to be the boundary between Mercia and the Danish kingdom of East Anglia down to the death of Æthelred, between 910 and 912. The government was then carried on by Æthelflaed, who built a number of fortresses, and in conjunction with her brother, King Edward the Elder, succeeded in expelling the Danes from Derby and Leicester by the year 917–18. After her death in the latter year her daughter Ælfwyn was soon deprived of the government by Edward, and Mercia was definitely annexed to Wessex.

From this time onwards its existence as a separate kingdom was at an end, though during the last years of Eadwig's reign the Mercians and Northumbrians set up Eadgar as king. In the last century of the Saxon period the earls of Mercia frequently occupied a semi-royal position. The most important of these were Ælfgar under Eadgar, Edward and Æthelred, Eadric Streona, under the last-mentioned king, and Leofric, under the Danish kings.

**MERCIE, MARIUS JEAN ANTONIN** (1845—), French sculptor and painter, was born in Toulouse on the 30th of October 1845. He entered the École des Beaux Arts, Paris, and studied under Falguère and Jouffroy, and in 1868 gained the Grand Prix
MERCIER, H.—MERCK I 53

de Rome. His first great popular successes were the "David" and "Gloria Victis," which was shown and received the medal of honour of the Salon. The bronze was subsequently placed in the Square Montholon. "The Genius of the Arts" (1872), a relief, is in the Tuileries, in substitution for Barye's "Napoleon III"; a similar work for the tomb of Michelet (1879) is in the cemetery of Père La Chaise; and in the same year Mercié produced the statue of Arago with accompanying reliefs, now erected at Perpignan. In 1882 he repeated his great patriotic success of 1874 with a group "Quand Même!" replicas of which have been set up at Belfort and in the garden of the Tuileries. "Le Souvenir" (1885), a marble statue for the tomb of Mme Charles Ferry, is one of his most beautiful works. "Regret," for the tomb of Cabanel, was produced in 1892, along with "William Tell," now at Lausanne. Mercié also designed the monuments to "la Chevalier" (1895), erected in the Jardin de l'Infante in the Louvre, and "Faidherbe" (1896) at Lille, a statue of "Thiers" set up at St Germain-en-Laye, the monument to "Baudry" at Père-la-Chaise, and that of "Louis-Philippe and Queen Amélie" for their tomb at Dreux. His stone group of "Justice" is at the Hôtel de Ville, Paris. Numerous other statues, portrait busts, and medallions came from the sculptor's hand, which gained him a medal of honour at the Paris Exhibition of 1878 and the grand prize at that of 1889. Among the paintings exhibited by the artist are a "Venus," to which was awarded a medal in 1883, "Leda" (1884), and "Michael-angelo studying Anatomy" (1885)—his most dramatic work in this medium. Mercié was appointed professor of drawing and sculpture at the École des Beaux Arts, and was elected a member of the Académie Française in 1891, after being awarded the biennial prize of the institute of £500 in 1887.

MERCIER, HONORÉ (1849-1894), Canadian lawyer and statesman, was the son of Jean Baptiste Mercier, farmer, and of Marie Kimener, his wife. He was born in the village of St Athanase d'Iberville on the 15th of October 1849. The family came from France, and settled in the district of Montmagny, and later removed to Iberville. Mercier entered the Jesuit College of St Mary, Montreal, at the age of fourteen, and throughout his life retained a warm friendship for the society. He married, firstly in 1866 Leopoldine Boivin, and secondly in 1871 Virginie St Denis. On the completion of his course at St Mary's he studied law in the office of Lafraobise and Papineau, in St Hyacinthe, and was admitted to the bar of the province in April 1865. At the age of twenty-two he became the editor of the Conservative Courrier de St Hyacinthe, and in this journal supported the policy of the Sicotte administration, which then represented the interests of Quebec, under the Act of Union. Mercier was not a member of the Sicotte government, but when Sicotte accepted a seat on the bench, Mercier joined the Opposition, and contributed largely to the defeat of the Ministerial candidate. In 1864 he vigorously opposed the scheme of confederation, on the ground that it would prove fatal to the distinctive position held by the French Canadians. He resumed the editorship of the Courrier in 1866; but after a few months retired from journalism, and for the next five years devoted all his energy to his profession. At the commencement of the year 1871 the national party was organized in Quebec, and Mercier supported the candidates of the party on the platform. In August 1872 he was elected as a member of the House of Commons for the county of Rouville, and proved a vigorous opponent of Sir John A. Macdonald on the question of separate schools for New Brunswick. He was a candidate at the general elections in 1874; but retired on the eve of the contest in favour of another candidate of his own party. Mercier supported the Conservative candidate for the constituency of Malartic in the election of May 1875, and was returned as a Member of Parliament for the county of Malartic. He was elected Speaker of the House in 1876, and was one of the chief contributors to Nicolai's Allgemeine Bibliothek. In 1878 he accompanied the Landgrave Karoline of Hesse-Darmstadt to St Petersburg, and on his return was a guest of the duke Charles Augustus of Weimar in the Wartburg. Unfortunately speculations brought him into pecuniary embarrassment in 1878, and although friends, notably Goethe, were ready to come to his assistance, his losses—combined with the death of five of his children—so preyed upon his mind that he committed
suicide on the 27th of June 1791. Merck distinguished himself mainly as a critic; his keen perception, critical perspicacity and refined taste made him a valuable guide to the young writers of the *Sturm und Drang*. He also wrote a number of small treatises, dealing mostly with literature and art, especially painting, and a few poems, stories, narratives and the like; but they have not much intrinsic importance. Merck's letters are particularly interesting and instructive, and throw much light upon the literary conditions of his time.

**MERCEUR, SEIGNEURS AND DUKES OF.** The estate of Mercœur in Auvergne, France, gave its name to a line of powerful lords, which became extinct in the 14th century, and passed by inheritance to the dauphins of Auvergne, counts of Clermont. In 1426 it passed to the Bourbons by the marriage of Jeanne de Clermont, dauphine of Auvergne, with Louis de Bourbon, count of Montpensier. It formed part of the confiscated estates of the Constable of Bourbon, and was given by Francis I., and Louis de Bourbon, to his son, the Duke of Berri, and his wife, Renée de Bourbon. Nicolas of Lorraine, son of Duke Antoine, was created duke of Mercœur and a peer of France in 1569. His son Philippe Emmanuel (see below) left a daughter, who married the duc de Vendôme in 1600.

**MERCEUR, PHILIPPE EMMANUEL DE LORRAINE, DUC DE (1558–1602), French soldier, was born on the 9th of September 1558, and married Marie de Luxemburg, duchesse de Penthièvre. In 1582 he was made governor of Brittany by Henry III., who had married his sister. Manœur put himself at the head of the League in Brittany, and had himself proclaimed protector of the Roman Catholic Church in the province in 1588. Invoking the hereditary rights of his wife, who was a descendant of the dukes of Brittany, he endeavoured to make himself independent in that province, and organized a government at Nantes, calling his son "prince and duke of Brittany." With the aid of the Spaniards he defeated the duc de Montpensier, whom Henry IV. had sent against him, at Craon in 1592, but the royal troops, reinforced by English contingents, soon recovered. The king being marched against Mercœur in person, and received his submission at Angers on the 20th of March 1598. Mercœur subsequently went to Hungary, where he entered the service of the emperor Rudolph II., and fought against the Turks, taking Stuhlweissenburg (Székcs-Fehérvár) in 1599. Mercœur died on the 10th of February 1602.

**MERCURY** (Mercurius), in Roman mythology, the god of merchandise (mercurialis) and merchants; later identified with the Greek Hermes. His nature is more intelligible and simple than that of any other Roman deity. In the native Italian states no trade existed till the influence of the Greek colonies on the coast introduced Greek customs and terminology. It was no doubt under the rule of the Tarquins that merchants began to ply their trade. Doubtless the merchants practised their religious ceremonies from the first, but their god Mercurius was not officially recognized by the state till the year 495 B.C. Rome frequently suffered from scarcity of grain during the unsettled times that followed the expulsion of the Tarquins. Various religious innovations were made to propitiate the gods; in 496 the Greek warrior, Demeter, Dionysus and Persephone were established in the city, and in 495 the Greek god Mercúrios was introduced into Rome under the Italian name of Mercurius (Livy ii. 21, 27), as protector of the grain trade, especially with Sicily. Preller thinks that at the same time the trade in grain was regulated by law and a regular college or guild of merchants instituted. This college was under the protection of the god; its annual festival was on the 15th (the ides) of May, on which day the temple of the god had been dedicated at the southern end of the Circus Maximus, near the Aventine; and the members were called *mercuriales* as well as *mercatores*. Mommsen, however, considers the *mercuriales* to be a purely local guild—the *pagani* of the Circus valley. The 15th of May was chosen as the feast of Mercury, obviously because Maia was the mother of Hermes, that is of Mercury; and she was worshipped along with her son by the *mercuriales* on this day. According to Preller, this religious foundation had a political object; it established on a legitimate and sure basis the trade between Rome and the Greek colonies of the coast, whereas formerly this trade had been exposed to the capricious interference of government officials. Like all borrowed religions in Rome, it must have retained the rites and the terminology of its Greek original (Festus p. 257). Mercury became the god, not only of the *merculacites* and of the grain trade, but of buying and selling in general; and it appears that, at least in the streets where shops were common, little chapels and images of the god were erected. There was a spring dedicated to Mercury between his temple and the Porta Capena; every shopman drew water from this spring on the 15th of May, and sprinkled it with a laurel twig over his head and over his goods, at the same time entreaty Mercury to remove from his head and his goods the guilt of all his deceits (Ovid, *Fasti*, v. 573 seq.). The word *mercurialis* was popularly used as equivalent to "cheat."

Roman statuettes of bronze, in which Mercury is represented, like his Greek counterpart, standing holding the caduceus and staff in the hand, and wearing the winged cap (the conch, a purely Hellenic representation), are exceedingly common.

**Mercury**, in astronomy, the smallest major planet and the nearest to the sun; its symbol is Υ. Its proximity to the sun makes the telescopic study of its physical constitution extremely difficult. The result is that less is known on this subject than in the case of any other planet. Even the time of rotation on its axis is uncertain. J. H. Schröter inferred a period of rotation of 24 h. 5 m. 30 s., which was in seeming agreement with the observations of K. L. Harding. This period was generally accepted, though Herschel had been unable to see any changes indicating rotation. In 1882 G. Schiaparelli began a careful study of the face of the planet with a refractor of 8 in. aperture, subsequently replaced by one of 18 in. His unexpected conclusion was that the rotation of Mercury resembles that of the moon, in having its period equal to that of its orbital revolution. As the moon always presents the same face to the earth, so Mercury must, in this case, always present very nearly the same face to the sun. Schiaparelli also announced that the axis of the moon is nearly perpendicular to the plane of its orbit. The rotation being uniform, while the orbital motion, owing to the great eccentricity of the orbit, is affected by a very large inequality, it would follow that there is a libration in longitude of nearly 24° on each side of the mean position. Percival Lowell in 1897 took up the question anew by combining a long series of measured diameters of the planet with drawings of its apparent surface. The seeming constancy of the surface appearance was considered to confirm the view of Schiaparelli as to the slow rotation of the planet. But there is wide room for doubt on the question.

The period of orbital revolution of Mercury is nearly 88 days, or somewhat less than three months. Consequently, the period of synodic revolution is less than four months, during which the entire range of phases is completed. When near greatest elongation Mercury shines as a star of the first magnitude, or brighter; but in the latitudes of central and northern Europe it is so near the horizon soon after sunset as to be generally obscured by vapours or clouds. The elongation of the orbit, 0°-20, is far greater than that of any major planet, and nearly the average of that of the minor planets. Consequently, its distance and its greatest elongation from the sun vary widely with its position in its orbit at the time.

The mass of Mercury can be determined only from its action upon Venus; this is so small that the result is doubtful. Leverrier adopted in his tables 1: 30,000,000 as the ratio of the mass of Mercury to that of the sun. S. Newcomb, from the action upon Venus, reduced this to one-half its amount, or 1: 6,000,000.
MERCURY

155

G. W. Hill, basing his conclusions on the probable density of the planet, estimated the mass to be less than 1:10,000,000. The adoption of a mass even as large as that of Newcomb implies a greater density than that of the earth, but it is not possible to estimate the probability that such is the case.

The most interesting phenomenon connected with Mercury is that of its occasional transit over the disk of the sun at inferior conjunction. These occur only when the planet is near one of its nodes at the time. The earth, in its orbital revolution, passes through the line of the nodes of Mercury about the 8th of May and the 10th of November of each year. It is only near one of these times that a transit can occur. The periodic times of Mercury and the earth are such that the transits are generally repeated in a cycle of 46 years, during which 8 transits occur in May and 6 in November. The following table shows the Greenwich mean time of the middle of all the transits from 1677, the date of the first one accurately observed, until the end of the present century.

Transits of Mercury from 1677 to 2003.

A perplexing problem is offered by the secular motion of the perihelion of Mercury. In 1845 Leverrier found that this motion, as derived from observation of the transits, was greater by 35° per century than it should be from the gravitation of all the other planets. This conclusion has been fully confirmed by subsequent investigations, a recent discussion showing the excess of motion to be 43° per century. It follows from this either that the intensity of gravitation does not precisely follow Newton's law.

The most natural explanation was proposed by Leverrier, who attributed the excess of motion to the action of a group of intra-Mercurial planets. At first this conclusion seemed to be confirmed by the fact that occasional observations of the transit of a dark object over the sun had been observed. But no such observation was ever made by an experienced astronomer, and the frequent photographs of the sun, which have been taken at the Greenwich observatory and elsewhere since 1870, have never shown the existence of any such body. We may therefore regard it as certain that, if a group of intra-Mercurial planets exists, its members are too small to be seen when projected on the sun's disk. During the eclipses of 1900 and 1905 the astronomers of the Harvard and Lick Observatories photographed the sky in the neighbourhood of the sun so fully that the stars down to the 7th or 8th magnitude were imprinted on the plates. Careful examination failed to show the existence of any such body. It follows that if the group exists the members must be so small as to be entirely invisible. But in this case they must be so numerous that they should be visible as a diffused illumination on the sky at sunset. Such an illumination is shown by the zodiacal light. But such a group of bodies, if situated in the plane of the ecliptic, would produce a motion of the node of Mercury equal to that of its perihelion, while the observed motion of the node of Mercury is somewhat less than that computed from the gravitation of the known planets. The same is true of the node of Venus, which might also be affected by the same attraction. To produce the observed result, the inclination of the ring would have to be greater than that of the orbit of either Mercury or Venus. In 1853 Newcomb showed that the observed motions, both of the perihelion of Mercury and of the nodes of Mercury and Venus, could be approximately represented by the attraction of a ring of inter-mercurial bodies having a mean inclination of 9° and the mean node in 48° longitude. He also showed that if the ring was placed between the orbits of Mercury and Venus, the inclination would be 7° and the longitude of the node 35°. The fact that the zodiacal light appears to be near the ecliptic, and the belief that, if it were composed of a lens of discrete particles, their nodes would tend to scatter themselves equally around the invariable plane of the solar system, led him to drop these explanations as unsatisfactory, and to prefer provisionally the hypothesis that the sun's gravitation is not exactly as the inverse square. (See Gravitation.)

In 1896 H. H. Seeliger made a more thorough investigation than his predecessor had done of the attraction of the matter producing the zodiacal light, assuming it to be formed of a series of ellipsoids. He showed that the motions of the nodes and perihelion could be satisfactorily represented in this way. The following are the three principal elements of the hypothetical orbits as found by the two investigators:

The demonstration by E. W. Brown that the motion of the moon's perigee is exactly accordant with the Newtonian law of gravitation, seems to preclude the possibility of any deviation from that law, and renders the hypothesis of Seeliger the most probable one in the present state of knowledge. But the question is still an open one whether the zodiacal light has an inclination of the ecliptic as great as that computed by Seeliger. This is a difficult one because the action on Mercury is produced by the inner portions of the matter producing the zodiacal light. These are so near the sun that they cannot be observed, unless possibly during a total eclipse.

(S. N.)

**MERCURY** (symbol Hg, atomic weight = 200), in chemistry, a metallic element which is easily distinguished from all others by its being liquid at even the lowest temperatures naturally occurring in moderate climates. To this exceptional property it owes the synonyms of *quicksilver* in English (with the German *Quecksilber* is the only recognized name) and of *hydrargyrum* (from *hydrargyrum*, water, and *γυρος*, silver) in Graeco-Latin. This metal does not appear to have been known to the ancient Jews, nor it mentioned by the earlier Greek writers. Theophrastus (about 300 B.C.) mentions it as prepared from cinnabar by treatment with copper and vinegar; Dioscorides obtained it from the same mineral with the aid of iron, employing at the same time a primitive distillation apparatus. With the alchemists it was a substance of great consequence. Its appearance commended it as a substance for investigation; many of its compounds, especially corrosive sublimate and calomel, were studied, and improved methods for extracting and purifying the metal were devised. Being ignorant of its susceptibility of freezing into a compact solid, they did not recognize it as a true metal, and yet, on the authority of Geber, they held that mercury (meaning the predominating element in this metal) enters into the composition of all metals, and is the very cause of their metallicity (see Element). When, about the beginning of the 16th century, chemistry and scientific medicine came to merge into one, this same mysterious element of "mercury" played a great part in the theories of pathology; and the metal,
in the free as in certain combined states, came to be looked upon as a powerful medicinal agent.

Occurrence.—Mercury occurs in nature chiefly in the form of a red sulphide, HgS, called cinnabar (q.v.), which, as a rule, is accompanied by more or less of the regeline metal—the latter being probably derived from the former by some secondary reaction. The most important mercury mines in Europe are those of Almadén in Spain and of Idria in Illyria; and in America those of California and Texas. Deposits also occur in Russia, the Bavarian palatinate, in Hungary, Italy, Transylvania, Bohemia, Mexico, Peru and in some other countries.

Mercury occurs in formations of all ages from the Archean to the Quaternary, and it has been found in both sedimentary and eruptive rocks of the most varied character, e.g. conglomerates, sandstones, limestones, limstone-sandstones, quartzite slates, serpentines, crystalline schists, and eruptive rocks from the most acid to the most basic. It appears that nearly all known deposits occur along lines of continuous uplift, where active shearing of the formations has occurred. Large deposits are seldom found in eruptive rocks, but generally near such formations or near active or extinct hot springs. The deposits are of many types, simple fissure veins being less usual than compound, reticulated, or linked veins. Certain deposits are large, impressively so, and the form of the deposit seems to depend chiefly on the physical properties and structure of the enclosing rocks and the nature of the fissure systems that result from their disturbance. The principal ore is cinnabar, a hydrated sulphide of mercury; its occurrence is abundant; the selenide (tiemannite), chlorite, and iodide are rare. Of the associated heavy minerals, pyrite (or marcasite) is almost universal, and chalcoprite, tetrahedrite, blende and realgar are frequently present in smaller quantities. Besides these are the deposits, as the Mergur in Utah, are more valuable for their gold than their mercury content. The usual gangue-forming minerals are quartz, dolomite, calcite, barite, fluor spar and various zeolites. Some fine veins of bituminous matter is one of the most universal and intimate associates of cinnabar. Formerly quicksilver deposits were supposed to be formed by sublimation, but from a careful study of the California occurrences S. B. Christy was convinced as early as 1875 that this was unlikely, and that deposition from hot air was the more probable. By treating the black mercuric sulphide with such solutions, hot and under pressure, he succeeded in producing artificial cinnabar and metacinnabarite. He also showed that the mineral water at the New Almadén mines, when charged with sulphuric acid and heated under pressure, was capable of effecting the same change, and that this method of production agreed better with all the facts than the sublimation theory. (See Genesis of Cinnabar Deposits," Amer. Jour. Sc., xlviii. 1880.) Segger and Becker, "The Quicksilver Deposits of the Pacific" (U.S. Geol. Survey, Mon. xiiii., 1888) established the correctness of these views beyond doubt.

Production.—At one time the world's supply of mercury was almost entirely derived from the Almadén and Idria mines; but now the greater proportion is produced in California and Texas, where cinnabar was used by the Indians as a pigment, and first turned to metallurgical purpose in 1843 by Castellero. In the United States mercury has also been found in Utah, Nevada, Oregon and Arizona. In the 16th century the Almadén and Idria mines were practically the only producers of this metal; statistics of Almadén dating from 1304 and of Idria since 1525 are given in B. Neumann, Die Metalle (1904). Spain produced 1135 metric tons in 1870, and in 1889 its maximum of 1975 tons; since then it has, on the whole, been decreasing. The Austria-Hungary output steadily increased to about 5598 tons at which it appeared to have reached a peak. In the United States production has steadily improved. The United States output was over 1000 tons in 1871, and declined to 800–900 in the period 1899–1902; it has since increased and surpassed the supply from Spain. The following table gives the production in various countries for selected years:

Estimated.

Mercury is transported in steel bottles closed by a screw stopper; the Almaden and Idria bottles contain 76 lb; and until the 1st of June 1904, the Californian bottles contained 765 lb of mercury; they now hold 75 lb. From the smaller works the metal is sometimes sent out in sheepskin bags holding 55 lb of mercury.

Metallurgy.—Chemically speaking, the extraction of mercury from its ores is a simple matter. Metallic mercury is easily volatilized; the ore is powdered and roasted. The resulting vapour, of course, contains much impurity, and is condensed. The residual redness, and cinnabar at a red heat is readily reduced to the metallic state by the action of iron or lime or atmospheric sulphur, the sulphur being eliminated, in the first case as iron sulphide, in the second as sulphur dioxide, and in the third as sulphur oxide. A close iron retort would at first suggest itself as the proper kind of apparatus for carrying out these operations, and this idea was, at one time, acted upon in a few small establishments—for instance, in that of Zweibrücken in the Palatinate, where grain was used as a deposing agent; but the method has now been discarded. In all the large works the decomposition of the cinnabar is effected by the direct exposure of the ore to the oxidizing flame of a furnace, and the mercury vapour, which gets diffused through an immense mass of combustion gases, is recovered in more or less imperfect condensers.

With the exception of the massive deposits of Almadén in Spain and a few of those in California and Idria, cinnabar occurs in forms adapted to the simple, rough process of hand or fireside sorting of the ores is usually practised. Wet concentration has not been successful, because it necessitates ore crushing and extensive slime losses of the brittle cinnabar. As a rule low-grade ores can be handled much more profitably and with less loss and expense. At Almadén in Spain the ores average from 5 to 10%, but in other parts of the world much poorer ores have to be treated. In California, in spite of the high cost of labour, improved furnaces enable ores containing not more than 1% to be worked. The furnaces originally used at Almadén and Idria differ only in the condensing plant. The roasting was carried out in internally fired, vertical shafts of brickwork and at Almadén, the vapours were led through a series of bottles named aludels, so arranged that the neck of one entered the sole of the next; and at Idria the vapours were led into large brickwork chambers lined with cement, and there condensed. The aludel furnace, which was designed in 1633 by Logus and in 1658 by Huygen, was first used at Almadén (discovered in 1566), and introduced at Almadén in 1646 by Bustamente, by whose name it is sometimes known, has now been entirely given up. The Idria furnace was designed in 1787 by von Leithner; it usually produces a considerable portion of the cinnabar and used sidewise by the aludel furnace. The crude mercury is purified by straining through dense linen or chamois leather bags.

The most important improvements in the metallurgy of mercury are associated with the discoveries of an extensive process by which the coarse ores of cinnabar can be worked, and the replacement of the old discontinuous furnaces by those which work continuously. The most successful of these continuous furnaces was a modification of Count Rumford's continuous lime kiln (vide furnaces), designed by F. B. von Neumann and J. B. Randol, the author of many improvements in the metallurgy of mercury. The success of the continuous coarse-ore furnace at Almadén led Randol to attempt the continuous treatment of fine ores with the aludel furnace, and he designed a new furnace on the same lines, which was the result of these experiments solved the problem completely. It contains several vertical shafts in which the descending ore is retarded at will by inclined shelves, which cause it to be expelled gradually from the furnace. The time of treatment is determined by the rapidity with which the roasted ore is withdrawn at the bottom. Several similar furnaces are in use, as the Knox and Osborne, the Livermore and the Corkam-Spires. Coarse-ore furnaces are recovered in molybdenum chambers, usually provided with water-cooled pipes; from these they pass through earthenware pipes, and finally through others of wood and glass. Not all the yield is in liquid mercury; much of it is entangled in the residue which is recovered after much labour.

The conditions for effective condensation are: (1) The furnace gasses should be well oxidized, to avoid the production of an excess of soot. Gas firing is much the most convenient for the use of this ore. (2) The density of permanent gasses passing through the furnace should be reduced to a minimum consistently with complete oxidation. (3) The cross-section of the condensers should be sufficient to reduce the velocity of the escaping gas and the surface for cooling is important for the condensation of mercuric. The latter requirement is best provided for by hanging wooden aprons in the path of the cooled gases. (4) The temperature of the escaping gasses should not exceed 15° to 20° C., but cooling below this point is not necessary, and in any case is very expensive. Cooling by water is quicker, but more expensive than by air. Water sprays, acting directly on the fumes, have not given good results, on account of the difficulty of recovering the fumed quicksilver. An inward draught is absolutely necessary to control the operation of the
furnaces and condensers and to avoid the salivation of the workmen. (6) The condenser should be easily and quickly cleaned during the operation of the furnace. (7) Both furnaces and condensers should have inclined iron plates in their foundations to prevent the infiltration of water. The construction of quicksilver condensers which shall be strong enough to be made thin, be a good conductor of heat, and resistant to abrasion and the alternate action of heat and cold. It should also be noted that the mercury and warm dilute sulphuric acid, and be not too expensive.

Quicksilver is best removed from the "soot," not by pressure, but by the opposite treatment. A machine in use for this purpose at New Almaden, devised by Colonel von Leicht, consists of an iron bowl, perforated at the bottom, in which revolves a vertical shaft carrying a propeller blade which tosses the soot (mixed with wood ashes and a little coal oil) into the air, so that the entangled mercury is frozen solid when it comes in contact with the cold air. The quicksilver is afterwards collected from the soot by distillation. If no more mercury can be extracted mechanically it is returned to the roasting furnace.

The losses of treatment are: (1) Furnace loss, which is easily reduced to nothing; and (2) condenser loss, which can never be zero. The latter consists of mercury lost as vapour and as mist, and its minimum amount is determined not by the richness of the ore but by the volume of escaping gases, their velocity and temperature. The percentage of loss will be higher with a poor than with a rich ore. On a 3% ore the losses need not exceed 0.5 or 0.4% ore content. On a 1% ore they will run from 5 to 10%.

In properly arranged plants under bad management they may easily be doubled or even trebled. The best operators are the ones who亏损 the lowest percentage of quicksilver. In California the best results have been obtained. The commonsenst in collecting the mercury in the tailing is to fall in a very fine stream through a column of a mixture of nitric acid and mercureic nitrate, or of sulphuric acid, or of potassium bichromate and sulphuric acid; the mixture is allowed to settle in the collecting vessel, and the impure mercurous salt is turned into a vertical vessel or a paper filter. The only really exhausting method is distillation in a vacuum out of a glass apparatus. Many forms of apparatus have been devised to effect this. Recent researches have shown, however, that the mercury vapor is not monoatomic, but is entangled in the distillates of other metals. Absolutely pure mercury does not at all adhere to any surface which does not consist of a metal or metal oxide. Hence the least quantity of it, when placed on a sheet of paper, forms a nearly round-off globule, which retains its form on being rolled about, and, when subdivided, breaks into a number of equally perfect globules, which tend to coalesce when sufficiently near to each other. The presence in it of the mixture prevents the tin from coagulating, and the impure mercury may adhere even to glass, and in a glass vessel, instead of the normal convex, form an irregular flat meniscus.

Properties.—Pure mercury is a freely flowing liquid, which does not wet objects placed in it, and has a silvery white colour and perfect metallic lustre; in very thin layers it transmits a bluish-violet light. It freezes at about −39°C. (Mallet gives −38.85°; Hutchins, −39.44°) with contraction, and the formation of a white, very brittle and malleable mass, easily cut with a knife, and exhibiting crystals belonging to the cubic system. When heated the metal expands very uniformly, and vaporizes at about 360°; the volatility is generally increased by the pressure and it is, therefore, desirable to work at the highest and lowest temperature over which it is fluid render it especially valuable as a thermometric fluid (see THERMOMETRY). The vapour is colourless, and its density points to the conclusion that the molecules are monatomic. Its specific gravity at 0° is 13.5950, i.e. it is about half as heavy again as copper volume for volume, a quarter as heavy again as lead, and nearly twice as heavy as zinc; this property is turned to account in the construction of barometers and air-pumps. Its specific heat is about 0.0133 (see CALORIMETRY); its electrical conductivity is involved in the definition of the ohm (see CONDUCTION, ELECTRIC); and its thermal conductivity is about two thirds that of silver.

Pure mercury remains unchanged in dry air, oxygen, nitrous oxide, carbon dioxide, ammonia and some other gases at ordinary temperatures; hence its application for collecting and measuring gases. If no air it slowly becomes coated with a film of mercuric oxide; and when heated for some time in air or oxygen it becomes transformed into the red mercuric oxide, which decomposes into mercury and oxygen when heated to a higher temperature; this reaction is of great historical importance, since it led to the discovery of oxygen at the hands of Priestley and Scheele. The halogen elements and sulphur combine directly with the metal. Mercury is unattacked by dilute sulphuric acid; the strong acid, however, dissolves it on heating with the formation of sulphur dioxide and mercurous or mercuric sulphate according as mercury is in excess or not. Hydrochloric acid has no action. Dilute nitric acid readily attacks it, mercurous nitrate being formed. In the cold with excess of mercury, mercuric nitrate with excess of acid, or with strong acid, in the warm. The metal dissolves in solutions containing chloride or bromine, and consequently in aqua regia.

Mercury readily dissolves many metals to form a class of compounds termed amalgams, which have considerable applications in the arts.

Compounds of Mercury

Mercury forms two well-defined series of salts—the mercurous salts derived from the oxide HgO, and the mercuric salts from the oxide HgO: the existence of these salts can hardly be inseparably connected with a variable valency, i.e. that mercury is monovalent in mercurous, and divalent in mercuric compounds, for according to Baker mercurous chloride or calomel (g.v.) has the formula HgCl2. Mercurous Oxide, HgO, is an unstable dark-brown power formed when caustic potash acts on calomel; it is decomposed by light or heat, and gives off oxygen with the formation of the residue or mercuric oxide, HgO, in two forms: it occurs as a bright-red crystalline powder (also known as "red precipitate," or as mercurius precipitatjs per se) by heating the metal in air, or by calcining the nitrate, or by the action of cold nitric acid on the metal: or it occurs as a mercuric salt with potash; the difference is probably one of subdivision.

The yellow form is the most reactive and is transformed into the red when heated to 400°. If the red oxide is heated it becomes black, regaining its colour on cooling, and on further heating to 600° it decomposes into, mercury and oxygen. It is slightly soluble in water, to which it imparts an alkaline reaction and strongly metallic taste. A peroxide is obtained as a brown solid from mercury and oxygen, which rapidly decomposes, and a peroxide of mercury (HgO2) is obtained by the action of a typical oxidizing agent, and is obtained by precipitating a solution of mercuric nitrate with potassium iodide. It is blackened by exposure to light. Mercarian idole, HgI2, is a yellowish-white powder which is sparingly soluble in cold water, readily in hot, and prepared by the direct union of its components. Mercarian iodide, HgI2, is a yellowish-green powder obtained by heating its components to about 450°, or by triturating them with a little alcohol; it is also obtained by precipitating a solution of mercuric nitrate with potassium iodide.

Mercarnid, HgS, is a yellowish-white powder, sparingly soluble in water, and containing traces of hydrofluoric acid. A strongly alkaline solution of this salt is known as Nessler's reagent, and is specially used for determining traces of ammonia (see below). Mercarnid iodide dissolves in other iodide solutions to form similar compounds; these solutions are characterized by their exceptionally high specific gravity, and hence are employed in density determinations (see DENSITY). It also forms many other double salts. Oxidation with strong nitric acid gives the iodate, Hg(IO3)2. An iodide, HgI2, intermediate between mercurous and mercuric iodides, is obtained as a yellowish-brown precipitate by precipitating mercurous nitrate with a solution of iodine in potassium iodide. Mercanine fluoride, HgF2, and mercar Fluoride, HgF2, are unstable substances obtained from the corresponding oxide and hydrofluoric acid.

Mercarate and Mercarates.—When mercury is added to a cold crystalline salt (in this case the iodide) the metal forms a white crystalline salt soluble in water by dissolving the metal in cold dilute nitric acid; if the metal be in excess a basic salt Hg(NO3)2, 2HgO is obtained. Several other basic salts are known. By adding an excess of a suitable salt to a mercuric salt solution of variable composition, known in pharmacy as mercaritis solubils Hahnemannis, is obtained.

Mercarine Nitrates.—By dissolving mercury oxide in strong nitric acid; the precipitate obtained is washed with water, and a mercuric nitrate is obtained which gives on the addition of strong nitric acid a white precipitate of 2Hg(NO3)2.H2O. Water decomposes it to give basic salts of variable composition. By dissolving the oxide in dilute nitric acid, the resulting salt Hg(NO3)2.H2O, crystallizing in needles, is obtained.

Mercar sulphide, HgS, is an unstable black powder obtained by acting with sulphured hydrogen, diluted with carbon dioxide, over mercuric oxide and heating to 10°. Mercar sulphide, HgS, is one of the most important
mercury compounds; it is the principal ore, occurring in nature as the mineral cinnabar (g.s.), and is extensively used as a pigment, vermilion (q.v.). It is obtained as a black powder by trituration of mercury with sulphur, the compound thus formed being known in pharmacy as mercuric sulphide, or calomel, which is obtained by dissolving mercuric salt with sulphuretted hydrogen. It is only slightly acted upon by nitric acid; it dissolves in aqua regia; chlorine gives a yellow compound, 2HgS, HgCl; and it dissolves in potash and sulphide solutions to form double salts of variable composition.

**Mercuric Sulphate**, HgSO₄, is a white, sparingly soluble, crystalline substance obtained by adding sodium sulphate to a solution of mercuric nitrate, HgNO₃. The precipitate, HgSO₄, is white, soluble, obtained by dissolving mercury in hot strong sulphuric acid; on digestion with water, it decomposes into a basic salt HgSO₄·2H₂O known as turbith or turpeth mineral, and into an acid salt, H₂SO₄. The precipitate, HgSO₄, is obtained as brilliant red, hexagonal crystals by heating mercury with phosphorus iodide to 300° and removing the mercuric iodide simultaneously formed by means of potassium iodide solution. **Mercurous Phosphate**, Hg₂PO₄, and mercurous phosphate, Hg₂(C₂H₃O₂)₂, are obtained by adding sodium phosphate to solutions of mercurous and mercurous nitrates respectively.

**Mercurious Compounds.**—By the action of ammonia and ammonium compounds yield a number of substances many of which have long been used in medicine. By the action of dry ammonia on calomel mercurous-ammonium chloride, NH₄HgCl, is obtained; aqueous ammonia on calomel gives mercurous chloride, Hg₂Cl₂, and a solution of mercurous nitrate, 2HgClNO₃, or mercuric chloride, HgCl₂, is obtained by adding a solution of mercurous chloride to hot solutions of ammonium chloride and ammonia so long as the precipitate first formed redissolves; the substance separates out on cooling. By precipitating a strongly alkaline solution of mercuric chloride by a large excess of potassium iodide it is possible to get a precipitate, mercurous iodide, Hg₂I₂, which is insoluble and can be dried without loss on a tared filter, and it is converted into pure silver by treatment with potassium cyanide and alcohol.

**Sulphurous Mercuric Sulphate** is precipitated when heated in a closed tube with sodium carbonate, yield a grey to black sublimate of metallic mercury, which readily unites to form visible globules. The metal is precipitated from solutions by digestion with bright copper-foil, a consequence of which is that the metal, when rubbed, disappears and when the quicksilvered copper is heated in a sublimation tube.

Solutions of mercuric salts with hydrosulphuric acid give white precipitates of mercurous sulphide, which becomes jet-black on treatment with ammonia. Stannous chloride, in its twofold capacity as a chloride and a reducing agent, precipitates both mercurous and mercuric solutions, at first as calomel, and on addition of an excess of reagent the precipitate becomes grey, then green, and finally black. Sulphuretted hydrogen, when added very gradually to an acid mercuric solution, gives at first an almost white precipitate, which, on addition of more and more reagent, assumes at last a deep black coloration. By means of this method of precipitation a precipitate is obtained as calomel and weighing the precipitate on a tared filter at 100°.

The precipitate may also be estimated by distillation in a closed tube with lime, the metal being collected and weighed, or by precipitating the solution with an excess of stannous chloride. More conveniently is the method of precipitating as sulphide by an excess of sulphuretted hydrogen, and weighing the precipitate on a tared filter; or by means of a Goehck crucible.

**Pharmacology and Therapeutics.**

The use of mercury as a therapeutic agent is of comparatively recent date. To the Greeks and Romans its value was unknown, and the Arabian physicians only used it for skin affections. It was not till the middle of the 16th century that the special properties of mercury were fully appreciated, but since that time the metal has continued to hold a high though fluctuating value as a medicine. At first the metal in a finely divided state or in vapour was used; but very soon its various compounds were found to be endowed with powers even greater than those of the metal itself, and with the discovery of new compounds the number of mercurial medicines has largely increased.

The British Pharmacopoeia contains some twenty-five mercurial preparations, including those of calomel (q.v.). Only the useful preparations will be mentioned here. Free mercury is contained in Hydrargyrum cum Creta, or grey powder, which consists of precipitated mercury. The valuable and widely used preparation varies somewhat with its age, as old specimens contain some mercuric oxide, which makes them more active. The dose is 1-5 gr., and the preparation is usually recommended for children under 30 minims. The addition of this compound to the mercurial bath makes the mixtures more acceptable. Weak ointments are also prepared from the red and yellow forms of mercuric oxide. The perchloride of mercury or corrosive sublimate is therapeutically the most important salt of mercury. The dose is 1-18 gr. It is incompatible with many substances, and should therefore be prescribed alone. It is decomposed by impure water, and distilled water is therefore used in making the Liquor Hydrargyri Perchloridi, in which form it is widely used. The chloride has only been used as a mercurial bath in the fluid ounce and its dose is 30-60 minims.

The perchloride is also compounded with lime-water to form the Lotio Hydrargyri Flava, or yellow wash, which contains two grains of the salt in 30 minims. It has come into wide use of late years. It has the same dose as the perchloride and is largely prescribed in the Liquor Arsenet Hydrargyri Iodidi, or Donovan’s solution, which contains 1% of mercurous iodide and 5% of potassium iodide.

In discussing the pharmacology of mercury and its compounds, it is of the first importance to observe that metallic mercury is inert as such, and that the same may practically be said of mercuric salts. All mercurious compounds will be converted in the body into mercuric salts, to which the action is due. When metallic mercury is triturated or exposed to air it is partly oxidized, the first stage of its transformation to an active compound being thus:—

Metallic mercury can be absorbed by the skin, passing in minute globules through the ducts of the sweat-glands. The mercury contained in "blue ointment" is certainly thus absorbed, actually circulating in the blood in a very different form, as described below. There is no local action on the skin. The mercuric salts, and especially the chloride and iodide, are probably the most powerful of all known antiseptics. One part of the perchloride in 300,000 will prevent the growth of anthrax, and all bacteria—the strings that are partly enveloped in surgery—kills all known bacteria. The action is apparently specific and not to the fact that the chloride of mercury precipitates albumen, including the albuminous bodies of bacteria, for the iodide is still more powerful as a germicide, though it does not coagulate albumen. These salts can be employed for sterilizing metallic instruments, which they tarnish. As these drugs are essentially poisons they must be used with the greatest care in surgical practice, and as they are particularly deleterious to the secretory structures of the kidney they must not be employed as antiseptics in diseases where renal inflammation is already present or probable. They are therefore contra-indicated for application to the throat in scarlet-fever or to the uterus in cancer or uterine disease. The so-called "mercury" which is largely employed in surgery—kills all known bacteria. The action is apparently specific and not to the fact that the chloride of mercury precipitates albumen, including the albuminous bodies of bacteria, for the iodide is still more powerful as a germicide, though it does not coagulate albumen. These salts can be employed for sterilizing metallic instruments, which they tarnish. If these drugs are essentially poisons they must be used with the greatest care in surgical practice, and as they are particularly deleterious to the secretory structures of the kidney they must not be employed as antiseptics in diseases where renal inflammation is already present or probable. They are therefore contra-indicated for application to the throat in scarlet-fever or to the uterus in cancer or uterine disease. The so-called "mercury" which is largely employed in surgery—kills all known bacteria. It is important to observe that the application of these drugs to the skin is not to destroy any compounds present, but to cause their absorption by the lungs even when no such effect is intended to follow their external application. This fact explains the occurrence of chronic mercurial poisoning in certain trades. The treatment of mercury poisoning is, in cases of poisoning from swallowing the dose, a draught of water; in cases of poisoning from inhaling, the inhalation of ammonia; and in cases of poisoning from absorption through the skin, the use of a saline aperient to complete its action.
decomposes the bile-pigment is arrested by the antiseptic power of the drug, so that the excreta are of a very dark colour. The classical experiments of William Rutherford (1839-1899), of Edinburgh, showed that calomel does not increase the amount of bile formed by the liver, and that the amount of sublimate entering the system is equal to the amount of calomel excreted in the urine by a single dose. The value of calomel in hepatic torpor is as an excretory, not a secretory, cholagogue, the gall-bladder being stimulated to expel its stagnant contents. In large doses mercurials seem to have a direct action on the alimentary tract, but the secretion of the stomach is not increased by the mercury administered by the mouth, in whatever form, is excreted as mercuric sulphide. Prior to this decomposition the mercury exists as a complex soluble compound with sodium, chlorine and sulphur as well as with sodium chloride. The compound is soluble in water, but when decomposed, both electrode, mercury and chlorine, and the amount of haemoglobin in the blood. Whilst this is not always the case the small doses, when continued, produce marked anaemia. The excretion of the drug is accomplished by the whole of the secretions of the body, the most striking of the excretions of the blood, which are usually stated, but the excretion of mercury is slow, and it is typically one of the drugs that are cumulative, like arsenic and digitalis.

MERCY is largely used in affections of the alimentary canal, and has an obscure but unquestionable value in cases of heart-disease and arterial degeneration. But its value in syphilis (see Venereal Diseases) far outweighs all its other uses.

Toxicology. Sodium albuminate is used in the preparation of a salve, and is often used as a suppository. The use of this drug is usually made in the case of corrosive sublimate. There is intense gastro-intestinal inflammation, with vomiting, frequent "rice-water" stools and extreme collapse. The treatment, except when the case is seen at once, is aimed at maintaining the body, and is usually begun with sodium albuminate, but when the drug is administered, both electrode, mercury and chlorine, and the amount of haemoglobin in the blood. The symptoms are aggravated until the tongue and mouth ulcerate, the bone necroses, haemorrhages occur in various parts of the body, and the patient dies of anaemia, septic inflammation or exhaustion. The treatment consists, besides stopping the intake of poison and relieving the symptoms, in the administration of potassium iodide in small, often repeated doses.

MERCY (or Mercy), FRANZ, FREIHERR VON, lord of Mandre and Collenburg (d. 1645), German general in the Thirty Years' War, who came of a noble family of Lorraine, was born at Longwy between 1590 and 1598. From 1666 to 1630 he had attained high military rank, and after distinguishing himself at the first battle of Breitenfeld (1631) he commanded a regiment of foot on the Rhine and defended Rhenfeld against the Swedes with the utmost bravery, surrendering only after enduring a five-months' siege. He now became a general officer of cavalry (General-Feldwachtmeister), and in 1635, 1636 and 1637 took part in further campaigns on the Rhine and Doubs. In September 1638 he was made master-general of ordnance in the army of Bavaria, then the second largest army in Germany. In the next campaign he was practically commander-in-chief of the Bavarians, and at times also of an allied army of Imperialists and Bavarians. He was now considered one of the foremost soldiers in Europe, and was made general field marshal in 1643, when he won his great victory over the French marshal Rantzau at Tuttingen (Nov. 24-25), capturing the marshal and seven thousand men. In the following year Mercy opposed the French armies, now under the duke of Enghien (afterwards the great Comte de Lorraine), on the ponts of the Rhine. He forced a hard march and was lost, the desperate battle of Freiburg, but recovered himself and the RC, by inflicting upon Turenne the defeat of Mergentheim (Marienthal). Later in 1645, fighting once more against Enghien and Turenne, Mercy was killed at the battle of Nördlingen (or Allerheim) at the crisis of the engagement, which, even without Mercy's guiding hand, was almost a drawn battle. He died on the 3rd of November, and was put where he fell, and the French erected a memorial, with the inscription Sta victor, heroen calices.

His first grand-nephew CLAUDIUS FLORIMOND, COUNT MERCY DE VILLETES (1666-1734), Imperial field marshal, son of his brother Kaspar, who fell at Freiburg, was born in Lorraine, and entered the Austrian army as a volunteer in 1682. He won his commission at the great battle of Vienna in the following year; and during seven years of campaigning in Hungary rose to the rank of Rittmeister. A wound sustained at this time permanently injured his sight. For five years more, up to 1697, he was employed in the Italian campaigns, then he was called back to Hungary by Prince Eugène and won on the field of Zenta two grades of promotion. He displayed great daring in the first campaigns of the Spanish Succession War in Italy, twice fell into the hands of the enemy in fights at close quarters and for his conduct at the battle of Cremone (Jan. 31, 1702) received the emperor's thanks and the proprietary colonelcy of a newly raised cuirassier regiment. With this he took part in the Rhine campaign of 1703, and the battle of Friedlingen, and his success as an intrepid leader of raids and forays became well known to friend and foe. He was on that account selected early in 1704 to harry the electorate of Bavaria's dominions. He was soon afterwards promoted General-Feldwachtmeister, in which rank he was engaged in the battle of the Schellenberg (July 2, 1704). In the rest of the war he was often distinguished by his fiery courage. He rose to be general of cavalry in the course of these ten years. His resolute leadership was conspicuous at the battle of Peterwardein (1716) and he was soon afterwards made commander of the Banat of Temesvár. At the great battle of Belgrade (1717) he led the second line of left wing cavalry in a brilliant and decisive charge which drove the Turks to their trenches. After the peace he resumed the administration of Lorraine, where, with the Turkish rule needed a humane and capable governor. But before his work was done he was once more called away to a command in the field, this time in southern Italy, where he fought the battle of Francavilla (June 20, 1719), took Messina and besieged Palermo. For eleven years more he administered the Banat, reorganizing the country as a prosperous and civilized community. In 1734 he was made a general field marshal in the army, but on the 29th of June was killed at the battle of Parma while personally leading his troops. He left no children, and his name passed to Count Argenteau, from whom came the family of Mercy-Argenteau (see below).

MERCY (adapted from Fr. merci, Lat. mercus, reward, compassion, pardon, pity or forgiveness. The Latin word was used in the early Christian ages for the reward that is given in heaven to those who have shown kindness without hope of return. The French word, except in such phrases as Dieu merci, is primarily used in the sense of "thanks," and is seen in the old English expression "gramery," or great mercy, great, many thanks, which Johnson took for "grant me mercy." In the medieval Church there were seven "corporal" and seven "spiritual works of mercy" (Opera misericordiae); these were (a) the giving of food to the hungry and drink to the thirsty, the clothing of the naked, the visitation of the sick and of prisoners, the receiving of strangers, and the burial of the dead; (b) the conversion of sinners, teaching of the ignorant, giving of counsel to the doubtful, forgiveness of injuries, patience under wrong, prayer for the living and for the dead. The order of the Sisters of Mercy is a religious sisterhood of the Roman Church. It is founded chiefly in England and Ireland, but there are branches in the United States of America, in South America and in Australia and New Zealand. It was founded in 1827 in Dublin by Miss Catherine McAuley (1857-1841). The object was to perform the "corporal" and "spiritual works of mercy."
Austrian minister at Turin, at St Petersburg, and in 1766 at Paris, where his first work was to strengthen the alliance between France and Austria, which was cemented in 1770 by the marriage of the dauphin, afterwards Louis XVI., with Marie Antoinette, daughter of the empress Maria Theresa. When four years later Louis and Marie Antoinette ascended the throne, Mercy-Argenteau became one of the most powerful personages at the French court. He was in Paris during the turbulent years which heralded the Revolution, and his powerful aid was given first to Loménie de Brienne, and then to Necker. In 1792 he became governor-general of the Belgian provinces, which had just been reduced to obedience by Austria, and here his ability and experience made him a very successful ruler. Although at first in favour of moderate courses, Mercy-Argenteau supported the action of Austria in making war upon his former ally after the outbreak of the Revolution, and in July 1794 he was appointed Austrian ambassador to Great Britain, but he died a few days after his arrival in London.

MERE. 1. (From Lat. merus, pure, unmixed; O. Fr. mier), an adjective primarily indicating something pure and unmixed; thus “mere wine” implied pure and unadulterated wine, as “mere folly” expressed folly pure and simple. Modern usage has, however, given both to the adjective “mere” and the adverb “merely” a depreciatory and disparaging idea, so that expressions like “the mere truth,” a “mere statement of fact,” &c., often convey the impression that they are far from being “mere” in the sense of “entire” or “absolute,” but are, on the contrary, fragmentary and incomplete. The earlier idea of the word is retained in some legal phrases, especially in the phrase “mere words,” which is employed without help or suggestion from the outside. Another legal phrase is “mere right” (Latin jus merum), i.e. right without possession.

2. A word which appears in various forms in several Teutonic and other languages; cf. Dutch and Ger. Meer. From the cognate Lat. mare are derived the Romanic forms, e.g. Fr. mer, Span. mar, &c.; the word appears also in the derivative “marsh” for “marish”; the ultimate origin has been taken to be an Indo-European root, meaning “to die,” i.e. to lie waste; cf. Sansk. maru, desert), an arm of the sea or estuary; also the name given to lakes, pools and shallow stretches of water inland. In the Fen countries a mere signifies a marsh or a district nearly always under water.

3. (Derived from an O. Eng. source, mere, a wall or boundary; cognate with Lat. marus, a wall), a landmark or boundary, also an object indicating the extent of a property without actual enclosing it. A special meaning is that of a road, which forms a dividing line between two places. A “meresman” is an official appointed by parochial authorities to ascertain the exact boundaries of a parish and to report upon the condition of the roads, bridges, waterways, &c., within them. In the mining districts of Derbyshire a mere is a certain measurement of land in which lead-ore is found.

MEREDITH, GEORGE (1828-1909), British novelist and poet, was born at Portsmouth, Hampshire, on the 12th of February 1828; the parish church register records his baptism on the 9th of April. About his early life few details are recorded, but there is a good deal of quasi-autobiography, derived apparently from early associations and possibly antipathies, in some of his own novels, notably Evan Harrington and Harry Richmond, as to which the judicious may speculate. He had, as he used to boast, both Welsh (from his father) and Irish blood (from his mother) in his veins. His father, Augustus Armstrong Meredith, was a naval outfitser at Portsmouth (mentioned as such in Marryat's Peter Simple); and his grandfather, Melchisedek Meredith, clearly suggested the “Old Mel” of Evan Harrington. Melchisedek was 35 when in 1706 he was initiated as a freemason at Portsmouth; and he appears to have been known locally as “the count,” because of a romantic story as to an adventure he once had at Bath; he was churchwarden in 1801 and 1804; and some of the church plate still bears his name.

Meredith's mother died when he was three years old, and he was made a ward in chancery. He was sent to school at Neuwied on the Rhine, and remained in Germany till he was sixteen. During these impressionable years he imbibed a good deal of the German spirit; and German influence, especially through the media of poetry and music, can often be traced in the cast of his thought and sentiment, as well as in some of the intricacies of his literary style. Returning to England he was at first articled to a solicitor in London, but he had little inclination for the law, and soon abandoned it for the more congenial sphere of letters, of which he had become an eager student. At the age of twenty-one he began to contribute poetry to the magazines, and he eked out a livelihood for some years by journalism, and by articles in the Spectator and other London papers, and for the Isaac Journal, for which he wrote leaders; a certain number of his more characteristic fugitive writings are collected in the memorial edition of his works (1910). In London he became one of the leading spirits in the group of young philosophical and positivistic Radicals, among whom were John (afterwards Lord) Morley, Frederic Harrison, Cotter Morison and Admiral Masse. But during the years when he was producing his finest novels he was practically unknown to the public. In 1849 he married Mrs Nicholls, daughter of Thomas Love Peacock, the novelist, a widow, eight years his senior, whose husband had been accidentally drowned a few months after her first marriage (1844), and who had one child, a daughter; but their married life was broken by separation; she died in 1861, and in 1864 Meredith married Miss Vulliamy, by whom he had a son and daughter. His second wife died in 1885. Up to that time there is little to record in the incidents of his life; he had not been "discovered" except by an "honourable minority" of readers and critics. It must suffice to note that during the Austro-Italian War of 1866 he acted as special correspondent for the Morning Post; and though he saw no actual fighting, he enjoyed, particularly at Venice, opportunities for a study of the Italian people which he turned to account in several of his novels. Towards the close of 1867, when his friend John Morley paid a visit to America, Meredith undertook in his absence the editorship of the Fortnightly Review for Messrs Chapman & Hall. They were not only the publishers of his books, but he acted for many years as their literary adviser, in which capacity he left a reputation for being not only eminently wise in his selection of the books to be published, but both critical and encouraging to authors of promise whose work he found himself obliged to reject. Thomas Hardy and George Gissing were among those who expressed their grateful sense of his assistance. He was indeed one of the last of the old school of "publishers' readers." In his early married life he lived in two houses, and later at Copham between Esher and Leatherhead, where soon after his second marriage he settled at Flint Cottage, Mickleham, near Dorking, where he remained for the rest of his life.

Meredith's first appearance in print was in the character of a poet, and his first published poem "Chillian Wallah," may be found in Chamber's Journal for the 7th of July 1849. Two years later he put forth a small volume of Poems (1851), which was at least fortunate in eliciting the praise of two judges whose opinion was of the first importance to a beginner. Tennyson was at once struck by the individual flavour of the verse, and declared of one poem, "Love in the Valley," that he could not get the lines out of his head. Charles Kingsley's eulogy was at once more public and more particular. In Praser's Magazine he subjected the volume to careful consideration, praising it for richness and quaintness of tone that reminded him of Herrick, for completeness and coherence in each separate poem, and for the animating sweetness and health of the general atmosphere. At the same time he censured the laxity of rhythm, the occasional lack of polish, and the tendency to
overload the description with objective details to the confusion of the principal effect. No doubt as a result of Kingsley’s introduction, two poems by Meredith appeared in Fraser’s Magazine shortly afterwards; but with the exception of these, and a sonnet in the Leader, he did not publish anything for the next five years. In the meanwhile he was busy upon his first essay in prose fiction. It was early in 1856 that the Shaving of Shagpat, a work of singular imagination, humour and romance, made its appearance. Modelled upon the stories of the Arabian Nights, it catches with wonderful ardour the magical atmosphere of Orientalism, and in this genre it remains a unique triumph in modern letters. Though unappreciated by the multitude, its genius was at once recognized by such contemporaries as George Eliot and Dante Gabriel Rossetti, the latter of whom was one of Meredith’s intimate friends. For his next story it occurred to Meredith to turn his familiarity with the life and legendary tradition of the Rhinelander into a sort of imitation of the grotesquerie of the German romanticists, and in 1857 he put forth Farina, a Legend of Cologne, which sought to bring the spirit of German romance to English sympathies and sympathetic the spirit of German romance in the same way that Shagpat had handled Oriental fairy-lore. The result was less successful. The plot of Farina lacks fibre, its motive is insufficient, and the diverse elements of humour, serious narrative, and romance scarcely stand in proportion to one another. But the Ordeal of Richard Feverel, which followed in 1859, transferred Meredith at once to a new sphere and to the altitude of his accomplishment. With this novel Meredith deserted the realm of fancy for that of the philosophical and psychological study of human nature, and Richard Feverel was the first, as it is perhaps the favourite, of those wonderful studies of motive and action which placed him among the demigods of English literature. The essential theme of this fine criticism of life is the question of a boy’s education. It depicts the abortive attempt of a proud and opinionated father, hide-bound by theory and precept, to bring up his son to a perfect state of manhood through a “system” which controls all the faculties of the mind. It shows many of the natural and wholesome instincts and impulses of adolescence. The love scenes in Richard Feverel are gloriously natural and full of vitality, and the book throughout marked a revolution in the English treatment of manly passion. Those who have not read this novel in the original form, with the chapters which were afterwards omitted, have lost, however, the key to many passages in the story: In the following year Meredith contributed to Once a Week, and in 1861 published as a book the second of his novels of modern life, Evan Harrington, originally with the subtitle “He Would be a Gentleman”—in allusion to the hero being the son of “Old Mel,” the tailor—which contains a richly humorous—in its unrevised form, splendidly farcical—plot, with some magnificent studies of character. Afterwards revised, a certain amount of the farcical element was cut out, with the result that, considered as comedy, it has weak spots; but the Comtesse de Salard remains a genuine creation of characters, and is already a classic. Among poems of a more personal nature is the small volume entitled Modern Love, and Poems of the English Roadside, with Poems and Ballads. An attack upon the dramatic poem which gives the volume its title appeared in the Spectator, and is memorable for the fact that Meredith’s friend, the poet Swinburne, with one of his characteristic generous impulses, replied (Spectator, June 7, 1862) in a spirit of fervent eulogy. Some of the individual “sonnets” (of sixteen lines) into which Modern Love is divided are certainly worthy of being ranked with the most subtle and most intense poetic work of the 19th century.

Returning to fiction, Meredith next published Emilia in England (1864), afterwards renamed Sandra Belloni. His powerful story Rhoda Fleming (1865) followed soon afterwards. Vittoria, published in the Fortnightly Review in 1866, and in book form in 1869, is a sequel to Emilia in England. Four years later appeared The Adventures of Harry Richmond in the pages of Cornhill (1870–1871). Its successor was Beauchamp’s Career (Fortnightly Review, 1874–1875), the novel which Meredith usually described as his own favourite. Its hero’s character is supposed to have been founded upon that of Admiral Mazzé. Sandra Belloni, Rhoda Fleming, Vittoria and Beauchamp are all masterpieces of his finest period, rich in incident, character and workmanship. “The House on the Beach” and “The Case of General Opie and Lady Camper” (New Quarterly Magazine, 1877) were slight but glittering exercises in comedy; the next important novel was The Egoist (1879), which shows an increase in Meredith’s twistedness of literary style and is admittedly hard to read for those who merely want a “story,” but which for concentrated analysis and the real drama of the human spirit is an astounding production. In an interesting series of lectures which Meredith delivered at the London Institution in 1877 his main thesis was that a man without a sense of comedy is dead to the finer issues of the spirit, and the conception of Sir Willoughby Patterne, the central figure of The Egoist, is an embodiment of this idea in the flesh. The Tragic Comedians (1880), the next of Meredith’s novels, lighter in texture than his others, combines the spirits of comedy and tragedy in the story of the life of Ferdinand Lassalle, the German Socialist. The appearance of Diana of the Crossways (1885), a brilliant book, full of his ripest character-drawing, though here and there tormenting the casual reader by the novelist’s mannerisms of expression, marks an epoch in Meredith’s career, since it was the first of his stories to strike the general public. Its heroine was popularly identified with Sheridan’s granddaughter, Mrs Norton, and the use made in it of the contemporary story of that lady’s communication to The Times of the cabinet secret of Peel’s conversion to Free Trade had the effect of producing explicit evidence of its inaccuracy from Lord Dufferin and others. As a matter of historical fact it was Lord Aberdeen who himself gave Delane the information, but the popular acceptance of the other version of the incident gave a factitious interest to the novel.

Meanwhile further instalments of poems—Poems and Lyrics of the Joy of Earth (1885)—had struck anew the full, rich expanse of natural realism which is Meredith’s chief poetic characteristic. “The Woods of Westermain,” in particular, has a sense of the mysterious communion of man with nature unapproached by any English poets save Wordsworth and Shelley. Ballads and Poems of Tragic Life (1887) and A Reading of Earth (1888) gave further evidence of the wealth of thought and vigour of expression which Meredith brought to the making of verse. To “the general,” no doubt, Meredith’s verse is prohibitive, or nearly so—for, after all, he has written some poems, like “Martin’s Puzzle,” “The Old Charist,” and “Juggling Jerry,” which anybody can read with ease. But his most characteristic style in verse is so concentrated that any one accustomed to “straightforward” writing, and unwilling to read with the mind rather than with the eye, must needs to, his loss, be put off. His readers, of the verse even more than of the prose, must be prepared to meet him on a common intellectual footing. When once that is granted, however, the music and magic of such poems as “Seed-time,” “Hard Weather,” “The Throstle in February,” “The South-Wester,” “The Lark Ascending,” “Love in the Valley,” “Melampus,” “A Faith on Trial,” are very real, amid all their occasional obscurities of diction.

Meredith had now completed his sixtieth year, and with his advancing years the angles of his individuality began to grow sharper, while the difficulties of his style became accentuated. The increase in mannerism was marked in One of Our Conquerors (1891), otherwise a magnificent rendering of a theme full of both tragedy and comedy, and in the poem of “The Empty Purse” (1892). Neither Lord Ormondi and His Aminta (1894) nor The Amazing Marriage (1895) reached the level of the earlier novels, though in the latter he seemed to catch an afterglow of genius. In 1898 appeared his Odes in Contribution to the Song of French History, consisting of one ode (“France, December 1870”) reprinted from Ballads and Poems (1874), and three others previously unpublished; a fine example of his lofty thought, and magnificent—if often difficult—and individual diction. In 1901 another volume of verse, Social Readings.
of Life, appeared. In later years too he contributed occasional poems to newspapers and reviews and similar publications, which were collected after his death (Last Poems, 1910). His comedy, The Sentimentalists, was performed on the 1st of March 1910; his early but unfinished novel, Celt and Saxon, was also posthumously published in that summer.

From the early 'nineties onward Meredith's fame had been firmly established. His own literary contemporaries still living could join hands with the younger generation of enthusiastic admirers in insisting on a greatness of which they themselves had been unable to persuade the public. He was chosen to succeed Tennyson as president of the Authors' Society; on his seventieth birthday (1898) he was presented with a congratulatory address by thirty of the most prominent men of letters of the day; before he died he had been included by the King in the Order of Merit; and in various other ways his position as the chief living English writer had come to be popularly recognized. The critics discussed him; and new editions of his books (both prose and verse), for which there had long been but scanty demand, were called for. One of the results was that Meredith, with very doubtful wisdom, recast some of his earlier novels; and in the sumptuous "authorized edition" of 1897 (published by the firm of Constable, of which his son, William Maxse Meredith, was a member) very large alterations are made in some of them. In fact, a reader who compares the first and last editions either of Richard Feverel or Even Harrington will notice changes little short of revolutionary. Even in the previously current editions of 1878 onwards, published by Chapman & Hall, Richard Feverel had been considerably shortened as compared with the original three-volume edition; but it was now robbed again of some of its best-known passages. It is no doubt competent to an author himself to revise his earlier published work even to the extent to which Meredith in the 1897 edition revised these novels; but certainly it is not necessary to accept his judgment when this involves the excision in old age of some of the most virile passages of books that were written in the full glow and vigour of his prime.

In Constable's memorial edition (1910) of his complete works the excisions were published separately, and are therefore on record for those to consult who care. But the wise will read Richard Feverel and Even Harrington in the original versions.

Meredith's literary quality must always be considered in the light of the Celtic side of his temperament and the peculiarities of his mental equipment. His nature was intuitive rather than rational; his mental processes were abnormally rapid; and the suppression of connecting associations frequently gives his language, as it gave Browning's, but even to a greater extent, the air of an impenetrably nebulous obscurity. This criticism applies mainly to his verse, but is also true of his prose in many places, though there is much exaggeration about the difficulties of his novels. When once, however, his manner has been properly understood, it is seen to be inseparable from his method of intimation, and to add to the narrative of description both vividness of delineation and intensity of realization. The essential respect in which Meredith's method of describing action and emotion in narrative differs from that of convention is that, while the ordinary method is to relate what happens from the point of view of the onlooker, Meredith frequently describes it from the point of emotion of the actor; and his influence in this direction has largely modified the art of fiction. Herein lies the secret of the peculiar brilliancy of his style, derived from his combination of the narrator with the creator, or—in its strict sense—the seer. The reader, by the transference of the interest from the audience to the stage, is transported into the very soul of the character, and made to feel as he feels and act as he acts. Moreover, Meredith's instinct for psychology is so intimate, and his sense of motive and action so true, that the interaction of character and character directly dominates the sequence of events depicted in his imaginary world, and discloses the moral idea or criticism of life, instead of the preconceived "moral" being merely illustrated by the plot. In building up the minds, actions, creeds, and tragedies or comedies of his imaginary personalities amid the selected circumstances, and inspiring them with the identical motives and educational influences of life itself, Meredith spent an elaboration and profundity of thought and an originality and vigour of analysis upon his novels which in explicitness go far beyond what had previously been attempted in fiction, and which give to his works a philosophical value of no ordinary kind. Simplicity can scarcely be expected of his language, for the interplay of ideas is in itself original and complex, and their interpretation is necessarily original and complex too. But when Meredith is at his best he is only involved with the involution of his subject; the aphorisms that decorate his style are simple when the idea they convey is simple, elaborate only in its elaboration. Pregnant, vividly graphic, capable of infinite shades and gradations, his style is a much finer and subtler instrument than at first appears, and must be judged finally by what it conveys to the mind, and not by its superficial sound upon the conventional ear. It owes something to Jean Paul Richter; something, too, to Carlyle, with whose methods of narrative and indebtedness to the apparatus of German metaphysics it has a good deal in common. To the novelist Richardson, too, a careful reader will find that Meredith, both in manner and matter (notably in The Egoist and in Richard Feverel), owes a good deal; in "Mrs Grandison" in Richard Feverel he even recalls "Sir Charles Grandison" by name; and nobody can doubt that Sir Willoughby Paternoe, both in idea and often in expression, was modelled on Richardson's creation. Careful students of the early 19th-century English novel will find curious echoes again in Meredith of Bulwer-Lytton's (Baron Lytton's) literary manner and romantic outlook. But he was, after all, an originator, and at first suffered in estimation on that score; he wrote in his own way, and what is most characteristic in Meredith remains individual. Like all the great masters, he has his own tone of voice, his own fashion of expressing an idea. Feeling, perception, reflection, judgment, have equal shares in determining his architectonic relation to a problem or a situation. He rings changes on the changing emotions of humanity, but every chime rings true. He is a literary artist. He takes great themes, not little ones; the characters in his fiction are personalities, human beings, neither "heroes" nor "sports"; and he does not descend to pander to lubricity or cater for the "reading public." His gallery of portraits of real human women, not dolls, would alone place him among the front rank of English literature. It is beyond our scope here to enter into details concerning the philosophy which represents Meredith's "criticism of life." Broadly speaking, it is a belief in the rightness and wholeness of Nature, when Nature—"Sacred Reality"—is lovingly and faithfully and trustfully sought and known by the pure use of reason. Man must be "obedient to Nature, not her slave." Mystical as this philosophy occasionally becomes, it is yet an inspiring one, clean, austere and practical; and it is always dominated by the categorical imperative of self-knowledge and the striving after honesty of purpose and thought. A strong vein of political Radicalism runs through Meredith's creed. It is, however, a Radicalism allied to that of the French philosophes, rather than to the contemporary developments of British party politics, though in later life he gave his open support to the Liberal party. In spite of his German upbringing, Meredith was always strongly French in his sympathies, and his appreciation of French character at its best and at its worst is finely shown in his Napoleon odes. In the main his politics may be summed up as a striving after liberty for reason and conscience and the constant progress of humanity—

The cry of the conscience of life:
Keep the young generations in hail,
And bequeath them no tumbled house.

The fact that Bulwer-Lytton's son, the 1st Earl of Lytton, Meredith's junior by three years, took the pen-name of "Owen Meredith," led occasionally to some confusion among un instructed contemporaries, and even the suggestion of a family connexion.
It is part of Meredith's philosophy—and this must be remembered in considering his dictum—that verbal expression is itself a test of right thought and action. Hence is derived his passion for verbal analysis. Hence also his impulse towards and vindication of poetry—meaning still “the best words in the best order”; and hence his own dictum, otherwise perhaps hard to undiscerning minds, that Song itself is the test by which truth may be tried. The passage occurs in “The Empty Purse”—a poem which throughout is a close and thoughtful exposition of Meredith's general views on life—

As of thyself: This furious Yea
Of a speech I hump to repeat.
In the cause I would have prevail,
For seed of a nourishing wheat,

Is it accepted of Song?
Does it sound to the mind through the ear,
Right sober, pure sane? has it disciplined feet?
Thou wilt find it a test severe;
Unerring whatever the theme.
Rings it for Reason a melody clear,
We have bidden old Chaos retreat,
We have called on Creation to hear;
All forces that make us are one full stream.

Meredith is generally ranked far less high as a poet than as a novelist. But he can only be understood and appreciated properly by those who realize that not prose (in the ordinary sense) but poetry was to him the highest form of expression, and that only in it could he fully deliver his message, as a writer who aspired to contribute something more to the common stock of ideas than could be embodied dramatically in prose fiction.

On Meredith's 80th birthday in 1908, the homage of the English literary world was again paid in an address of congratulation. But his health, which for many years had been precarious, was now failing. He died at Flint Cottage, Box Hill, Surrey, on the 18th of May 1909. A strong feeling existed that he should be buried in Westminster Abbey, and a petition to that effect, which was approved by the prime minister, Mr Asquith, was signed by a large number of men of letters. But this was not to be. A memorial service was held in the abbey, but Meredith's own remains, after cremation, were interred at Dorking by the grave of his second wife. He had died only a brief span after his old friend Swinburne, his affection for whom had never suffered abatement, and it was felt that if he had lived, English literature would have had a great addition.

Meredith went the writer who had raised the creative art of the novel, as a vehicle of character and constructive philosophy, to its highest point—a point higher indeed than most contemporary readers were prepared for. The estimate of his genius formed by "an honourable minority," who would place him in the highest class of all, by Shakespeare, has yet to be confirmed by the wider suffrage of posterity.

A carefully compiled bibliography by John Lane was included in George Meredith: Some Characteristics, by R. Le Gallienne (1890). This sympathetic essay in criticism was the first substantial publication addressed to that stimulation of a wider appreciation of Meredith which was carried on by several later books, perhaps the best of which is M. Sturge Henderson's George Meredith: Novelist Post, Reader (1912), but such earlier testimonies to Meredith's importance as Justin McCarthy's, in his History of Our Own Times must not be forgotten. See also J. A. Hammerton, George Meredith in Anecdotes and Criticism (1909). (H. C.)

MEREJKOVSKY (or Merezhkovskiy), DMITRI SERGEYEEVICH (1865— ), Russian novelist and critic, was born at St Petersburg in 1865. His trilogy of historical romances, collectively entitled Christ and Antichrist, has been translated into many European languages, and published in many English and French. It comprises Smert Bogon (Eng. trans. "The Death of the Gods," London, 1901), the central figure in which is Julian the Apostle; Voskresenie Bogi ("The Rerunner," London, 1902), which describes the life and times of Leonardo da Vinci; and Antikhrist: Pietr i Aleksiy ("Peter and Alexis," London, 1905), which is based on the tragic story of the relations between Peter the Great and his son. The influence of Sienkiewicz can be traced in many of Merejkovsky's writings, which include critical studies of Pliny the Younger, Calderon, Montaigne, Ibsen, Tolstoy (Tolstoy as Man and Artist, London, 1902), and of Gorki and other Russian writers. Merejkovsky married Zinaida Nikolaevna, known in Russia for her poems, essays and short stories written under the pseudonym of Zinaida Hippius (or Gippius); her collected poems (1889-1903) were published in Moscow in 1904.

MERES, FRANCIS (1565-1647), English divine and author, was born at Kirton in the Holland division of Lincolnshire in 1565. He was educated at Pembroke College, Cambridge, where he graduated B.A. in 1587, and M.A. in 1591. Two years later he was incorporated M.A. of Oxford. His kinsman, John Meres, was high sheriff of Lincolnshire in 1596, and apparently helped him in the early part of his career. In 1602 he became rector of Wing in Rutland, where he had a school. He died on the 29th of January 1647. Meres rendered immense service to the history of Elizabethan literature by the publication of his Palladis Tamia. Wits Treasury (1598). It was one of a series of volumes of short pithy sayings, the first of which was Polieutphilia: Wits Commonwealth (1597), compiled by John Bodenham or by Nicholas Ling, the publisher. The Palladis Tamia contained moral and critical reflections borrowed from various sources, and embraced sections on books, on philosophy, on music and painting, and a famous "Comparative Discourse of our English poets with the Grecian, Latin, and Italian poets." This chapter enumerates the English poets from Chaucer to Meres's own day, and in each case a comparison with some classical author is instituted. The book was issued in 1634 as a school book, and has been partially reprinted in the Ancient Critical Essays (1811-1813) of Joseph Hazlewood, Professor E. Arber's English Garner, and Gregory Smith's Elisabethan Critical Essays (1904). A sermon entitled Gods Aristineticke (1597), and two translations from the Spanish of Luis de Granada entitled Granados Devotion and the Sinners Guide (1598) complete the list of his works.

Merganser, a word due to C. Gesner (Hist. animalium iii. 129) in 1555, and for long used in English as the general name for a group of fish-eating ducks possessing great diving powers, and forming the genus Mergus of Linnaeus, now regarded by ornithologists as a sub-family, Merginae, of the family Anatidae. The mergansers have a long, narrow bill, with a small but evident hook at the tip, and the edges of both mandibles bised by numerous horns denticulations, whence in English the name of "saw-bill" is frequently applied to them. Otherwise their structure does not much depart from the Anatine or Fuliguline type. All the species bear a more or less developed crest or tuft on the head. Three of them, Mergus merganser or castor, M. sibilatrix, and M. albellus, are found over the northern parts of the Old World, and of these the first two also inhabit the United States of America, which has besides a fourth species, M. cucullatus, said to have occasionally visited Britain. M. merganser, commonly known as the goosander, is the largest species, being nearly as big as the smaller gese, and the adult male in breeding attire is a very beautiful bird, conspicuous with his dark glossy-green head, rich salmon-coloured breast, and the upper part of the body and wings black and white. This full plumage is not assumed till the second year, and in the meantime, as well as in the post-nuptial dress, the male much resembles the female, having, like her, a reddish-brown head, the upper parts grey and the lower white. In this condition the bird is often known as the "dun diver." This species breeds abundantly in many parts of Scandinavia, Russia, Siberia and North America, and occasionally in Scotland. M. serrator, commonly called the "shelduck," is the smallest of the family, and is a forest-bird; and, while the fully-dressed male wants the delicate hue of the lower parts, he has a gorget of rufous mottled with black, below which is a patch of white feathers, broadly edged with black. Both these species have the bill and feet of a bright reddish-orange, while the much smaller M. albellus, known as the smew, has these parts of a lead colour, and the breeding plumage of the adult male is white, with quaint crescentic markings of black, and the flanks most beautifully vermiculated.
Mergentheim—Merian

M. cucullatus, the hooded merganser of North America, is in size intermediate between M. albellus and M. serratirostris; the male is easily recognizable by his broad semicircular crest, bearing a fanshaped patch of white, and his elongated subcapulars of white edged with black. The conformation of the trachea in the male of M. merganser, M. serratirostris and M. cucullatus is very like that of the ducks of the genus Clangula, but M. albellus has a less exaggerated development more resembling that of the ordinary Fuligula. From the southern hemisphere two species of Mergus have been described, M. octococaeus or strasserianus, L. P. Vieillot (N. Dict. d'Hist. naturelle, ed. 2, vol. xiv. p. 223; Gal. des oiseaux, tom. ii. p. 209, pl. 283), inhabiting South America, of which but few specimens have been obtained, having some general resemblance to M. serratirostris, but much more darkly coloured, and M. australis, Hombron and Jacqueton (Ann. sc. nat. zoologie, ser. 2, vol. xvi. p. 320; Voy. au Pol Sud, oiseaux, pl. 31, fig. 2), known only by the unique example in the Paris Museum procured by the French Antarctic expedition in the Auckland Islands.

Often associated with the mergansers is the genus Merganetta, the so-called torrent-ducks of South America, of which six species have been described; but they possess spiny tails and have their wings armed with a spur. These with Hymenolemus Malacorhynchos, the blue duck of New Zealand, and Salavodore waigius is Waigiu are placed in the sub-family Mergentinae. (A. N.)

Mergentheim, a town of Germany, in the kingdom of Württemberg, situated in the valley of the Tauber, 7 m. S. from Lauda by rail. Pop. (1002), 4535. It contains an Evangelical and three Roman Catholic churches, a Latin and other schools, and a magnificent castle with a natural history collection and the archives of the Teutonic order. This is now used as barracks. The industries of the town include tanning, the manufacture of agricultural machinery and wine-making. Near the town is medicinal spring of father-in-law of Mergentheim.

Mergentheim (Moriae domus) is mentioned in chronicles as early as 1058, as the residence of the family of the counts of Hohenlohe, who early in the 13th century assigned the greater part of their estates in and around Mergentheim to the Teutonic order. It rapidly increased in fame, and became the most important of the eleven commanderies of that society. On the secularization of the Teutonic Order in Prussia in 1555, Mergentheim became the residence of the grand master, and remained so until the final dissolution of the order in 1809.

See Höring, Das Karlsbad bei Mergentheim (Mergentheim, 1887); and Schmidt, Garnisonsgeschichte der Stadt Mergentheim (Stuttgart, 1895).

Merger (Fr. merger, to sink), in law, the sinking or "drowning" of a lesser estate in a greater, when the two come together in one and the same person without any intervening estate. In order to effect a merger the two estates must vest in the same person at the same time, must be immediately expectant one on the other, and the expectant estate must be larger than the preceding estate. The term is also used for the extinguishment of any right, contract, &c., by absorption in another, e.g. the acceptance of a higher security for a lower, or the extinguishing of a simple contract in a deed.

Merger, a city of Lower Burma, in the Tenasserim division, bounded on the W. by the Bay of Bengal and on the E. by Siam. Area 9789 sq. m. Two principal rivers cross the district from north to south, running almost parallel to each other for a considerable distance, with the Tenasserim river winding between them till it turns south and flows through a narrow rocky gorge in the westernmost range to the sea. The whole district, from the water's edge to the loftiest mountain on the eastern boundary, may be regarded as almost unbroken forest. The timber trees found towards the interior, and on the higher elevations, are of great size and beauty, the most valuable being teak (Teckona grandis), then-gan (Hopea odorata), ka-nyuen (Dipterocarpus laevis), &c. The coast-line of the district, off which lies an archipelago of two hundred and seven islands, is much broken, and for several miles inland is very little raised above sea-level, and is drained by numerous muddy tidal creeks. Southwards of Mergui town it consists chiefly of low mangrove swamps alternating with small fertile rice plains. After passing the mangrove limits, the ground to the east gradually rises till it becomes mountainous, even to the banks of the rivers, and finally culminates in the general natural barrier dividing Burma from Siam. The four principal rivers are the Tenasserim, Le-nya, Pakchan and Falauk, the first three being navigable for a considerable distance. Coal is found on the banks of the Tenasserim and its tributaries, but is still unworked. Gold, copper, iron and manganese are also found in various parts of the district, and there are tin mines at Maluvin, upon which European methods have been tried without much profit, owing to the cost of labour.

From the notices of early travellers it appears that Mergui, when under Siamese rule, before it passed to the Burmese, was a rich and densely peopled country. On its occupation by the British in 1824-1825 it was found to be almost depopulated—the result of border warfare and of the cruelties exercised by the Burmese conquerors. At that time the entire inhabitants numbered only 10,000. It had a population of 88,744 in 1901, showing an increase of 20% in the decade and giving a density of 9 inhabitants to the sq. mile. Mergui carries on a flourishing trade with Rangoon, Bassein and the Straits Settlements. The chief exports consist of rice, rattans, torches, dried fish, areca-nuts, sesame seeds, molluses, sea-slugs, edible birds' nests and tin. The staple imports are piece goods, tobacco, cotton, earthenware, tea and sugar. The climate is remarkably healthy, the heat due to its tropical situation being moderated by land and sea breezes. The rainfall is very heavy and usually exceeds 150 inches.

Mergui town has risen into prominence in recent years as the centre of the pearling trade in the neighbouring archipelago. The pearling grounds were practically unknown in 1850, but in the following decade they produced pearls and mother-of-pearl shell of considerable value. In 1901 the population was 11,987; but the census is taken at a time when many of the fishermen and their families are away in the islands. There is a considerable coasting trade with other Burmese ports and with the Straits Settlements.

Mergui Archipelago, a cluster of islands in the Bay of Bengal, near the southern coast of Lower Burma. They are chiefly noted for their picturesque beauty, some of them rising to 3000 ft. They are only sparsely inhabited by the island race of Selungs.

Merian, Matthew (1593-1650), Swiss engraver, was born in Basel, on the 25th of September 1593. The family came originally from near Delémont, but in his grandfather's time settled in Basel, where in 1553 it obtained the burgerschip of the city. As Matthew early showed signs of artistic tastes, he was placed (1609) under the care of Dietrich Meyer, a painter and engraver of Zurich (1572-1658). He went on to Nancy in 1613, where he already displayed considerable talents as an engraver. After studying in Paris, Stuttgart (1616) and the Low Countries, he came to Frankfurt, where in 1618 he married the eldest daughter of J. T. de Bry, who was a publisher and bookseller as well as an engraver. Merian worked for some time with his father-in-law in Oppenheim, but then returned to Basel, whence he came back (1624) to Frankfurt after Bry's death (1623), in order to take over his business;
MÉRIDA—MERIDIAN

this remained in his family till 1726, when, after a great fire that destroyed most of the books in stock, it came to an end. In 1625 Merian became a burgher of Frankfort, then the great centre of the book trade in Germany, and lived there till his death on the 22nd of June 1650. Among his many works two deserve to be specially mentioned. The first is the long series of works, each entitled Topographia, which contained descriptions of some 30 countries, illustrated by copper plates, largely done by Merian himself, while the accompanying text was due to Martin Zeiller (1589–1661), an Austrian by birth. The first volume was published in 1642 and described Switzerland, with the Grisons and the Valais; it contains the first known view of the glaciers of Grindelwald. “Austria” appeared in 1649, but the volume relating to Upper Saxony and Bohemia (1650) was the last issued by Merian himself. “France” appeared in 1655–1656, while in 1688 the series (extending to 30 parts, in 18 vols.) came to an end with “Italy,” the volume as to Rome having appeared in 1681. The other great enterprise of Merian was the series entitled Theatrum Europaeum, which appeared in 21 parts between 1635 and 1738—it is a historical chronicle of events in Europe from 1617 onwards. In 1625–1630 Merian published a series of illustrations to the Bible, and in 1649 a Dance of Death. But he is best remembered by his views of towns, which throw a massive light upon ancient value. His best pupil, Wenceslaus Hollar (1607–1677), of Prague, settled in London (1635–1643, 1652–1677), and deservedly carried on the Merian tradition. ([W. A. B. C.)

See Life, by H. Eckardt (Basel, 1887).

MÉRIDA, a city of Mexico and capital of the state of Yucatan, 23 m. by r. S. of Progreso, its port on the Gulf of Mexico. Pop. (1900), 43,630, the Maya element being predominant. Mérida is the centre of an isolated railway system, connected with the ports of Progreso and Campeche, and having short lines radiating in all directions to Pete, Valladolid and Izamal. It stands on a broad, partly open plain near the northern border of the peninsula, where the thin loose soil covering a limestone foundation permits the rapid percolation and evaporation of the rainfall, and therefore supports a comparatively scanty vegetation. It is highly favourable to maquey cultivation, however, and Mérida is the centre of the henequén, sisal fibre, industry. There is an imposing 17th-century cathedral facing a square, and together with the government and episcopal palaces. There are also an old university, with schools of law, medicine and pharmacy, an episcopal seminary and other educational institutions. The most interesting building in the city is a Franciscan convent, dating from 1547, which covers an area of 6 acres and is surrounded by a wall 40 ft. high and 8 ft. thick. It once harboured no less than 2000 friars, but has been allowed to fall into complete decay since the expulsion of the order in 1820. The manufactures include straw hats, hammocks, cigars, soap, cotton fabrics, leather goods, artificial stone, and a peculiar distilled beverage called estacion. The exports are henequén, or sisal fibre, hides, sugar, rum, chicle and indigo—all products of the vicinity. Mérida was founded in 1542 by the younger Esteva de Espinosa at the site of the ancient city of Thö6, whose stone pyramids and furnished building material in abundance for the invaders. It became an episcopal see in 1561.

MERIDA (anc. Augusta Emerita, capital of Lusitania), a town of western Spain, in the province of Badajoz, on the right bank of the river Guadiana, 30 m. E. of Badajoz. Pop. (1904), 11,618. Mérida is a important railway junction, for here the Madrid-Badajoz railway meets the lines from Seville, Huelva and Cáceres. No Spanish town is richer in Roman antiquities. Most of these are beyond the limits of modern Mérida, which is greatly inferior in area to the ancient city. Chief among them is the Roman bridge, constructed of granite under Trajan, or, according to some authorities, under Augustus, and restored by the Visigoths in 686 and by Philip III. in 1610. It comprised 51 arches, 17 of which were destroyed during the siege of Badajoz (1812), and measured 2,575 ft. in length. There are a few remnants of Roman temples and of the colossal wall which encircled the city, besides a Roman triumphal arch, commonly called the Arco de Santiago, and a second Roman bridge, by which the road to Salamanca was carried across the small river Albarregas (Alba Regia). The Moorish alcazar or citadel was originally the chief Roman fort. From the Lago de Proserpina, or Charca de la Albuera, a large Roman reservoir, 3 m. north, water was conveyed to Mérida by an aqueduct, of which 37 enormous piers remain standing, with ten arches in three tiers built of brick and granite. The massive Roman theatre is in good preservation; there are also a few vestiges of an amphitheatre and of a circus which measured 485 yds. by 120. Other Roman remains are exhibited in the archaeological museum, and much Roman masonry is incorporated in the 16th century Mudéjar palace of the dukes of La Roca, the palace of the counts of Los Corbos, and the convent of Santa Eulalia, which is said by tradition to mark the spot where St Eulalia was martyred (c. 300).

Augusta Emerita was founded in 25 B.C. As the capital of Lusitania it soon became one of the most splendid cities in Iberia, and was large enough to contain a garrison of 90,000 men. Under the Visigoths it continued to prosper, and was made an archbishopric. Its fortifications included five castles, nine gates and an eight-mile wall, but in 855 it was stormed by the Moors in 713. Its Moorish governors frequently, and sometimes successfully, asserted their independence, but Mérida was never the capital of any large Moorish state. In 1129 its archbishopric was formally transferred to Santiago de Compostela, and in 1228, when Alphonse IX. of Leon expelled the Moors, Mérida was entrusted to the order of Santiago, in whose keeping it soon sank into decadence.

MERIDEN, a city of New Haven county, Connecticut, U.S.A., in the township of Meriden, S.W. of the centre of the state, about 18 m. N.N.E. of New Haven and about the same distance S.W. of Hartford. Pop. of the township, including the city (1900), 38,665; (1910), 32,066; of the city (1900), 24,266, of whom 715 were foreign-born; (1910), 27,265. Meriden is served by the New York, New Haven & Hartford railway and by an electric interurban line. The city is bisected by the Huron River, a small stream, and through the S.W. part of the township flows the Quinnipiac river. A short distance N.W. of the city, in Hubbard Park, an attractive reservation of more than 900 acres, are the Hanging Hills, three elevations (West Mountain, South Mountain and Cat-Hole Mountain) in a broken range of trap ridges, which have resisted the erosion that formed the lowlands of the Connecticut valley; they rise to a height of about 700 ft. above the sea. In their vicinity, near the boundary of Berlin township, is Merimerone, one of the city's four reservoirs. Meriden is the seat of the Connecticut School for Boys (Reformatory). There are also a public library (1890), a state armory, a hospital, the Curtis Home for orphans and aged women, and a tuberculosis sanitarium supported by the city. Meriden is one of the most important manufacturing cities of Connecticut, and in 1905 produced 59.9% of the plated ware manufactured in the state, and much sterling silver. In 1905 the factory product was valued at $13,753,548, an increase of 17.4% over that of 1900. Meriden was originally a part of the township of Wallingford, but a tract in the northern part of this township was designated as Meriden by an Indian deed of 1664. It was made a separate parish under that name in 1728, but did not become a separate township until 1806. The city was charted in 1857.

See G. W. Perkins, Historical Sketches of Meriden (West Meriden, 1840); C. H. S. Davis, History of Wallingford (Meriden, 1870), and G. F. Curtis and C. Bancroft Gillespie, A Century of Meriden (Meriden, 1906).

MERIDIAN, a city and the county-seat of Lauderdale county, Mississippi, U.S.A., about 90 m. E. of Jackson. Pop. (1890), 10,624; (1900), 14,030, of whom 5787 were negroes (1910 census), 23,485. It is served by the Southern, the Alabama Great Southern, the Mobile & Ohio, and the New Orleans & North Eastern and the Alabama & Vicksburg (Queen &
Crescent Route) railways. It is the seat of the East Mississippi Insane Hospital, of the state Masonic Widows and Orphans’ Home and of the Meridian Women’s College (non-sectarian, opened in 1903), the Meridian Male College (opened in 1901), and, for negroes, the Lincoln School (Congregational) and Meridian Academy (Methodist Episcopal). The city is an important market for cotton grown in the surrounding country, and is the principal manufacturing city in the state. Its factory products, chiefly railway supplies and cotton products, increased in value from $1,584,465 in 1900 to $2,367,600 in 1905, or 60.8% in five years. Mineral waters (especially lithia) are bottled in and near the city. The city was laid out in 1834 at a proposed railway crossing, and was chartered as a city in 1860. In February 1864 General William Tecumseh Sherman, with an army of about 20,000, made an expedition from Vicksburg to Meridian, then an important railway centre and depot for Confederate supplies, chiefly for the purpose of making inoperative the Mobile & Ohio and the Jackson & Selma railways; on the 14th of the month his army entered Meridian, and within a week destroyed nearly everything in the city except the private houses, and tore up over 110 m. of track. In the “Meridian riot” of 1871—a prominent episode of reconstruction—when one of several negroes on trial for urging mob violence had shot the presiding judge, the whites, especially a party from Alabama interested in the trial, killed a number of negroes and burned a negro school; on the 2nd of March 1864 a cyclone caused great loss of life and property.

**MERIDIAN** (from the Lat. *meridianus*, pertaining to the south or mid-day), in general a direction toward the south or toward the position of the sun at mid-day. The terrestrial meridian of a place is the great circle drawn on the earth’s surface from either pole through the place. As determined astronomically the celestial meridian is the great circle passing through the celestial pole and the zenith. The terrestrial meridian as practically determined is the circle on the earth’s surface in which the plane of the terrestrial meridian cuts that surface. Owing to local deviations of the plumb-line the meridian thus determined does not strictly coincide with the terrestrial meridian as ordinarily defined, but the deviation, though perceptible in mountainous regions, is so minute that it is generally ignored.

**MÉRIMÉE, PROSPER** (1803–1870), French novelist, archaeologist, essayist, and in all these capacities one of the greatest masters of French style during the 19th century, was born at Pocé on the 28th of September 1803. His grandfather, of Norman abstraction, had been a lawyer and steward to the marchal de Broglie. His father, Jean François Léonor Mérimée (1737–1826), was a painter of repute. Mérimée had English blood in his veins on the mother’s side, and had English proclivities in many ways. He was educated for the bar, but entered the public service instead. A young man at the time of the Romantic movement, he felt its influence strongly, though his peculiar temperament prevented him from joining any of the coteries of the period. Nothing was more prominent among the romantics than the fancy, as Mérimée himself puts it, for “local colour,” the more unfamiliar the better. He exhibited this in an unusual way. In 1835 he published what purported to be the dramatic works of a Spanish lady, Clara Gazul, with a preface stating circumstantially how the supposed translator, one Joseph L’Estrange, had met the gifted poetess at Gibraltar. This was followed by a still more audacious and marvellous imitation, de Poushkin, in 1837 appeared a small book entitled la Guia (the anagram of Gazul), and giving itself out as translated from the Ilyrían of a certain Hyacinthe Maglanovich. This book, which has greater formal merit than Clara Gazul, is said to have taken in Sir John Bowring, a competent Slav scholar, the Russian poet Pouskhiin, and some German authorities, although not only had it no original, but, as Mérimée declares, a few words of Ilyrian and a book or two of travels and topography were the author’s only materials. In the next year appeared a short dramatic romance, La Jacquerie, in which are visible Mérimée’s extraordinary faculty of local and historical colour, his command of language, his grim irony, and a certain predilection for tragic and terrible subjects, which was one of his numerous points of contact with the men of the Renaissance. This in its turn was followed by a still better piece, the *Chronique de Charles IX.* (1829), which stands towards the 16th century much as the *Jacquerie* does towards the middle ages. All these works were to a certain extent second-hand. But they exhibited all the future literary qualities of the author save the two chiefest, his wonderfully severe and almost classical style, and his equally classical solidity and statuesqueness of construction.

He had already obtained a considerable position in the civil service, and after the revolution of July he was chef de cabinet to two different ministers. He was then appointed to the more congenial post of inspector-general of historical monuments. Mérimée was a born archaeologist, combining linguistic faculty of a very unusual kind with accurate scholarship, with remarkable historical appreciation, and with a sincere love for the arts of design and construction, in the former of which he had some practical skill. In his official capacity he published numerous reports, some of which, with other similar pieces, have been republished in his works. He also devoted himself to history proper during the latter years of the July monarchy, and published numerous essays and works of no great length, chiefly on Spanish, Russian and ancient Roman history. He did not, however, neglect novel writing during this period, and some noteworthy short stories and accounts appeared, chiefly in the *Revue de Paris.* The best of all, Colombo, a Coriscian story of extraordinary power, appeared in 1840. He travelled a good deal; and in one of his journeys to Spain, about the middle of Louis Philippe’s reign, he made an acquaintance destined to influence his future life not a little—that of Mme de Montijo, mother of the future empress Eugénie. Mérimée, though in manner and language the most cynical of men, was a devoted friend, and shortly before the accession of Napoleon III. he had occasion to show this. His friend, Libri Carucci dalla Sommaja, was accused of having stolen valuable manuscripts and books from French libraries, and Mérimée took his part so warmly that he was actually sentenced to and underwent fine and imprisonment. He had been elected of the Academy in 1844, and also of the Academy of Inscriptions, of which he was a prominent member. Between 1840 and 1850 he wrote more tales, the chief of which were *Arène Guiliot* and *Corinna* (1847), this last, on a Spanish subject, hardly ranking below *Colombo.*

The empire made a considerable difference in Mérimée’s life. His sympathies were against democracy, and his habitual cynicism and his religious prejudices made legitimism distasteful to him. But the marriage of Napoleon III. with the daughter of Mme de Montijo at once enlisted what was always strongest with Mérimée—the sympathy of personal friendship—on the emperor’s side. He was made a senator, but his most important rôle was that of a constant and valued private friend of both the “master and mistress of the house,” as he calls the emperor and empress in his letters. He was occasionally charged with a kind of irregular diplomacy, and once, in the matter of the emperor’s *Caesar*, he had to give literary assistance to Napoleon. But for the most part he was strictly the *ami de la maison.* At the Tuileries, at Compigne, at Biarritz, he was a constant though not always a very welcome guest, and his influence over the empress was very considerable and was fearlessly exerted, though he used to call himself, in imitation of Scarron, “le boufion de sa maîtresse.” He found, however, time for not a few more tales, of which more will be said presently, and for correspondences, which are not the least of his literary achievements, while they have an extraordinary interest of matter. One of these consists of the letters which have been published as *Lettres à une inconnue*, another of the letters addressed to Sir Anthony Panizzi, librarian of the British Museum. After various conjectures it seems that the *inconnue* just mentioned was a certain Mile Jenny Daquin of Boulogne. The acquaintance extended over many
years; it partook at one time of the character of love, at another of that of simple friendship, and Mérième is exhibited in the letters under the most surprisingly diverse lights, most of them more or less amiable, and all interesting. The correspondence with Panizzi has somewhat less personal interest. But Mérième often visited England, where he had many friends (among whom the late Mr Ellice of Glengarry was the chief), and certain similarities of taste drew him closer to Panizzi personally, while during part of the empire the two served as the channel for a kind of unofficial diplomacy between the emperor and certain English statesmen. These letters are full of shrewd apercus on the state of Europe at different times. Both series, and others since published, abound in gossip, in amusing anecdotes, in sharp literary criticism, while both contain evidences of a cynical and Rabelaisian or Swiftian humour which was very strong in Mérième. This characteristic is said to be so prominent in a correspondence with another friend, who now lies in the library at Avignon, that there is but little chance of its ever being printed. A fourth collection of letters, of much inferior extent and interest, has been printed by Blaze de Bury under the title of *Le Rubes à une autre inconnue* (1873), and others still by d'Haussonville (1888), and in the *Revue des Deux Mondes* (1896). In the latter years of his life Mérième suffered very much from ill-health. It was necessary for him to pass all his winters at Cannes, where his constant companions were two aged English ladies, friends of his mother. The Terrible Year found him completely broken in health and anticipating the worst for France. He lived long enough to see his fears realized, and to express his grief in some last letters, and he died at Cannes on the 23rd of September 1870.

Mérième's character was a peculiar and in some respects an unfortunate one, but by no means unintelligible. Partly by temperament, partly it is said owing to some childish experience, when he discovered that he had been duped and deceived, he turned morbid, and this tendency was not so much owing to the example of Henri Beyle (Stendhal), who was a friend of his family, and of whom he saw much, Mérième appears at a comparatively early age to have imposed upon himself as a duty the maintenance of an attitude of sceptical indifference and sarcastic criticism. Although a man of singularly warm and affectionate feelings, he obtained the credit of being a cold-hearted cynic; and, though both independent and disinterested, he was abused as a hanger-on of the imperial court. Both imputations were wholly undeserved, and indeed were prompted to a great extent by political spite or by the resentment felt by his literary equals on the other side at the cool ridicule with which he met them. But he deserved in some of the bad as well as many of the good senses of the term the name of a man of the Renaissance. He had the warm partisanship and amiability towards friends and the scorpion-like sting for his foes, he had the ardent delight in learning and especially in matters of art and belles lettres, he had the scepticism, the voluptuousness, the curious delight in the contemplation of the horrible, which marked the men of letters of the humanist period. Even his literary work has this Renaissance character. It is tolerably extensive, amounting to some seventeen or eighteen volumes, but its bulk is not great for a life which was not short, and which was occupied, at least nominally, in little else. About a third of it consists of the letters already mentioned. Rather more than another third consists of the official work which has been already alluded to—reports, essays, short historical sketches, the chief of which latter is a history of Pedro the Cruel (1843), and another of the curious pretended known in Russian story as the false Demetrius (1852). Some of the literary essays, such as those on Beyle, on Turgeniev, &c., where a personal element enters, are excellent. Against others and against the largest published sketches—admirable as they are—Taine's criticism that they want life has some force in them, are however, all marked by Mérième's admirable style, by his sound and accurate scholarship, his strong intellectual grasp of whatever he handled, his cool unprejudiced views, his marvellous faculty of designing and proportioning the treatment of his work. In purely archæo-

**MERINO**

167

logical matters his *Description des peintures de Saint-Savin* is very noteworthy. It is, however, in the remaining third of his work, consisting entirely of tales either in narrative or in dramatic form, and especially in the former, that his full power is perceived. He translated a certain number of things (chiefly from the Russian); but his fame does not rest on these, on his already-mentioned youthful supercheries, or on his later semi-dramatic works. There remain about a score of tales, extending in point of composition over exactly forty years and in length from that of *Colombe*, the longest, which fills about one hundred and fifty pages, to that of *l'Enlevement de la redoute* (1820), which fills but little more than half a dozen. They are unquestionably the best things of their kind written during the century, the only newelles that can challenge comparison with them being the very best of Gautier, and one or two of Balzac. The motives are sufficiently different. In *Colombe* and *Mateo Falcone* (1839), the Corsican point of honour is drawn on; in *Carmen* (written apparently after reading Borrow's Spanish books), the gipsy character in *La Venus d'Ile* (1837) and *Lois* (two of the finest of all), certain grisly superstitions, in the former case that known in a milder form as the ring given to Venus, in the latter a variety of the were-wolf fancy. *Arsène Guillard* is a singular satire, full of sarcastic pathos, on popular morality and religion; *la Chambre bleue*, an 18th-century conte, worthy of C. P. J. Crébillon for grace and wit, and superior to him in delicacy; *The Capture of the Redout* just mentioned is a perfect piece of description; *l'Abbé au bain* is again satirical; *la Double méprise* (the authorship of which was objected to Mérième when he was elected of the Academy) is an exercise in analysis strongly impregnated with the spirit of Stendhal, but better written than anything of that writer's. These stories, with his letters, assure Mérième's place in literature at the very head of the French prose writers of the century. He had undertaken an edition of Brontôme for the Bibliothèque Pléiade, but the undertaking he never completed.

Mérième's works have only been gradually published since his death. There is no uniform edition, but almost everything is obtainable in the collections of MM. Charpentier and Calmann Lévy. Most of the sets of letters above referred to from those of the first *inconnue*, where the introducer was Taine, have essayprefaces on Mérième. Maurice Tourneaux's *Prosper Mérième, sa bibliographie* (1876) and *Prosper Mérième, ses portraits* (1879), are useful, while Emile Paguet and many other critics have dealt with him in a scattered manner. The only complete single book on him by far is *M. F. Chambon's Correspondance inédite* (1897) gives little that is substantive, but supplies and corrects a good many gaps or faults in earlier editions. The translations of Mérième into English have been few and numer-

ous. The *Chronique de Charles IX* was translated by G. Saintbury in 1889 with an introduction; and the same writer has also prefixed a much more elaborate essay, containing a review of Mérième's entire work, to an American translation.

**MERINO**, the Spanish name for a breed of sheep, and hence applied to a woolen fabric. The Spanish word is generally taken to be an adaptation to the sheep of the name of an official (merino) who inspected sheep pastures. This word is from the medieval Latin majorinus, a steward, head official of a village, &c., from major, greater.

The merino is a white short-wool sheep, the male having spiral horns, the ewes being generally hornless. It is bred chiefly for its wool, because, though an excellent grazer and very adaptable, it matures slowly and its mutton is not of the best quality. The wool is close and wavy in staple, reaching 4 in. in length, and surpasses that of all other sheep in fineness; it is so abundant that little but the muzzles, which should be of an orange tint, and hoofs, are left uncovered. The best wool is produced on light sandy soils.

**Merino** is a variety of sheep known in Great Britain, the climatic moisture of which does not favour the growth of the finest wools, but it predominates in all regions where sheep are bred for their wool rather than their mutton, as in the western United States, Cape Colony, Australia, New Zealand and Argentina. In Australasia, especially in New Zealand, the merino has been crossed with Lincolns, Leicesters, Shropshires and other breeds, with the result of improving the quality
of the mutton while sacrificing to some extent that of the wool.

The merino sheep appears to have originated in Africa, whence it was brought by the Moors to Spain and thence spread over Europe, especially to Austria-Hungary, Germany and France. The best-known breeds are the Rambouillet, a large merino named after the village near Paris, to which it was imported towards the end of the 18th century, and the Negretti, which stands in closer relationship to the old Spanish stock and has shorter wool but a more wrinkled fleece. Importations to America began about the beginning of the 19th century. The so-called American merino, the Delaine, the Vermont and the Rambouillet, are well-known breeds in the United States.

The term "merino" is widely employed in the textile industries with very varied meanings. Originally it was restricted to denote the wool of the merino sheep reared in Spain, but owing to the superiority of the wools grown on merino sheep and brought from Botany Bay, the name as applied to them was replaced by the term "botany." In the dress-goods and knitting trades the term "merino" still implies an article made from the very best wool. The term "cashmere," however, is frequently confused with it, although cashmere should be made from true cashmere and not, as is often the case, from the finest botany wool. In the hosiery and remanufactured materials trades the term "merino" is applied to fibre-mixtures of cotton and wool in contradistinction to "all wool" goods.

**MERIONETH** (Welsh, Meirionydd), a county of North Wales, bounded N. by Carnarvon and Denbigh, E. by Denbigh and Montgomery, S.E. by Montgomery, S. by the Dovey (Dyfi) estuary, dividing it from Cardigan, and W. by Cardigan Bay. It is nearly triangular, its greatest length from N.E. to S.W. being about 45 m., its greatest breadth about 30 m. The relief is less bold than that of Carnarvon, but the scenery is rich and varied, and the valleys among the hills are clothed with thick forests. The peaks of Cadair Idris (g.p.) include Pen y gader (head of the chair; 2927 ft.), Aran Fawddwy (2970 ft.); Arenig Fawr (2600 ft.); Y Llethr (2475 ft.), and Rhobell Fawr (2313 ft.). Perhaps the finest of the valleys is that of Dyfi (Dovey) Dyssyn, Tal y llyn (forehead of the lake), Maw (Mawddach), and Ffestiniog. The Dyffryn (Dyfi) drains Bala Lake (Llyn Tegid or Pimblemore), which is fed by two brooks rising at the foot of the Berwyn Hills. The Dyffryn leaves the lake at the north-east corner, near Castell Gwnonwy (erected 1202, hardly traceable), flowing slowly to Corwen, after which it is rapid, and receives the tributaries Alwen, Ceirg, Clywedog and Alun. The Dyfi (Dyfi) rising in a little lake near Aran Fawddwy, passes Machynlleth, and expands into an estuary of Cardigan Bay. Rising north of the A. the Mawddach (Maw) runs south-west, being joined by rivulets. Traeth Bach is formed by the Dyffryn streamlet, among others. Other streams are the Moira, Eden, Cain (variously spelled). Besides Bala and Tal y llyn lakes, there are among the hills over fifty more, e.g. Llyn Mwngwy. Among the waterfalls may be mentioned Rhaiadr y gwnonwy (cascade of the glen), near Corwen, Rhaiadr y Berwyn (black), and Pistyll Cain (Cain's waterspout), some 150 ft. high.

A mountain tract of the county, 15 m. from north to south by 10 m. east to west, stretching from the coast northward, of the Carnarvon group of grits, quartzites and slates, comprising the Merionethshire anticlinal. The central portion of this tract is occupied mainly by Harlech Grits and Menwian beds; it is bordered on the north, east and south by the Lingula, Tremadoc and Carboniferous limestone and on the west by gneisses and argillaceous siltstones and slates, most greenstone. The andesitic rock of Rhobell-fawr is one of the greatest igneous masses in the whole area of the Lingula beds. The Lingula beds are quarried and mined for slate at Ffestiniog, and near Corwen, near which has been found. Bordering the Cambrian area are the Ordovician rocks. The Arenig beds are interstratified with and overlaid by accumulations of volcanic ashes, felspathic traps or lava-flows, which form the rugged heights of Cadair Idris, the Arenig, the Arenigs, Manod and Moelwyn; and these are in turn overlaid by the Llandeilo and Bala beds, the latter including the Bala limestone. Lead and copper ores have been worked near Towyn.

Here and there along the eastern boundary Llandovery and Wenlock strata are included. The structure of the Silurian tract is synclinal; in the Berwyn mountains the Ordovician rocks again appear with associated andesitic and felsitic lavas and tuffs. West of Llandegai, near Corwen, is a small patch of Carboniferous limestone. Glacial drift with boulder clay is a prominent feature in the valleys and on the mountain sides. A good deal of blown sand fringes the coast north and south of Harlech. At the Llyn Arenig Bach a deposit of kieselguhr is formed.

The climate varies much with the elevation, from bleak to genial, as at Aberdyfi (Aberdovey). Grain crops cover a small area only, green crops being poor, and fruits practically nil. While the soil is generally thin, there are fertile tracts in the valleys, and there is some reclaimed land. The small, hardy ponies (known as of Llanbedr, Conway Valley are now almost restricted to this county and Montgomeryshire. Manufactures include woollen stockings, &c, at and near Bala, flannel at Dolgelley (Dolgelley), Towyn, and a few other places. Slate is the chief staple. The Cambrian railway skirts the coast from Portmadoc to A. At Barmouth junction a branch crosses to Dolgelley, where it is joined by a branch of the Great Western railway. Bala and Ffestiniog are also united by the Great Western, and Ffestiniog is further joined with Llandudno junction by the London & North Western railway, and with Portmadoc (Minfordy) by the narrow gauge railway, a light line, opened in 1865, running between Portmadoc and Dyffryn. Luggin 7 m. in.

The tourist traffic is the source of livelihood to many of the inhabitants. The coast is almost un navigable, owing to sandbanks, and the only havens are Barmouth and Aberdyfi.

The area of the ancient county is 427,810 acres or 670 sq. m., with a population in 1891 of 49,212 and in 1901 of 49,149. In the 19th century, however, the population nearly doubled. The area of the administrative county is 422,018 acres. Welsh is the tongue par excellence of Merionethshire. The county returns one member to parliament, and has neither parliamentary nor municipal borough. The urban districts are: Bala (pop. 1544), Barmouth (Abermaw, 2214), Dolgelley (Dolgelley, 2437), Ffestiniog (11,435), Mallwyd (883), Towyn (3756). The shire is in the north-west circuit, and assizes are held at Dolgelley. It is partly in the diocese of St Asaph and partly in that of Bangor, and has 37 ecclesiastical parishes and districts, with parts of four others.

**Merioneth—Meristem.**—This is the only Welsh county retaining in English its primitive British name, latinized into Merioneth, a subdivision of Britannia Secunda, in the Ordovices' territory. The poet Churchyard in 1587 described the county as remote and difficult of access in his day, and it was never made the field of battle in Saxon, Danish or Norman times, nor indeed until close on the period of Welsh loss of independence. There are not many remains, Celtic, Roman or medieval. Caer DRAWY, a British fort on the Dee, is near Corwen, where Owen Gwynedd was posted to repel Henry II. and whither Owen Glendower retired before Henry IV. The numerous crickles are chiefly near the coast. The Roman via occasionalis ran through the country from south to north and was joined by a branch of Watling Street at Tomen y mer (perhaps Heriir Mon) on Sarn Helen, not far from Castell Prynor. Tomen y mer (debris of the wall) and Castell Prynor have yielded Roman bricks, tiles, urns and coins. Castell y Bere, an extensive ruin, and one of Wales's largest castles, has not been inhabited since the time of Edward I. Cymmer Abbey (Y Fanner) near Dolgelley, a Cistercian establishment founded about 1200, and dissolved by Henry VIII., is most perfect at the east end, with lancet windows, and against the south wall there are a few Gothic pillars and arches. The architecture varies from Norman to Perpendicular. Towyn y Bala, east of Bala, is supposed to be a Roman encampment. It was afterwards occupied by the Welsh, to check the English lords marchers. Moel Offrwm is near Dolgelley. Among the county families may be mentioned that of Hengwr, since the Hengwr Welsh MSS. are famous in north Wales and among all Celtic scholars.

**Meristem** (Gr. μεριστή, divided or divisible), a botanical term for tissue which has the power of developing new
forms of tissue, such as the cambium from which new wood is developed.

**MERIVALE, CHARLES** (1808-1893), English historian and dean of Ely, the second son of John Herman Merivale and Louisa Heath Drury, daughter of Dr Drury, head master of Harrow, was born on the 8th of March 1808. His father (1779-1844) was an English barrister, and, from 1831, a commission in bankruptcy; he collaborated with Robert Bland (1779-1825) in his *Collections from the Greek Anthology*, and published some excellent translations from Italian and German. Charles Merivale was at Harrow School (1818 to 1824) under Dr Butler. His chief friends were Charles Wordsworth, afterwards bishop of St Andrews, and Richard Chenevix Trench, afterwards archbishop of Dublin. In 1824 he was offered a writership in the Indian civil service, and went for a short time to Haileybury College, where he was distinguished for proficiency in Oriental languages. But he eventually decided against an Indian career, and went up to St John's College, Cambridge, in 1826. Among other distinctions he came out as fourth classic in 1827, and in 1828 he was elected fellow of St John's. He was a member of the Apostles' Club, his fellow-members including Tennyson, A. H. Hallam, Monckton Milnes, W. H. Thompson, Trench and James Speeding. He was fond of athletic exercises, had played for Harrow against Eton in 1824, and in 1829 rowed in the first inter-university boat-race, when Oxford won. Having been ordained in 1833, he undertook college and university work successfully, and in 1839 was appointed select preacher at Whitchall. In 1848 he took the college living of Lawford, near Manningtree, in Essex; he married, in 1850, Judith Mary Sophia, youngest daughter of George Freere. In 1863 he was appointed chaplain to the Speaker of the House of Commons, declined the professorship of modern history at Cambridge in 1869, but in the same year accepted from Mr Gladstone the deanery of Ely, and until his death on the 27th of December 1893 devoted himself to the spiritual interests of the cathedral. He received many honorary academic distinctions. His principal work was *A History of the Romans under the Empire*, in seven volumes, which came out between 1850 and 1862; but he wrote several smaller historical works, and published sermons, lectures and Latin verses. Merivale as a historian cannot be compared with Gibbon for virility, but he takes an eminently common-sense and appreciative view. The chief defect of his work, inevitable at the time it was composed, is that, drawing the materials from contemporary memoirs rather than from inscriptions, he relies on literary gossip rather than on numismatics and epigraphy. The dean was an elegant scholar, and his rendering of the *Hypnerion of Keats* into Latin verse (1862) has received high praise.

See *Autobiography of Dean Merivale*, with selections from his correspondence, edited by his daughter, Judith A. Merivale (1889); and *Family Memorials*, by Anna W. Merivale (1884).

**MERIVALE, HERMAN** (1806-1874), English civil servant and author, elder brother of the preceding, was born at Dawlish, Devonshire, on the 8th of November 1806. He was educated at Harrow School, and in 1823 entered Oriel College, Oxford. In 1825 he became a scholar of Trinity College and also won the Ireland scholarship, and three years later he was elected fellow of Balliol College. He became a member of the Inner Temple and practised on the western circuit, being made in 1841 recorder of Falmouth, Helston and Penzance. From 1837 to 1842 he was professor of political economy at Oxford. In this capacity he delivered a course of lectures on the British Colonies in which he dealt with questions of emigration, employment of labour and the allotment of public lands. The reputation he secured by these lectures had much to do with his appointment in 1847 as assistant under-secretary for the colonies, and in the next year he became permanent under-secretary. In 1859 he was transferred to the permanent under-secretaryship for India, receiving the distinction of C.B. In 1870 Merivale was made D.C.L. of Oxford. He died on the 8th of February 1874. Besides his *Lectures on Colonization and Colonies* (1841), he published *Historical Studies* (1865), and completed the *Memoirs of Sir Philip Francis* (1867); he wrote the second volume of the *Life of Sir Henry Lawrence* (1872) in continuation of Sir Herbert Edwardes's work.

A tribute to his powers as an original thinker by his chief at the Colonial Office, Sir Edward Bulwer-Lytton, is printed with a notice of his career which his brother contributed to the *Transactions* (1884) of the Devonshire Association.

**MERKARA**, the capital of the province of Coorg, in Southern India, situated on a plateau about 4000 ft. above the sea. Pop. (1901), 6732. It consists of two quarters: the fort, containing the public offices, the old palace, and the residence of the commissioner; and the native town of Mahadevapat. Here are the headquarters of the Coorg and Mysore Rifles, a body of volunteers chiefly composed of coffee planters.

**MERLIN, ANTOINE CHRISTOPHE** (1762-1833), French revolutionist, called "of Thionville" to distinguish him from his namesake of Douai (see below), was born at Thionville on the 13th of September 1762, being the son of a procureur at the bailiwick of Thionville. After studying theology, he devoted himself to law, and in 1788 was an avocat at the parliament of Metz. In 1790 he was elected municipal officer of Thionville, and was sent by the department of Moselle to the Legislative Assembly. On the 23rd of October 1791 he moved and carried the institution of a committee of surveillance, of which he became a member. It was he who proposed the law sequestrating the property of the émigrés, and he took an important part in the émeute of the 20th of June 1792 and in the revolution of the 10th of August of the same year. He was elected deputy to the National Convention, and pressed for the execution of Louis XVI., but a mission to the army prevented his attendance at the trial. He displayed great bravery in the defence of Malma. He took part in the reaction which followed the fall of Robespierre, sat in the Council of the Five Hundred under the Directory, and in 1795 was elected an élu of the 18th Fructidor (Sept. 1795). He demanded the deportation of certain republican members. In 1798 he ceased to be a member of the Council of Five Hundred, and was appointed director-general of posts, being sent subsequently to organize the army of Italy. He retired into private life at the proclamation of the consulate, and lived in retirement under the consulate and the empire. He died in Paris on the 14th of September 1833.

**MERLIN, PHILIPPE ANTOINE**, COUNT (*1754-1838*), French politician and lawyer, known as Merlin "of Douai," was born at Arleux (Nord) on the 30th of October 1754, and was called to the Flemish bar in 1775. An indefatigable student, he collaborated in the *Répertoire de jurisprudence* published by J. N. Guyot, the later editions of which appeared under Merlin's superintendence, and also contributed to other important compilations. Elected to the states-general as deputy for Douai, he was one of the chief of those who applied the principles of liberty and equality embodied in the decree of the 4th of August 1789 to actual conditions. On behalf of the committee appointed to deal with feudal rights, he presented to the Convention reports on the seigniorial rights which were subject to compensation, on hunting and fishing rights, forestry, and kindred subjects. He carried legislation for the abolition of primogeniture, secured equality of inheritance between relations of the same degree, and between men and women.

His numerous reports to the Constituent Assembly were supplemented by popular exposition of current legislation in the *Journal de législation*. On the dissolution of the Constituent Assembly he became judge of the criminal court at Douai. He was no advocate of violent measures; but, as deputy to the Convention, he voted for the death of Louis XVI., and as a member of the council of legislation he presented to the Convention on the 17th of September 1793 the infamous law permitting the detention of suspects. He was closely allied with his namesake Merlin "of Thionville," and, after the counter-revolution which brought about the fall of Robespierre,
he became president of the Convention and a member of the Committee of Public Safety. His efforts were primarily directed to the prevention of any recurrence of the tyranny exercised by the Jacobin Club, the commune of Paris, and the revolutionary army. He persuaded the Committee of Safety to take upon itself the closing of the Jacobin Club, on the ground that it was an administrative rather than a legislative measure. He recommended the readmission of the survivors of the Girondin party to the Convention, and drew up a law limiting the right of insulation; he had also a considerable share in the foreign policy of the victorious republic. With Cambacérès he had been commissioned in April 1794 to report on the civil and criminal legislation of France, with the result that after eighteen months' work he produced his Rapport et projet de code des délits et des peines (10 Vendémiaire, an. IV.). Merlin's code abolished confiscation, branding and imprisonment for life, and was based chiefly on the penal code drawn up in September 1791. He was made minister of justice (Oct. 30, 1795) under the Directory, and showed excessive rigour against the emigrants. After the coup d'état of the 18th Fructidor he became (Sept. 5, 1797) one of the five directors, and was accused of the majority of the government. He retired into private life (June 18, 1799), and had no share in the revolution of the 18th Brumaire. Under the consulate he accepted a modest place in the court of cassation, where he soon became procureur-général. Although he had no share in drawing up the Napoleonic code, he did more than any other lawyer to fix its interpretation. He became a member of the council of state, count of the empire, and grand officer of the Legion of Honour; but having resumed his functions during the Hundred Days, he was one of those banished on the second restoration. The years of his exile devoted to his Répertoire de jurisprudence (5th ed., 8 vols., Paris, 1827-1828) and to his Recueil alphabétique des questions de droit (4th ed., 8 vols., Paris, 1837-1838). At the revolution of 1830 he was able to return to France, where he re-entered the Institute of France, of which he had been an original member, being admitted to the Académie des Sciences Morales et Politiques. He died in Paris on the 26th of December 1838.

His son, Antoine François Eugène Merlin (1778-1854), was a well-known general in the French army, and served through most of Napoleon's campaigns.

See M. Mignet, Portraits et notices historiques (1852), vol. I.

MERLIN (Welsh, Myrddin), the famous bard of Welsh tradition, and enchanter of Arthurian romance. His history as related in this latter may be summarized as follows. The infernal powers, aghast at the blow to their influence dealt by the Incarnation, determine to counteract it, if possible, by the birth of an Antichrist, the offspring of a woman and a devil. As in the book of Job, a special family is singled out as subjects of the diabolic experiment, their property is destroyed, one after another, until Joseph of Arimathea, who has placed herself under the special protection of the Church, is left alone. The demon takes advantage of an unguarded moment of despair, and Merlin is engendered. Thanks, however, to the prompt action of the mother's confessor, Blaisey, at once baptizing the child of this abnormal birth, the mother truly protesting that she has had intercourse with no man, Merlin is claimed for Christianity, but remains dowered with demaic powers of insight and prophecy. An infant in arms, he saves his mother's life and confounds her accusers by his knowledge of their family secrets. Meanwhile Vortigern, king of the Britons, is in despair at the failure of his efforts to build a tower in a certain spot; however high it may be reared in a day, it falls again during the night. He consults his diviners, who tell him that the foundations must be watered with the blood of a child who has never had a father; the king accepts the advice of the last of the line of the descendent of such a prodigy. They come to the city where Merlin and his mother dwell at the moment when the boy is cast out from the companionship of the other lads on the ground that he had no father. The messengers take him to the king, and on the way astonish them by certain prophecies which are fulfilled to their knowledge. Arrived in Vortigern's presence, he at once announces that he is aware alike of the fate destined for him and of the reason, hidden from the magicians, of the fall of the tower. It is built over a lake, and beneath the waters of the lake in a subterranean cavern lie two dragons, a white and a red; when they turn over the tower falls. The lake is drained, the correctness of the statement proved, and Merlin's position as court prophet assured. Henceforward he acts as adviser to Vortigern's successors, the princes Ambrosius and Uther (subsequently Uther-Pendragon). As a monument to the Britons fallen on Salisbury Plain he brings from Ireland, by magic means, the stones now forming Stonehenge. He aids Uther in his passion for Ygwene, wife to the duke of Cornwall, by Merlin's spells Uther assumes the form of the husband, and on the night of the duke's death Arthur is engendered. At his birth the child is committed to Merlin's care, and by him given to Antor, who brings him up as his own; a much more extensive account of this episode is given in an "Epos" by G. de Nerval. This version, with the great cry, or Brail, which the magician uttered before his death, appears to have been the most popular. Another represents his prison as one of air; he is invisible to all, but can see and hear, and occasionally speak to passers by; thus he holds converse with the forms of animals. In the prose Perséval he retires voluntarily to an "Espeymore" reserved for the use of the wise man of man.

The curious personality of Merlin is now generally recognized as being very largely due to the prolific invention of Geoffrey of Monmouth. Nennius, upon whose Historia Geoffreyl enlarged and "improved," gives indeed the story of Vortigern and the tower, but the boy's name is Ambrosius. Geoffrey calls him Merlin-Ambrosius, a clear proof that he was adapting Nennius's story. He represents the saqū in his rôle of court diviner, his "Prophétie" being incorporated in later manuscripts of the Historia. Subsequently Geoffrey enlarged on the theme, composing a Vita Merlini in which we find the magician in the rôle of a "possessed" wood-abider, fleecing the haunts of men, and consort ing with beasts. This gave rise to the idea that there had originally been two Merlins, Merlin-Ambrosius and Merlin-Sylvester, a view now discarded by the leading scholars. The Vita was so successful that Geoffrey obtained as reward the bishopric of St Asaph.

Welsh vernacular literature has preserved a small but interesting group of poems, strongly national and patriotic in character, which are attributed to Merlin (Myrddin).

A few years after Geoffrey's death Merlin's adventures were amplified into a romance, the first draft of which is attributed to Robert de Boron, and which eventually took the form of a lengthy introduction to the prose Lancelot and cyclic redaction of the Arthurian legend.

The romantic, as distinguished from legendary or historical Merlin, exists in the following forms: (a) a fragmentary poem preserved in a unique manuscript of the Bibl. nat. (this gives no more than the introduction to the story); (b) a prose rendering of the above, of which a fair number of copies exist, generally found as in the original poem, coupled with a version of the early history of the Grail, known as Joseph of Arimathæa, and in two cases following Infundibulum and Mort Artus, thus forming a small cycle; (c) the Ordinary or Vulgate Merlin, a very lengthy romance, of which numerous copies exist (see Dr Sommer's edition); (d) and (e) two continuations to the above, each represented by a single manuscript, of which the "Grail" of the "Picts," and the "Grail," which was utilized for his translation, and also formed a part of the compilation used by the Spanish and Portuguese translators, and (e) a very curious manuscript, 337, Bibl. nat. (fonds Français), which Paulin Paris calls On Arthur's death, a much more extended version elsewhere.

M. La Villemarqué's "critical study" (Myrddin, ou l'enchaîneur, de la légende... ofallert elsewhere.)
Merlin, in 1861) cannot be regarded as much more trustworthy than Geoffrey himself. The story of the tower, and the Boy without a Father, has been critically examined by Dr Gaster, in a paper read before the Folk-Lore Society and subsequently published in Folk-Lore, Vol. X. Geoffrey's great which has been successful in 1898 contrary to the tale, and sees in it the germ of the whole Merlin legend. Alfred Nutt (Revue celtique, vol. xxvii.) is of the view that Aengus, the magician of the Irish Tuatha de Danaan, was also of Merlin, and it is possible that the idea of the Boy without a Father theme was generally associated with the Celtic magicians, and is the property of no one in particular. Some years ago the late Mr Ward of the British Museum drew attention to the Boy without a Father in the life of St Kentigern, relating the dialogue with a "possessed" being, a dweller in the woods, named Lailoken, and pointed out the practical identity of the adventures of that personage and those assigned by Geoffrey to Merlin in the Vita; the point was elaborated and the idea of the Man Who Lives Between the Walls (moerus). (See Romanic, vol. xxvii.). Ferd. Lot, in an examination of the sources of the Vita Merlini (Annales de Bretagne, vol. xv.), has pointed out the more original character of the "Lai-looken" fragments, and decides that Geoffrey knew the "Ecco" tradition and utilized it for his Vita. He also comes to the conclusion that the Welsh Merlin poems, with the possible exception of the Dialogue between Merlin and Taliesin, are posterior to, and inspired by, Geoffrey's work. So far the researches of scholars appear to have resulted in the fact that the legend of Merlin, as we know it, is of complex growth, combined from traditions of independent and widely differing origin. Most probably there is a certain substratum of fact beneath all; there may have been, there very probably were, men and women who lived, and were remembered as such; but this does not mean improbable that curious stories were told of his origin. It is worth noting that Layamon, whose translation of Wace's Brut is of so much interest, on account of the variants he introduces into the story of the Boy without a Father, would have been familiar with the idea of the Man Who Lives Between the Walls; the father is a glorious and supernatural being, who appears to the mother in her dreams. Layamon lived on the Welsh border, and the possibility of his variants being drawn from genuine British tradition is generally recognized. The poem relating the dialogue between Merlin and his brother bard, Taliesin, may also derive from genuine tradition. Further than this we can hardly venture to go; the probability is that anything more told of the character and deeds of this man has been, and is still, a fertile field of popularative powers and faculty of combination of Geoffrey of Monmouth. See also G. Paris and Ulrich (Société des anciens textes français, 1886); Merlin, ed. Wheatley (Early English Text Society, 1899); Aristotle and Merlin, ed. E. H. G. Smollett. (Merlin, in architecture, the solid part of an embattled parapet between the embrasures, sometimes pierced by loopholes. The word is French, adapted from Ital. merlone, possibly a shortened form of mergola, connected with Lat. mergus, pitchfork, or from a diminutive merulus, from merus (morsus), a wall.)

"Mermaids" and "Mermen," in the folk-lore of England and Scotland, a class of semi-human beings who have their dwelling in the sea, but are capable of living on land and of entering into social relations with men and women. They are easily identified, at least in some of their most important aspects, with the Old German Merminni or Meerfrau, the Icelandic Hafiga, Margygr, and Marmenill (mod. Marbenund), the Danish Hafmand or Maremind, the Irish Merrow or Merruach, the Marie-Morgan of Brittany and the Morforwyn of Wales; and they have various points of resemblance to the vodouyani or vodoun of the native African mythology. The typical mermaid has the head and body of a woman, usually of exceeding loveliness, but below the waist is fashioned like a fish with scales and fins. Her hair is long and beautiful, and she is often represented, like the Russian rusalka, combing it with one hand while in the other she holds a looking-glass. For a time at least a mermaid may become to all appearance an ordinary human being; and an Irish legend ("The Overlouing of Lough Neagh and Lisan an legnaud, and mered, a maid; but, though mere wif occurs in Beowulf, mere-maid does not appear till the Middle English period (Chaucer, "The Tale of the Rose," &c.). In Cornwall the fishermen say "mer-mer" and "merman." The connexion with the sea rather than with inland waters appears to be of later origin. The Mermaid of Martin Mere and the "Weir's Traditions of Lancashire," etc., is an example of the older force of the word; and such "mer-women" are known to the country-folk in various parts of England (e.g. at Newport in Shropshire, where the town is some day to be drowned by the woman's agency). See Rhys, "Welsh Fairy Tales," in Y Gymroddor (1881, 1882). The Mermaid," in Joyce's Old Celtic Romances) represents the temporary transformation of a human being into a mermaid. The mermaid legends of all countries may be grouped as follows. (a) A mermaid or mermaids either voluntarily or under compulsion reveal things that are about to happen. Thus the two mermaids (merewip) Hadeburg and Sigligist, in the Niebelungenlied, disclosed his future course to the hero Hagen, who, having got possession of their garments, which they had left on the shore, compels them to pay ransom in this way. According to Resenius, a mermaid appeared to a peasant of Sanssöe, foretold the birth of a prince, and moralized on the evils of intemperance, &c. (Kong Frederik's den andens Kronikke, Copenhagen, 1850, p. 302). (b) A mermaid imparts supernatural powers to a human being. Thus in the beautiful story of "The Old Man of Cury" (in Hunt's Popular Romances of the West of England, 1871) the old man, instead of silver and gold, obtains the power of doing good to his neighbours by breaking the spells of witchcraft, chasing away diseases, and discovering thieves. (c) A mermaid has come one under her, her connection, for wrong done to her, exacts a terrible penalty. One of the best and most detailed examples of this class is the story of the "Mermaid's Vengeance" in Hunt's book already quoted. (d) A mermaid falls in love with a human being, lives with him as his lawful wife for a time, and then, some pact being unwritten or intentionally broken by him, perishes, or even to her true home in the sea. Here, if its form be accepted, the typical legend is undoubtedly that of Médusine (q.v.), which, being made the subject of a romance by Jean d'Arras, became one of the most popular folk-books of Europe, appearing in Spanish, German, Dutch and Bohemian versions. (e) A mermaid falls in love with a man, and entices him to go to live with her below the sea; or a merman wins the affection or captures the person of an earlborn maiden. This form of legend is very common, and has naturally been a favourite with poets. Macphail of Colonsay successfully made Dermaid Bremasin, called the beautiful and excellent Mermaid, come back after long years of trial to the maid of Colonsay. The Danish ballads are especially full of the theme; as "Agnete and the Merman," an antecedent of Matthew Arnold's "Forsaken Mermaid," the "Deceitful Merman," or Merston's Daughter"; and the finely detailed story of Rosam Hafmand (No. 49 in Grimm). In relation to man the mermaid is usually of evil issue if not of evil intent. She has generally to be bribed or compelled to utter her prophecy or bestow her gifts, and whether as wife or paramour she brings disaster in her train. The fish-tail, which in popular fancy forms the characteristic feature of the mermaid, is really of secondary importance; for the true Teutonic mermaid—probably a remnant of the great cult of the Vanir—had no fish-tail; and this symbolic appendage occurs in the mythologies of so many countries as to afford no clue to its place of origin. The Tritos, and, in the later representations, the Sirens of classical antiquity, the Phoenician Dagon, and the Chaldæan Onæres are, all with known examples; the Ottavus and other American Indians have their man-fish and woman-fish (Jones, Traditions of the North American Indians, 1830); and the Chinese tell stories not unlike our own about the sea-women of their southern seas (Dennis, Folklore of China, 1875). Quasi-historical instances of the appearance or capture of mermaids are common enough, and serve, with the frequent use of the figure on signboards and coats of arms, to show how thoroughly the myth had taken hold of the popular imagination.

5 See the paper in Journ. Brit. Arch. Assoc., xxxviii., 1882, by H. S. Cunningham, which presents the view that mermaids or mermen occur in the arms of Eras Caledon, Howth and Sandwich, Viscounts Boyne and Hood, Lord Lyttelton and Scott of Abbotsford, as well as in those of the Ellis, Byron, Pené, Sheffield and other families. The English heralds represent the creatures with a single tail, the French and German heralds frequently with a double one.
A mermaid captured at Bangor, on the shore of Belfast Lough, in the 6th century, was not only baptized, but admitted into some of the old calendars as a saint under the name of Mergen. (Notes and Queries, Oct. 21, 1888; and Stowe (Annales, under date 1187) relates how a man-fish was kept for six months and more in the castle of Orford in Suffolk. As showing how legendary material may gather round a simple fact, the oft-told story of the sea-woman of Edam is particularly interesting. The oldest authority, Joh. Gerbrander a Leydis, a Carmelite monk (d. 1504), tells (Annales, &c., Frankfurt, 1620) how in 1403 a wild woman came through a breach in the dike into Purmerland, and, being found by some Edam milkmaids, was ultimately taken to Haarlem and lived there many years. Nobody could understand her, but she learned to spin, and was wont to adore the cross. Ockas Scharlensis (Chronik von Friesland, Leeuw., 1597) reasons that she was not a fish because she could spin, and she was not a woman because she could live in the sea; and thus in due course she got fairly established as a genuine mermaid. Voesmaer, who has carefully investigated the matter, enumerates forty writers who have repeated the story, and shows that the older ones speak only of a woman (see Beschor. der zoogoer, Mannin in der stad Haarlem," in Verh. van de Hess. Maatsch. van K. en Wet., part 23, No. 1786).

The best account of the mermaid-myth is in Baring-Gould's Myths of the Middle Ages. See also, besides works already mentioned, Pontoppidan, who in his logically credulous way collects much material to prove the existence of mermaids; Maillet, Telliaed (1804); Grumm. Deutsche Mythologien, i. 304, and Aldob. Heldenlieder (1811); Waldron's Description and Train's Hist. and Stat. of the Isle of Man; Folk-lore Society's Record, vol. ii.; Napier, Hist. and Trad. Tales connected with the South of Scotland; Selbst, Traditions de la haute Bretagne (1882), and Comtes des marins (1885).

MEROBADES, FLAVIUS (5th century A.D.), Latin rhetorician and poet, probably a native of Baetica in Spain. He was the official laureate of Valentinian III. and Aëtius. Till the beginning of the 10th century he was known only from the notice of him in the Chronicle (year 443) of his contemporary Iadius, where he is praised as a poet and orator, and mention is made of statues set up in his honour. In 1813 the base of a statue was discovered at Rome, with a long inscription belonging to the year 435 (C.I.L. vi. 1724) upon Flavius Merobaudes, celebrating his merits as warrior and poet. Ten years later, Niebuhr discovered some Latin verses on a palimpsest in the monastery of St. Gall, the authorship of which was traced to Merobaudes, owing to the great similarity of the language in that part of Italy and Spain. The first lines of a exactly piece known under the name of Merobaudes was a short poem (30 hexameters) De Christo, attributed to him by one MS., to Claudian by another; but Ebert is inclined to dispute the claim of Merobaudes to be considered either the author of the De Christo or a Christian. The "Panegyric" and minor poems have been edited by B. G. Niebuhr (1824); by I. Bekker in the Bonn Corpus scriptorum hist. Byz. (1836); the De Christo in T. Birt's Claudian (1842), where the name is not given. It is up to the classics A. Ebert, Geschichte der Literatur des Mittelalters im Abendlande (1898).

MEROE, the general name (as Island of Meroe) for the region bounded on three sides by the Nile (from Atbara to Khartum), the Atbara, and the Blue Nile; and the special name of an ancient city on the east bank of the Nile, 877 m. from Wadi Halfa by river, and 554 by the route across the desert, near the site of which is a group of villages called Bakarawiya. The site of the city is marked by over two hundred pyramids in three groups, of which many are in ruinous condition. After these ruins had been described by several travellers, among whom F. Caillaud (Voyage d'Egypte, Paris, 1826-1828) deserves special mention, some excavations were executed on a small scale in 1834 by G. Ferlinski (Cennó sugli scavi operati nella Nubia e catalogo degli oggetti ritrovati, Bologna, 1837), who discovered (or professed to discover) various antiquities, chiefly in the form of jewelry, now in the museums of Berlin and Munich. The ruins were examined in 1844 by C. R. Lepsius, who brought many plans, sketches and copies, besides actual antiquities, to Berlin. Further excavations were carried on by E. W. Budge in the years 1902 and 1904, the results of which are recorded in his work, The Egyptian Sudan: its History and Monuments (London, 1907). Troops were furnished by Sir Reginald Wingate, governor of the Sudan, who made paths to and between the pyramids, and sank shafts, &c. It was found that the pyramids were regularly built over sepulchral chambers, containing the remains of bodies either burned or buried without being mummi- fied. The most interesting objects found were the relics on the chapel walls, already described by Lepsius, and containing the names with representations of queens and some kings, with some chapters of the Book of the Dead; some stelae with inscriptions in the Meroitic language, and some vessels of metal and earthenware. The best of the relics were taken down stone by stone in 1905, and set up partly in the British Museum and partly in the museum at Khartum. In 1910, in consequence of a report by Professor Suyce, excavations were commenced in the mounds of the town and the necropolis by J. Garstang on behalf of the University of Liverpool, and the ruins of a palace and several temples were discovered, built by the Meroite kings. (See also ETHIOPIA.)

Meroe was probably also an alternative name for the city of Napata, the ancient capital of Ethiopia, built at the foot of Jebel Barkal. The site of Napata is indicated by the villages of Sanam Abu Dom on the left bank of the Nile and Old Merawi on the right bank of the Nile. Formerly thought to be built on the site of Sanam Dom and on the same side of the river, was founded by the Sudan government in 1905 and made the capital of the mudiria of Dongola. (D. S. M.)*

MEROVINGIANS, the name given to the first dynasty which reigned over the kingdom of the Franks. The name is taken from Merovech, one of the first kings of the Salian Franks, who succeeded to Clodio in the middle of the 5th century, and soon became the centre of many legends. The chronicler known as Frédugarius Scholasticus relates that a queen was once sitting by the seashore, when a monster came out of the sea, and by this monster she subsequently became the mother of Merovech, but this myth is due to an attempt to explain the hero's name, which means "the sea-born." At the great battle of Mauriac (the Catalanian fields) in which Attilius Magns and Goths were defeated, the subject of tragedies by Euripides (Cresphontes, not extant), Voltaire, Maffei and Matthew Arnold. (2) The daughter of Atlas and wife of Sisyphus. She was one of the seven Pleiades, but remained invisible, hiding her light for shame at having become the wife of a mortal (Apollo i. 9, 3; iii. 10, 1; Ovid, Fasti, iv. 175).

The "Panegyric" and minor poems have been edited by B. G. Niebuhr (1824); by I. Bekker in the Bonn Corpus scriptorum hist. Byz. (1836); the De Christo in T. Birt's Claudian (1842), where the name is not given. It is up to the classics A. Ebert, Geschichte der Literatur des Mittelalters im Abendlande (1898).
but none of them reached more than the age of twenty or twenty-five; this was the age of the "rosa fainante." Henceforth the real sovereign was the mayor of the palace. The mayors of the palace belonging to the Carolingian family were able to keep the throne vacant for long periods of time, and finally, in 751 the mayor Pippin, with the consent of the pope Zacharias, sent King Childeric III. to the monastery of St Omer, and shut up his young son Thierry in that of St Wandrille. The Merovingian race thus came to an end in the cloister.

Dahn, Die Könige der Germanen, vii. (Leipzig, 1894); build in the same author Urgeschichte der germanischen und romanischen Völker, iii. (Berlin, 1883); W. Schultz, Deutsche Geschichte von der Urzeit bis zu den Karolingern, ii. (Stuttgart, 1896).

Merovingian Legend.—It has long been conceded that the great French national epics of the 11th and 12th centuries must have been founded on a great deal of popular poetry, and that many of the episodes of the chansons de geste refer to historical events anterior to the Carolingian period. Floianon is obviously connected with the Gesta Dagoberti, and there are traces of the influence of popular songs on the Frankish heroes in Gregory of Tours and other chroniclers. See G. Kurth, Histoire du Paysage, 269; F. D. de Loys, De Floiana et autres fables gallo-romaines (Paris, 1866); G. van Voorst, Der Ursprung der väterlichen Geschichten des Petigride (2 vols., Leipzig, 1884); Guissard and H. Michel; P. Ragna, Dele Origine dell' epopea francese (Florence, 1884), with which cf. G. Paris in Romantia, xi. 1886, and his Geschichte der gallo-romischen Epoik (Leipzig, 1904); C. MERRILL, a city and the county-seat of Lincoln county, Wisconsin, U.S.A., 185 m. N.W. of Milwaukee, on both sides of the Wisconsin river. Pop. (1910 census), 8689. It is served by the Chicago, Milwaukee & St Paul railroad. The city is situated about 1270 ft. above the sea and has an invigorating climate. Brook trout and various kinds of game, including deer, abound in the vicinity. Grandfather Falls and the Dells of the Prairie river are picturesque places near the city, and furnish good water-power. The principal public building is the Lincoln county court house, and the city contains the T. B. Scott free library, a fine high-school, and the Ravn hospital, a private institution. Riverside Park is maintained by the corporation, and a park along the Prairie river is owned and maintained by the city. Merrill is an important hardwood lumber market, and its principal industry is the manufacture of lumber and lumber products. The manufacture of paper and paper pulp and of lathes is also important. In 1905 the factory products were valued at $3,260,638. There are granite quarries and brickyards in the vicinity. Merrill was settled in 1875, incorporated as a village in 1880, and chartered as a city in 1883.

MERRIMAC,1 a river in the north-eastern part of the United States, having its sources in the White Mountains of New Hampshire, and flowing south into Massachusetts, and thence east and north-east into the Atlantic Ocean. With its largest branch it has an extreme length of about 183 m. The Merrimac proper is formed at Franklin, New Hampshire, by the junction of the Pembroke and Winnipesaukee rivers. The former is the larger branch and rises in the White Mountains in Grafton county; the latter is the outlet of Lake Winnipesaukee. The valley of the Merrimac was formed during the glacial period and was filled with drift as the ice retreated; subsequently flow plain thus formed has been terraced and terraces have been formed, and at different places, where the new channel did not conform to the pre-glacial channel, the river has come upon buried ledges, relatively much more resistant than the drift below, and waterfalls have thus resulted. The river falls 269 ft. in a distance of 110 m. from Franklin to its mouth. The greater part of the total fall is at six points, and at each of four of these is a city which owes its importance in great measure to the water-power thus provided, Lowell and

1 The name is an Indian word said to mean "swift water." In popular usage the spelling " Merrimack " is used at places along the river above Haverhill.

Lawrence in Massachusetts, and Manchester and Concord in New Hampshire; at Lowell there is a fall of 30 ft. (Pawtucket Falls), and at Manchester there is a fall of 55 ft. (Amoskeag Falls). The region drained by the river is 453 sq. m. in extent, and contains a number of lakes, which together with some artificial reservoirs serve as a storage system. On the navigable portion of the river, which extends 174 m. above its mouth, are the cities of Newburyport, near its mouth, and Haverhill, at the head of navigation. In 1890-1908 the Federal government dredged a channel from Newburyport to Haverhill (14:5 m.) 7 ft. deep and 150 ft. wide at mean low water; vessels having a draft of 12:5 ft. could then pass over the outer bar of Newburyport.

MERRIMAN, HENRY SETON (d. 1903), the pen-name of Hugh Stowell Scott, English novelist. He was a member of the firm of Henry Scott & Sons, and was for some years an underwriter at Lloyd's. His literary career began in 1889 with The Phantom Future, and he made his first decided hit with his Russian story, The Sowers (1896), which was followed by many other well-constructed novels remarkable for excellence of plot and literary handling. The author was an enthusiastic traveller, many of his journeys being undertaken with his friend Stanley Weyman. He was about forty when he died at Melton, near Ipswich, on the 27th of November 1903. Among his works were Roden's Corner (1898); The Isle of Unrest (1899); In Kedron's Tents (1897); The Velvet Glove (1901); The Vultures (1902); Barlash of the Guard (1903); and The Last Hope (1904).

MERRITT, WESLEY (1836-1903), American soldier, was born in New York City on the 16th of June 1836. He graduated at West Point in 1856, and was assigned to the cavalry service. He served in Utah (1861) and in the defences of Washington (1862-65); learnt the field duties of his arm as aide to General Philip St George Cooke, who then commanded the cavalry of the Army of the Potomac; became brigadier-general, United States Volunteers, in June 1863; and in September 1863 was placed in command of a brigade of regular cavalry in the Army of the Potomac. He won great distinction in the Virginia campaigns of 1864-65 and in Sheridan's Valley campaign, being brevetted major-general of volunteers for his conduct at Winchester and Fisher's Hill, and brigadier-general of the regular army for his services at Five Forks. In the final campaign about Richmond he did such good service in command of a cavalry division that he was brevetted major general in the regular army and was promoted major-general of volunteers. With two other Federal commissioners he arranged with the Confederate commanders for the surrender of the Army of Northern Virginia. He was mustered out of the Volunteer Service in February 1866, and in July became lieutenant-colonel of the 8th cavalry in the regular army, being promoted gradually to major-general (1895). He served in the Big Horn and Yellowstone Indian campaigns (1876) and in the expedition to relieve the command of Major Thornton, who was killed in 1879 by the Utes; was superintendent at West Point (1882-87); and commanded the military department of Missouri in 1887-95, and that of the Atlantic in 1897-98. He was assigned in May 1898 to the command of the United States forces that were sent to the Philippines, after Admiral Dewey's victory; stormed Manila on the 13th of August; and was military governor of the islands until the 30th of August, when he left Manila, which he joined the peace commission. From 1890 until his retirement from active service in June 1900 he commanded the Department of the East.

MERSEBURG, a town of Germany, in the Prussian province of Saxony, on the river Saale, 10 m. by rail S. of Halle and 15 m. W. of Leipzig. Pop. (1905), 20,024. It consists of a quaint and irregularly built old town, a new quarter, and two extensive suburbs, Altenburg and Neumarkt. The cathedral, which was restored in 1884-86, has a choir, a crypt and two towers of the 11th, a transept of the 13th and a late Gothic nave of the 16th century. Among its numerous monuments is one to Rudolph of Swabia, the rival of the emperor Henry IV. It contains
a great organ dating from the 17th century. Near the cathedral is the Gothic palace, formerly the residence of the bishops of Meissen, and now used as public offices. The town hall, and the Ständehaus, where the meetings of the provincial estates were held, are also noteworthy buildings. The industries include the manufacture of machinery, paper and celluloid, and tanning and brewing.

Meissen is one of the oldest towns in Germany. From 968 until the Reformation, it was the seat of a bishop, and in addition to being for a time the residence of the margraves of Meissen, it was a favourite residence of the German kings during the 10th, 11th and 12th centuries. Fifteen diets were held here during the middle ages, when its fair enjoyed the importance which was afterwards transferred to those of Leipzig. The town suffered severely during the Peasants' War and also during the Thirty Years' War. From 1657 to 1738 it was the residence of the dukes of Saxe-Meissen.

See E. Hoffmann, "Historische Nachrichten aus Alt-Merseburg" (Mersburg, 1903).

**Mersen (Meerssen), Treaty of**, a treaty concluded on the 8th of August 870 at Mersen, in Holland, between Charles the Bald and his half-brother, Louis the German, by which the kingdom of their nephew Lothair II. (d. 869) was divided between them. Charles received a portion of the kingdom of Lothair afterwards called Lorraine, extending from the mouths of the Rhine to Toul, together with the town of Besançon, the Lyonnais, the Viennais, the Vivarais, and the Uzège, i.e., the lands acquired by Lothair II. in 863 at the death of his brother Charles of Provence; while Louis had the cities of Cologne, Trier and Metz, together with Alsace, the Escuens, and the Varais, i.e. the greater part of the diocese of Besançon. The boundary between the two realms was marked approximately by the valleys of the Meuse and Moselle and by the Jura. Great importance has been attached to the determination of this frontier by some historians, who consider that it coincided with the dividing line between the Teutonic and Romance races and languages; but nothing is known of the bases upon which the negotiations were effected, and the situation created by this treaty came to an end in 879.

**Merseburg, Marple, and Glossop, watering the narrow Longdendale in which are several reservoirs for the Manchester water supply. The Mersey thus drains a large part of the Peak district of Derbyshire and of the southern portion of the Pennine system. The general direction from Marple is westerly. At Stockport the river Tame joins from the north, rising in the moors to the north-east of Oldham, and the Mersey soon afterwards debouches upon the low plain to the west of Manchester, which lies on its northern tributary the Irwell. The Bollin joins from the south-east near Heathly, and the main river, passing Warrington, begins to expand into an estuary before reaching Runcorn and Widnes, which face each other across it. The estuary, widening suddenly at the junction of the Weaver from the south-east, 23 m. below Runcorn, is 3 m. wide off Ellesmere Port, but narrows to less than ½ m. at Liverpool, and hardly exceeds a mile at the mouth in the Irish Sea. The fall of the Mersey is about 1600 ft. in all and about 300 ft. from Marple; its length, including the Goyt, is 70 m. exclusive of lesser windings, and it drains an area of 1596 sq. m. The estuary is one of the most important commercial waterways in the world. (See Liverpool and Birkenhead.) The Manchester Ship Canal (q.v.) joins the estuary through Eastham Locks, skirts its southern shore up to Runcorn, and crosses the river several times. From the name of the river was taken the title of Lord Mersey in 1910 by Sir John Bigham (b. 1840), on his elevation to the peerage after serving as a judge of the high court from 1897 to 1909 and president of the divorce court 1909–1910.

**Mersina**, a town on the south-eastern coast of Asia Minor, and capital of a sanjak in the vilayet of Adana. Pop. about 15,000 including many Christians, Armenian, Greek and European. Its existence as a port began with the siting up of the harbour of Tarsus and Pompeipolis, east and west, in the early middle ages; but it did not rise to importance till the Egyptian occupation of Cilicia (1832). It is now the busiest port on the south coast, being the terminus of the railway from Tarsus to Adana, by which (but still more by the course of the rich “Alien” plain comes down. It is served by most of the Levantine steamship companies, and is the best point of departure for visitors desiring to see Tarsus, the Cilician remains, and the finest scenery of the East Taurus. There is, however, no enclosed harbour, but only a good jetty. The making of a breakwater has long been under consideration. The anchorage in the roadstead is good, but the bay shoals for a long way out, and is exposed to swell from south-west and south. Mersina is an American mission centre, and the seat of a British vice-consul. Like all lowland Cilicia, it has a notoriously bad summer climate, and all inhabitants, who can do so, migrate to stations on the lower slopes of Taurus.

(D. G. H.)

**Meryth Tydfil, of Meryth Tydivil**, a municipal, county and parliamentary borough, and market-town of Glamorgan, south Wales, situated in a bleak and hilly region on the river Taff, on the Glamorganshire Canal, and the Brecon and Merthyr, Great Western, North Western, Taff Vale and Rhydymyn railways, 25 m. N.N.W. of Cardiff, 30 E.N.E. of Swansea, and 176 from London. Pop. (1901), 60,228. The town is said to have derived its name from the mythical of St. Tydfil, daughter of Brychan, who was put to death by Saxons in the 5th century. It is for the most part irregularly built and was formerly subject to severe epidemics due to defective sanitation; but it now possesses a supply of the purest water from the lesser Taff on the southern slope of the Breconshire Beacons. The town owes its early industrial prosperity to the abundant ironstone and coal of the district, and it thus became at an early date the chief seat of the iron industry in Wales. Four great ironworks were established here between 1759 and 1782. With the earliest, that of Dowlais, the Guest family were associated, first as partners and later as sole owners from 1782 to 1901 when the works were disposed to the company of Guest, Keen and Nettlefold. In 1765, Cyfarthfa was started by Anthony Bacon, and when firmly established, sold in 1794 to Richard Crawshay by whose descendants the works were
carried on till the owners formed themselves in 1820 into a limited company (Cruchshank Brothers Cyfartha Limited), the controlling interest in which has since been acquired by the Dowlais Company. The Plymouth works, started soon after Cyfartha, by Wilkinson and Guest, passed later into the hands of Anthony Hill from whose descendants they were purchased in 1863. They were closed down in 1882, but the collieries belonging to them continue to be worked on a large scale, yielding over 2000 tons of coal a day. The fourth great ironworks were those of Pen-y-darran which were carried on from 1782 to 1859. It was at Dowlais (in 1856) that Bessemer steel was first rolled into rails, but the use of puddled iron was not wholly abandoned at the works till 1882. It has now eighteen blast furnaces, and extensive collieries are also worked by the company, and large branch works were opened on the sea-board at Cardif in 1891. Cyfartha was converted into steel works in 1883. The iron from the main blast furnace is still exported from Spain. Merthyr Vale is almost entirely dependent on coal-mining and has one of the largest collieries in south Wales (Nixon's Navigation). The population of this district more than quintupled between 1881 and 1901.

From 1830 the government of the town was vested in a local board of health which in 1894 became an urban district council; by charter granted on the 5th of June 1905, it was vested in a corporation consisting of a mayor, 8 aldermen and 24 councillors. It was made a county borough from the 1st of April 1908. It comprises about 17,750 acres, is divided into eight wards and besides the older town, it includes Penydarren (1 m. N.E.), Dowlais (2 m. N.E.), Plymouth (1 m. S.) and Merthyr Vale (5 m. S.). It has a separate commission of the peace, and in conjunction with Aberdare and Mountain Ash, has had a stipendiary magistrate since 1829. The parliamentary borough which was created and given one member in 1832 and a second in 1867, includes the parish of Aberdare and parts of the parishes of Llanwonno, Merthyr Tydfil and Vainor (Brecon).

There is an electric tramway (completed in 1901) from the town to Cefn and Dowlais. In 1901 about 50% of the population above three years of age spoke both Welsh and English, 71% spoke Welsh only, and the remainder English only. The ancient parish of Merthyr Tydfil has been divided into five ecclesiastical parishes (Merthyr, Cyfartha, Dowlais, Pontbach, and Penydarren) and part of another parish (Treherrials). These six parishes form the rural deanery of Merthyr in the archdeaconry and diocese of Llandaff, and in 1909 it had 22 churches and 3 chapels. A magnificent dressed stone (Artbeu) has been built into the east wall of the parish church; and two other inscribed stones removed from Abercraf Farm in the greater Taff valley now lie in the parish churchyard. The old structure of the parish church has been entirely removed except the base of the tower. There is a Roman Catholic church in Penydarren Park and another at Dowlais. The Nonconformists, of which the chief denominations are the Baptists, Congregationalists and Methodists—Wesleyan and Calvinistic—had in 1906 82 chapels, 49 of which were used for Welsh services and 33 for English.

The public buildings include, besides the churches, a town hall and law courts (1898), drill hall (1866), library, market house, a county intermediate school, general hospital built in 1882, and enlarged in 1897, and an isolation fever hospital; a theatre (1894) and a fountain presented by Sir W. T. Lewis as a memorial to the pioneers of the town’s industry. At Dowlais there are public baths (1900) and a free library which have been provided by the owners of the Dowlais Works, Oddfellows' hall (1878), and a fever hospital (1860). At Thomas Town there is a recreation ground of 16 acres, formed in 1902. In 1908 the corporation purchased Cyfartha Castle (formerly the residence of the Crawshay family) and built on a park of 62 acres including a lake of 6 acres.

The Roman road from Cardiff and Gelligar to Brecon passed through Merthyr and the remains of a supposed fort were discovered in Penydarren park in 1882. Three miles to the north of Merthyr, on a limestone rock about 470 ft. above the lesser (eastern) Taff are the ruins of Mortlais Castle, built about 1280 by Gilbert de Clare on the northern limits of his lordship of Glamorgan, its erection causing a serious feud between him and de Bohun, earl of Hereford, who claimed its site as part of the lordship of Brecknock.

**MERULA—MERUV**

**MERULA, GEORGIUS** (the Latinized name of GIOACCHINO MIRIANI; c. 1430—1494), Italian humanist and classical scholar, was the son of Alessandro and Francesca. Almost all his life was spent at Venice and Milan, where he held a professorship and continued to teach until his death. To Merula we are indebted for the editio princeps of Plautus (1472), of the *Scriptores rei rusticae*, Cato, Varro, Columella, Palladius (1472) and possibly of Martial (1471). He also published commentaries on portions of Cicero (especially the *De finibus*), on Ausonius, Juvenal, Curtius Rufus, and other classical authors. He wrote also *Bellum scoerense* (1474), on account of the siege of Scodra (Scutari) by the Turks, and *Antiquitates vicicomm vitum*, the history of the Visconti, dukes of Milan, down to the death of Matteo the Great (1322). He violently attacked Politian (Poliziana), whose Miscellanea (a collection of notes on classical authors) were declared by Merula to be either plagiarized from his own writings or, when original, to be entirely incorrect.

See further by C. Giusti, *Giorgio Meru* (1789), with bibliography; for the quarrel with Politian see also C. Meiners' *Lebensbeschreibungen der berühmten Männer* (1796), ii. 138.

**Merv, Meru or Mard**, an oasis and town of Asia, in the Transcaspian province of Russia. The oasis is situated on the S. edge of the Kara-kum desert, in 37° 30' N. and 62° E. It is about 230 m. N. from Herat, and 280 S.S.E. from Khiva. Its area is about 1900 sq. m. The great chain of mountains which, under the names of Paropamisus and Hindu-Kush, extends from the Caspian to the Pamirs is interrupted some 180 m. south of Merv. Through or near this gap flow northwards in parallel courses the rivers Heri-rud (Tejend) and Murgah, until they lose themselves in the desert of Kara-kum. Thus they from the Merv a sort of watch tower over the entrance into Afghanistan on the north-west and at the same time create a stepping-stone or *steppe* between north-east Persia and the states of Bokhara and Samarkand. The present inhabitants of the oasis are Turkomans of the Tekke tribe. In 1897 they numbered approximately 240,000. The oasis is irrigated by an elaborate system of canals cut from the Murgah. The country has at all times been renowned throughout the East for its fertility. Every kind of cereal and many fruits grow in great abundance, e.g. wheat, millet, barley and melons, also rice and cotton. Silkworms are bred. The Turkomans possess a famous breed of horses and keep camels, sheep, cattle, asses and mules. They are excellent workers in silver and gold, and are skilled in the use of carpets and felts which are superior to the Persian. They also make feltz and a rough cloth of sheep's wool. The heat of summer is most oppressive. The least wind raises clouds of fine dust, which fill the air, render it so opaque as to obscure the noonday sun, and make respiration difficult. In winter the climate is very fine. Snow falls rarely, and when it does, it melts at once. The annual rainfall rarely exceeds 5 in., and there is often no rain from June till October. While in summer the thermometer goes up to 97° F., in winter it descends to 19° 5. The average yearly temperature is 60°. Here is a Russian imperial domain of 438 sq. m., artificially irrigated by works completed in 1895.

History.—In Hindu (the Parasi), Pans and Arab tradition, Merv is looked upon as the ancient Paradise, the cradle of the Aryan families of mankind, and of the human race. In the eleventh century the name of Mouru this place is mentioned with Bakhdi (Balkh) in the geography of the Zend-Avesta (Vendidad, ed. Spiegel, 1852-1863), which dates probably from at least 1200 B.C. Under the name of Margu it occurs in the cuneiform (Behistun) inscriptions of the Persian monarch Darius Hystaspis, where it is referred to as forming part of one of the satrapies of the ancient Persian Empire. It afterwards became a province (Margiana) of the Graeco-Syrian, Parthian and Persian kingdoms. On the Margus—the Epardus of Arrian and now the Murgah—stood the capital of the district, Antiochia Margiana, so called after Antiochus Soter, who rebuilt the city founded by Alexander the Great.
About the 5th century, during the rule of the Persian Sassanian dynasty, Merv was the seat of a Christian archbishopric of the Nestorian Church. The town was occupied (A.D. 646) by the lieutenants of the caliph Othman, and was constituted the capital of Khorasan. From this city as their base the Arabs, under Kotaiba (Qotaiba) ibn Moslem, early in the 8th century brought under subjection Balkh, Bokhara, Ferghana and Kashgaria, and penetrated into China as far as the province of Kan-suh. In the latter part of the 9th century Merv became obnoxious to Islam as the centre of heretical propaganda preached by Mokanna (g.v.). In 874 Arab rule in Central Asia came to an end. During their dominion Merv, like Samarkand and Bokhara, was one of the great schools of learning, and the celebrated historian Yaqut studied in its libraries. In 1040 the Seljuk Turks crossed the Oxus from the north, and having defeated Masud, sultan of Ghazni, raised Toghrul Beg, grandson of Seljuk, to the throne of Persia, founding the Seljukian dynasty, with its capital at Nishapur. A younger brother of Toghrul, Daud, took possession of Merv and Herat. Toghrul was succeeded by his nephew Alp Arslan (the Great Lion), who was buried at Merv. It was about this time that Merv reached the zenith of her glory. During the reign of Sultan Sanjar or Sinjar of the same house, in the middle of the 11th century, Merv was overrun by the Turkish tribes of the Ghiyathids, but the Khivans eventually passed under the sway of the rulers of Khwarizm (Khiva).

In 1221 Merv opened its gates to Tule, son of Jenghiz Khan, chief of the Mongols, on which occasion most of the inhabitants are said to have been butchered. From this time forward the city began to decay. In the early part of the 14th century the town was made the seat of a Christian archbishopric of the Eastern Church. On the death of the grandson of Jenghiz Khan Merv was included (1380) in the possessions of Timur-i-Leng (Tamerlane), Mongol prince of Samarkand. In 1505 the city was occupied by the Uzbegs, who five years later were expelled by Ismail Khan, the founder of the Safavid dynasty of Persia. Merv remained in the hands of Persia until 1787, when it was captured by the emir of Bokhara. Seven years later the Bokharians razed the city to the ground, broke down the dams, and converted the district into a waste. When Sir Alexander Burnes traversed the country in 1832, the Khivans were the rulers of Merv. About this time the Tekke Turkomans, then living on the Heri-rud, were forced by the Persians to migrate northwards. The Khivans contested the advance of the Tekkes, but ultimately, about 1836, the latter became the sovereign power in the country, and remained so until the Russians occupied the oasis in 1883.

The ruins of Old Merv cover an area of over 15 sq. m. They consist of a square citadel (Bairam Ali Khan kalak), 14 m. in circuit, built by a son of Tamerlane and destroyed by the Bokharians, and another kalak or walled enclosure known as Abdullah Khan. North from these lies the old capital of the Seljus, known as Sultan Kalak, and destroyed by the Mongols in 1219. Its most conspicuous feature is the burial mosque of Sultan Sanjar, reputedly dating from the 12th century. East of the old Seljuk capital is Giaur Kalak, the Merv of the Nestorian era and the capital of the Arab princes. North of the old Seljuk capital are the ruins of Iskender Kalak, probably to be identified with the ancient Merv of the Seleucid dynasty.

New Merv, the present chief town of the oasis, located in the first quarter of the 19th century, is on the Transcaspian railway, 380 m. by rail south-west from Samarkand. It stands on both banks of the Murghab, 90 ft. above the Caspian. First (1857), 1877, including Russians, Armenians, Turkomans, Persians and Jews. It has a meteorological observatory, 196 sq. m. of standing corn, raw cotton, hides, wool, nuts and dried fruit are exported.

MERX, ADALBERT (1838-1900), German theologian and orientalist, was born at Bleicherode near Nordhausen on the 2nd of November 1838. He studied at Jena, where he became extraordinary professor in 1869. Subsequently he became ordinary professor of philosophy at Tübingen, and in 1873 professor of theology at Giessen. From 1875 till his death he was professor of theology at Heidelberg. In the course of his researches he made several journeys in the East. Among his many works are: Grammatica syriaca (1867-1879); Vocabulary of the Tigré language (1868); Das Gedicht vom Hioh (1871); Die Prophetie des Joel and ihre Ausleger (1879); Die Saadionische Übersetzung der Hohenlieder ins Arabische (1882); Christomathia turcumica (1888); Historia artis grammaticae apud Syros (1889); Ein samaritanisches Fragment (1893); Idee und Grundzüge einer allgemeinen Geschichte der Mystik (1893). Merx devoted much of his later research to the elucidation of the Sinaic palimpsest discovered in 1892 by Mrs Agnes Smith Lewis (see BIBLE, IV. 321, ad fin.), the results being embodied in Die vier kanonischen Evangelien nach ihrem ältesten bekannten Texte (1897-1905). His last work was an edition of the books of Moses and Joshua. He died at Heidelberg on the 6th of August 1900.

MÉRONY, CHARLES (1821-1868), French etcher, was born in Paris in 1821. His father was an English physician, his mother a French dancer. It was to his mother's care that Mérony's childhood was confided. But she died when he was still young, and Mérony entered the French navy, and in the corvette Le Rhin "made the voyage round the world." He was then a journeyman in a lithographic warehouse. In 1856 he made pencil drawings which he was able to employ, years afterwards, as studies for etchings of the landscape of those regions. The artistic instinct developed, and, while he was yet a lieutenant, Mérony left the havy. Finding that he was colour-blind, he determined to devote himself to etching. He entered the work room of one Bléry, from whom he learned something of technical matters, and to whom he always remained grateful. Mérony was by this time poor. It is understood that he might have had assistance from his kindred, but he was too proud to ask it. And thus he was reduced to the need of executing for the sake of daily bread much work that was mechanical and irksome. Among learners' work, done for his own advantage, are to be counted some studies after the Dutch etchers such as Zeeman and Adrian van de Velde. Having proved himself a surprising copyist, he proceeded to labour of his own, and began that series of etchings which are the greatest embodiments of his greatest conceptions—the series called "Eaux-fortes sur Paris." These plates, executed from 1850 to 1854, are never to be met with as a set; they were never expressly published as a set. But they form the less constituted in Meryon's mind an harmonious series.

Besides the twenty-two etchings "sur Paris," characterized below, Mérony did seventy-two etchings of one sort and another—ninety-four in all being catalogued in Wedmore's Mérony and Mérony's Paris; but these include the works of his apprenticeship and of his decline, adroit copies in which his best success was in the sinking of his own individuality, and more or less dull portraits. Yet among the seventy-two prints outside his professed series there are at least a dozen that will aid his fame. Three or four beautiful etchings of Paris do not belong to the series at all. Two or three etchings, again, are devoted to the illustration of Bourges, a city in which the old wooden houses were as attractive to him for their own sakes as were the stone-built monuments of Paris. But generally it was when Paris engaged him that he succeeded the most. He would have done more work, however—though he could hardly have done better work—if the material difficulties of his life had not pressed upon him and shortened his days. He was a bachelor, unhappy in love, and yet, it is related, almost as constantly occupied with artistic work. The depth of his imagination and the surpassing mastery which he achieved almost from the beginning in the technicalities of his craft were appreciated only by a few artists, critics and connoisseurs, and he could not sell his etchings; or could sell them only for about rod. apiece. Disappointment told upon him, and, frugal as was his way of life, poverty must have affected him. He became subject to hallucinations. Enemies, he said, waited for him at the corners of the streets; his few friends robbed him or owed him that which they would
never pay. A few years after the completion of his Paris series, he was lodged in the madhouse of Charenton. Its order and care restored him for a while to health, and he came out and did a little more work, but at bottom he was exhausted. In 1867 he returned to his asylum, and died there in 1868. In the middle years of his life, just before he was placed under confinement, he was much associated with Bracquemond and with Flameng,—skilled practitioners of etching, while he was himself an undeniable genius—and the best of the portraits we have of him is that one by Bracquemond under which the sitter wrote that it represented "the sombre Méryon with the grotesque visage."

There are twenty-two pieces in the Eaux-fortes sur Paris. Some of them are insignificant. That is because ten out of the twenty-two were destined as headpiece, tailpiece, or running commentary on some more important plate. But each has its value, and certain of the smaller pieces throw great light on the aim of the entire set. Thus, one little plate—not a picture at all—is devoted to the record of verses made by Méryon, the purpose of which is to lament the life of Paris. The misery and poverty of the town Méryon had to illustrate, as well as its splendour.

The art of Méryon is completely misconceived when his etchings are spoken of as views of Paris. They are often "views," but they are so just so far as is compatible with their being likewise the visions of a poet and the compositions of an artist. It was an epic of Paris that Méryon determined to make, coloured strongly by his personal sentiment, and affected here and there by the occurrences of the moment—in more than one case, for instance, he hurried with particular affection to etch his impression of some old-world building which was on the point of destruction. Nearly every etching in the series is an instance of technical skill, but even the technical skill is exercised most happily in thoseetchings which have the advantage of impressive subjects, and which the collector willingly cherishes for their mysterious suggestiveness or for their pure beauty. Of these, the Abside de Notre Dame is the general favourite; it is commonly held to be Méryon's masterpiece. Light and shade play wonderfully over the great fabric of the church, seen over the spaces of the river. As a draughtsman of architecture, Méryon was complete; his sympathy with its various styles was broad, and his work on its various styles unbiased and of equal perfection—apoint in which it is curious to contrast him with Turner, who, in drawing Gothic, often drew it with want of appreciation. It is evident that architecture must enter largely into any representation of a city, however much such representation may be a vision, and however little a chronicle. Besides, the architectural portion even of Méryon's labour is but indirectly imaginative; to the imagination he has given freer play in his dealings with the figure, whether the people of the street or of the river or the people who, when he is most frankly or even wildly symbolical, crowd the sky. Generally speaking, his figures are, as regards draughtsmanship, "landscape-painter's figures." They are drawn more with an eye to melodrama than for academic correctness. But they are not "landscape-painter's figures" at all when what we are concerned with is not the method of their representation but the purpose of their introduction. They are seen then to be in exceptional accord with the sentiment of the scene. Sometimes, as in the case of La Morgue, it is they who tell the story of the picture. Sometimes, as in the case of La Rue des Mauvais Garçons—with the two passing women bent together in secret converse—they at least suggest it. And sometimes, as in L'Arche de Pont Notre Dame, it is their expressive gesture and eager action that give vitality and animation to the scene. Dealing perfectly with architecture, and perfectly, as far as concerned his peculiar purpose, with humanity in his art, Méryon was little called upon by the character of his subjects to deal with Nature. He drew trees but badly, never representing foliage happily, either in detail or in mass. But to render the characteristics of the city, it was necessary that he should know how to portray a certain kind of tree—river-water, mostly sluggish—and a certain kind of sky—the grey obscured and lower sky that broods over a world of roof and chimney. This water and this sky Méryon is thoroughly master of; he notes with observant affection their changes in all lights.

Méryon's excellent draughtsmanship, and his keen appreciation of light, shade and tone, were, of course, helps to his becoming a great etcher. But a living authority, himself an eminent etcher, and admiring Méryon thoroughly, has called Méryon by preference a great original engraver—so little of Méryon's work accords with Sir Seymour Haden's view of etching. Méryon was anything but a brilliant sketcher; and, if an artist's success in etching is to be gauged chiefly by the rapidity with which he records an impression, Méryon's success was not great. There can be no doubt that his work was laborious and deliberate, instead of swift and impulsive, and that of some other virtues of the etcher—"selection" and "abstraction" as Hamerton has defined them—he shows small trace. But a genius like Méryon is a law unto himself, or rather in his practice of art he makes the laws by which art and he are to be judged. It is worth while to note the extraordinary enhancement in the value of Méryon's prints. Probably of no other artist of genius, not even of Whistler, could there be cited within the same period a rise in prices of at all the same proportion. Thus the first state of the "Strage"—that with the verses,—selling under the beginning of 1873 for £5, sold under the middle of 1875 for £70. The first state of the "Galérie de Notre Dame," selling in 1873 for £5, and at M. Wassé's sale in 1880 for £11, fetched in 1905, £52. A "Tour de l'horloge," which two or three years later fetched a first impression of £100 and was fetched for £70. A first state (Wedmore's, not of course M. Delteil's first state, which, like nearly all his first states, is in fact a trial proof) of the "Saint Étienne du mont," realizing about £2 at M. Burty's sale, was realized £60 at a sale in May 1906. The second state of the "Morgue" (Wedmore) sold in 1905 for £65; and Wedmore's second of the "Abside," which used to sell throughout the seventies for £4 or £5, reached in November 1906 more than £200. At no period have even Dürer and Rembrandt seen their plates sold so swiftly and readily.

MESA (Span. mesas, from Lat. mensa, a table), in geographical hightable-land capped with hard rock, being the remnant of a former plateau. This type is general where strata are horizontal. In the process of denudation the hard rock acts as a flat protective cap preserving the regions between stream valleys or other places where denudation is especially active, in the form of "table-mountains" or "fortress-hills." Many examples are found in Spain, North and South Africa, the Bad Lands and Colorado regions of North America, in Arabia, India and Australia.

MESHCHERYAKS, or Meshchers, a people inhabiting eastern Russia. They are regarded as the Finns, and even now part of the Mordvinians (of Finnish origin) call themselves Meshchers. Klaproth, on the other hand, supposed they were a mixture of Finns and Turks, and the Hungarian traveller Regul discovered that the tatarized Meshchers of the Obi closely resembled Hungarians. They formerly occupied the basin of the Oka (where the town Meshchersk, now Meshchovsk, has maintained their name) and of the Sura, extending north-east to the Volga. After the conquest of the Kazan Empire by Russia, part of them migrated north-eastwards to the basins of the Kama and Byelaya, and thus the Meshchers divided into two branches. The western branch became Russified, so that the Meshcheryaks of the governments of Penza, Saratov, Ryazan and Vladimir have adopted the customs, language and religion of the conquering race; but their ethnographical characteristics can be easily distinguished in the Russian population of the governments of Penza and Tambo. The eastern branch has taken on the customs, language and religion of Bashkirs, with whom their fusion is still more complete.

MESHED (properly Mash-had, "the place of martyrdom"), capital of the province of Khorasan in Persia, situated in a plain watered by the Khashrud (Tortoise river), a tributary of the
Without the pilgrims who come to visit it, Meshed would be a poor place, but lying on the eastern confines of Persia, close to Afghanistan, the Russian Central Asia and Transcaspia, at the point where a number of trade routes converge, it is very important politically, and the British and Russian governments have maintained consulates-general there since 1859. Meshed had formerly a great transit trade to Central Asia, of European manufactures, mostly Manchester goods, which came by way of Trebizond, Tabriz and Teheran; and of Indian goods and produce, mostly muslins and Indian and green teas, which came by way of Bander Abbas. With the opening of the Russian railway from the Caspian to Merv, Bokhara and Samarkand in 1886–1887, Russian manufacturers were enabled to compete in Central Asia with their western rivals, and the value of European manufactures passing Meshed in transit was much reduced. In 1894 the Russian government enforced new customs regulations, by which a heavy duty is levied on Anglo-Indian manufactures and produce, excepting pepper, ginger and drugs, imported into Russian Asia by way of Persia; and the importation of green teas is altogether prohibited except by way of Batum, Baku, Uzunada and the Transcaspian railway. Since then the trade which Meshed had practically nil. In 1890 General Maclean, the British consul-general, reported that there were 650 silk, 40 carpet and 320 shawl looms at work. The carpet-looms at work now number several hundreds, while looms of silk and shawl number less than half what they did in 1890.

MESHREBIYA (drinking places), the Arabic term given to the projecting oriel windows in Cairo, enclosed with lattice-work, through which a good view of the street can be obtained by the occupants without being seen; the term was derived from the small semicircular bow, in which porous water-bottles are placed to cool by evaporation in the air.

MESMER, FRIEDRICH (or Franz) ANTON (1733–1815), Austrian doctor, from whose name the word "mesmerism" was coined (see HYPONOTISM), was born at Weil, near the point at which the Rhine leaves the Lake of Constance, on the 23rd of May 1733. He studied medicine at Vienna under the eminent masters of that day, Van Swieten and De Haen, took a degree, and commenced practice. Interested in astrology, he imagined that the stars exerted an influence on beings living on the earth. He identified the supposed force first with electricity, and then with magnetism; and it was but a short step to suppose that stroking diseased bodies with magnets might effect a cure. He published his first work (De planarum inflaue) in 1766. Ten years later, on meeting with J. J. Gassner in Switzerland, he observed that the priest effected cures by manipulation alone. This led Mesmer to discard the magnets, and to suppose that some kind of occult force resided in himself by which he could influence the bodies of his patients; he thought this force permeated the universe, and more especially affected the nervous systems of men. He removed to Paris in 1778, and in a short time the French capital was thrown into a state of great excitement by the marvellous effects of mesmerism. Mesmer soon made many converts; controversies arose; he excited the indignation of the medical faculty of Paris, who stigmatized him as a charlatan; still the people crowded to him. He refused an offer of 20,000 francs from the government for the disclosure of his secret, but it is asserted that he really told all he knew privately to any one for 100 louis. He received private rewards of large sums of money. His consulting apartments were dimly lighted and hung with mirrors; strains of soft music occasionally broke the profound silence; and the patients sat round a kind of vat in which various chemical ingredients were concocted. Holding each other

Hari-rud (river from Herat, which after its junction with the Khashi is called Tejen), 450 m. E. of Teheran (350 by road) and 305 m. by rail W. of Herat, in 36° 15′ N., 59° 36′ E., at an elevation of 3,800 ft. Its population is about 70,000 fixed and 10,000 floating, the latter consisting of pilgrims to the shrine of Imam Reza. 

The town is of irregular shape, about 6 m. in circumference and surrounded by a mud wall with flanks. In the western-central corner of the enclosure stands the citadel (ark), within a wall 25 ft. high and a broad dry ditch which is 40 ft. deep in parts and can be flooded from neighbouring water-courses. The city has five gates, and from one of them, called Bala Khiaaban gate (upper Khiaiban), the main street (Khiaiban), 25 yds. broad, runs in a north-west-south-east direction, forming a fine avenue planted with plane and mulberry trees and with a stream of water running down its middle. The shrine of Imam Reza is the most venerated spot in Persia, and yearly visited by more than 100,000 pilgrims. Eastwick thus describes it (Journal of a Diplomat's Three Years' Residence in Persia, London, 1864):—

The quadrangle of the shrine seemed to be about 150 paces square, and the outer wall of large flagstones and in the centre was a beautiful kiosk or pavilion, covered with gold and raised over the reservoir of water for ablutions. This pavement was built by Nadir Shah. All round the northern, western and southern sides of the quadrangle are eighty 20 ft. high pillars, and, in a row of alcoves similar to that in which I was sitting, and filled with mullas in white turbans and dresses. In each of the sides was a gigantic archway, the wall being raised in a square from above the entrance. The height of the wall must have been of or 100 ft. The alcoves were white, seemingly of stone or plaster; but the archways were covered with blue varnish or blue tiles, with beautiful inscriptions in white and gold. Over the western archway of the tomb of Imam Reza, surrounded by a silver railing with knobs of gold. There was a flight of steps ascending to these doors, and beyond were two smaller doors encrusted with jewels—the rubies were particularly fine. The inner mosque would contain you could not possibly see a passage a covered with two minarets at the sides, likewise gilt all over. On the right of the Imam's tomb is that of Abbas Mirza, grandfather of the reigning Shah. Near him several other princes and chiefs of note are interred. In the golden dome of the mosque, to the contrast with it, was a smaller dome of bright blue. Here begins the mosque of Gahor Shad. The quadrangle is larger than that of Shah Abbas; and at the eastern side is an immense blue dome, of which so much grass was growing, the place being too sacred to be disturbed. In front of the dome rose two lofty minarets covered with blue tiles. In the bowl of the Bala Khiaiban is a kitchen supported by the revenues of the shrine, where 800 persons are fed daily.

The buildings of the shrine together with a space extending to about one hundred yards beyond the gates of the shrine on each side is sanctuary (bast). Within it are many shops and lodgings, and criminals, even murderers, may live there in safety. The only other notable buildings in the place are some colleges (hengin), the oldest being the M. Do-dar, i.e. "college of two doors," built in 1399, of Shah Rukh, and some fine caravanserais, two dating from 1680.

1 Abul Hassan Ali, al Reza, commonly known as Imam Reza, the son of Jafar, caliph of Khaibar and grandson of Ali, was the leader from whom the party of the Shiites (Shiites) had such hopes under the caliphate of Maimun. Gold coins (dinars) of this caliph are extant on which al Reza's name appears with the title of heir-apparent. The Imam died in March 819 in the village Shad, near Tus, some miles north-west of Meshed. To the Shiites he is a martyr, being believed to have been poisoned by Maimun.

2 This refers to Naar-ud-din (d. 1896), grandfather of Shah Mahoommed Ali (1907).

3 Gahru Shad was the wife of Shah Rukh (1404–1447), and was murdered by that monarch's successor Abu Said, August 1, 1457.

Her mosque was built in 1418.
hands, or joined by cords, the patients sat in expectancy, and then Mesmer, clothed in the dress of a magician, glided amongst them, affecting this one by a touch, another by a look, and making "passes" with his hand towards a third. Nervous ladies became hysterical or fainted; some men became convulsed, or were seized with palpitations of the heart or other bodily disturbances. The government appointed a commission of physicians and members of the Academy of Sciences to investigate these phenomena; Franklin and Baille were members of this commission, and drew up an elaborate report admitting many of the facts, but contrasting Mesmer's theory that there was an agent called animal magnetism, and attributing the effects to physiological causes. Mesmer himself was undoubtedly a mystic; and, although the excitement of the time led him to indulge in mumery and sensational effects, he was honest in the belief that the phenomena produced were real, and called for further investigation. For a time, however, animal magnetism fell into disrepute; it became a system of downright jugglery, and Mesmer himself was denounced as a shallow empiric and impostor. He withdrew from Paris, and died at Meersburg in Switzerland on the 5th of March 1815. He left many disciples, the most distinguished of whom was the marquis de Fersen.

MESSAGER (or LE MESAGNERS), NICOLAS (1658-1714), French diplomatist, belonged to a wealthy merchant family. He gave up a commercial career for the law, however, and became advocate before the parlement of Rouen. In 1700 he was sent as deputy of Rouen to the council of commerce which was established in Paris for the extension of French trade. Here he made his mark, and was chosen to go on three missions to Spain, between the years 1704 and 1705, to negotiate financial arrangements. In August 1711 he was sent on a secret mission to London to detach England from the alliance against France, and succeeded in securing the adoption of eight articles which formed the base of the later Treaty of Utrecht. As a reward for his skill he was made one of the three French plenipotentiaries sent to Utrecht in January 1712, and had the honour of signing the treaty the next year. As he had used much of his own large fortune to keep up his state as ambassador, he was granted a pension by the grateful king of France. His portrait by Hyacinthe Rigaud is in the gallery of Versailles.

MESNE (an Anglo-French legal form of the O. Fr. meien, mod. moyen, mean, Med. Lat. medius, in the middle, cf. "mean"), middle or intermediate, an adjective used in several legal phrases. A mesne lord is one who has tenants holding under him, while himself holding of a superior lord. Mesne process was such process as intervened between the beginning and end of a suit (see PROCESS). Mesne profits are profits derived from land whilst in wrongful possession, and may be claimed in damages for trespass either in a separate action or joined with an action for the recovery of the land. The plaintiff must prove that he has re-entered into possession, his title during the period for which he claims, the fact that the defendant has been in possession during that period, and the amount of the mesne profits. The amount recovered as mesne profits need not be limited to the rental value of the land, but may include a sum to cover such items as deterioration or reasonable costs of getting possession, &c.

MESOCEPHALIC, a term applied by anthropologists to those skulls which exhibit a cephalic index intermediate between the dolichocephalic and brachycephalic crania (see CRANIOLOGY). Taking the longer diameter of a skull, i.e. the one from front to back, as 100, mesocephalic skulls are those of which the transverse diameter varies between 75 to 80.

MESODES of Crete, Greek lyric poet, who lived during the 2nd century A.D. He was a freedman of the emperor Hadrian, on whose favourite Antinous he is said to have written a panegyric. Two epigrams by him in the Greek anthology (Anthol. pal. xiv. 63, xvi. 323) and a hymn to Nemesis are extant. The hymn is of special interest as preserving the ancient musical notation written over the text. Two other hymns—to the muse Calliope and to the sun—formerly assigned to Dionysius of Alexandria, have also been attributed to him.

See J. F. Bellermann, Die Hymnen des Dionysius und Mesodes (1840); C. de Jan, Musées scriptores graeci (1899); S. Reimach in Revue des études grecques, ix. (1896); Suidas, s.v.

MESONERO ROMANOS, RAMÓN DE (1803-1882), Spanish prose-writer, was born at Madrid on the 19th of July 1803, and at an early age became interested in the history and topography of his native city. His Manual de Madrid (1831) was published when literature was at a low ebb in Spain; but the author's appreciative studies and the diction and spirit of his writing next year, in a review entitled Cartas españolas, under the pseudonym of "El Curioso parlarante," he began a series of articles on the social life of the capital which were subsequently collected and called Panorama matritense (1835-1836). Mesonero Romanos was elected to the Spanish Academy in 1838 and, though he continued to write, had somewhat outlived his fame when he issued his pleasing autobiography, Memorias de un setentón, natural y vecino de Madrid (1880). He died at Madrid on the 30th of April 1882, shortly after the publication of his Obras completas (8 vols., 4to, 1881).

MESOPOTAMIA (Mesopotamia, sc. χώρα or Ζώρα, from μέσος, middle, ποταμός, river), one of the Greek renderings of the earlier Semitic names for the river-country that stretches eastward from northern maritime Syria. The earliest appearance of a Semitic name of this kind is in the last paragraph of the biography of Alymose of el-Kab, the aged officer of Tethmosis (Thutmose) I. As early therefore as the late 17th century B.C. the name Naharim (N'wr'n') was in use. That the name written heb. by the form Nahrim(a), which would seem therefore to be the pronunciation then prevalent in Phoenicia (Gebel) and Palestine (Jerusalem). About the same time Naharim (N-h-ryn) is given as the northern boundary of Egypt's domain (year 40 of Amenophis III), and over against Kush in the south (Iomb of Khâhmê: Breasted, Anc. Rec. ii. 350).

The origin of the name is suggested by the Euphrates being called "the water of Naharim,"—on the Karnak stele more fully "the water of the Great Bend (phfr.) of Naharim (N-h-ryn)." (Breasted, Ancient Records of the Near East ii. 255), or in the letter C 265, of the obelisk simply "the Great Bend of Naharim" (loc. cit. note d). The precise meaning of phfr. or Pfr. is not certain. When Breasted renders "Great Bend" of the Euphrates he is probably thinking of the great sweep round between Birejik-Zeugma and Rakka-Nıpkechirom. W. M. Müller, on the other hand, rendering Kreislauf, explains it of the Euphrates water system as a whole, thought of as encompassing Naharim. The Sea of the Great Bend would seem to be the sea or the south-east waters of Naharim, just as the Mediterranean, fed by the south-to-north waters of the Nile, is called the Great Circle (see Cercle). For many centuries after Amenophis IV. the name cannot be found; it next occurs in Hebrew Gen. xliv. 21, where the district from which a wife for Isaac is brought is called Aram-Naharaim. The diphthongal pronunciation of the termination aim is probably a much later development. We should therefore think rather of some small region north of, or, more likely, east of the Naharim portion of the Aramaic speaking domain. Probably the author thought primarily of the district of Harrân. Some generations later Aram-Naharim is used of the district including Pèthor, a town on the west bank of the Euphrates (Deut. xxvii. 24).

The threefold n after Nahar in a stele of Persian or Greek time (inscription of Belshazzar) is probably the genitive for "water," a fourth n being accidentally omitted (Breasted, Ancient Records, iii. § 434).

1. Cf. Aram-Damascus, which means, the Damascus portion of the Aramaic speaking domain, which means, the Euphrates portion of the (Israelitive) highlands—EY "Mount Euphrates."

2. Halévy's suggestion that we are to look towards the Hauran, and think of the rivers of Damascus, has not met with favour.

3. Paddan-Aram (Rev. Vers. better Paddan-Aram; Gen. xxv. 20, &c.) has been connected phonetically with Pâsin, west of the Euphrates, and explained by others as a synonym for Harrân.
used for the whole Euphrates-Tigris country. That would provide a useful name for an important geographical unit, but is too misleading. In view of historical and geographical facts there is much to be said for applying the name Mesopotamia to the country drained by the Khabûr, the Belikh, and the part of the Euphrates connected therewith. It would thus include the country lying between Babylonia on the south and the Armenian Taurus highlands on the north, the maritime Syrian district on the west, and Assyria proper on the east. That is practically the sense in which it is treated in this article. We may begin, however, with the definition of Jēzirat by the Arabic geographers, who take it as representing the central part of the Euphrates-Tigris system, the part, namely, lying between the alluvial plains in the south and the mountainous country in the north. Measured on the Euphrates, this would be from the place where the river, having bored its way through the rocks, issues on to the high plain a little above Samšat (Samassata) only 1500 ft. above the sea, to the springs where Hit (Isa-Id), where probably less than 150 ft. above the sea, begins to make its way through the alluvial deposits of the last few millennia. In these 750 m. it has descended less than 1400 ft. Measured on the Tigris Mesopotamia would stretch from somewhere between Jēzirat-ibn-‘Omar and Mûṣûl somewhere below Tekrit.

In the tract defined, physical changes unconnected with civilization have been slight as compared with those in Babylonia; the two great rivers, having cut themselves deep channels, could not shift their courses far.

i. Natural Divisions.—The stretch from Samšat and Jēzirat-ibn-‘Omar to the alluvial plain seems to divide itself naturally into three parallel belts, highland watershed district, undulating plains and the Mesopotamia proper, the last being a barrier that shuts off the east to west course of the Euphrates and Tigris culminates in the rugged volcanic Kāra-Dāgh (6070 ft.) which blocks the gap between the two rivers, continued westwards on the plain, as the main river bed of the modern Khabûr, the modern Khabûr (the modern capital of the country) at a height of 3500 ft. and westwards by the elevated tract that sends down southwards the promontory of J. Tektek (c. 1950 ft.). (2) At the line where this east to west belt appears to begin there are two small streams which run up into the Tigris and the river, for abundant wheat and barley. (3) From the alluvial flats upwards toward these undulating plains is an extensive and natural tract of steppe land almost destitute of rain. Not far above the transition from the barren steppe land the Mesopotamian wall (125 m. between Tigris and Euphrates) begins equidistant with the Sinjûr chain (about 3000 ft., limestone, 50 m. long, 7 m. broad), continued westwards by a marshy break with the volcanic Tell Kûbâb (basalt, about 1300 ft.), and then the ‘Abd al-‘Azîz range (1950 m. broad), veering to its western end as if to meet the Tektek promontory from the north.

ii. Drainage.—The water system is thus determined. West of Tektek rivers into the Belikh, east of Tektek into the Khabûr. All this drainage, collected into two rivers, the Belikh and the Khabûr, is towards the left bank of the Euphrates, for the Mesopotamia watershed seems to be on a line which is less or from the Tigris until, south of the Sinjûr range, its closing line is possible. The Belikh (Belich, Belichus, Belicor), a stream some 30 ft. wide, has its main source some 50 m. north of the ‘Ain Khālil ar-Raşîm, but receives also the waters of the united Jîrak-Kûb (in its upper course formerly the Pâsan, 27 ft. deep from Edessa, and the plain of the earlier Hîrma, 20 ft. in width), which has come 50 m. from Nasîbîn in the north-east, bringing with it the waters of the many streams from the Tûr ‘Abdin highlands; the north Awi, which at certain seasons brings water due south from the desert, and the main stream of the Khabûr, which has come 60 m. from Ras al-‘Ain in the north-west, after flowing 50 m. by way of Wârêshahr from Karja-Dagh in the north. The Tharthârs (Assyrian Tortîr, in Tukhtû-Nîbî’s inscription Tortîr, the Tigris) was introduced as a sacred river, to lose itself in the desert a little above the latitude of Hit. So it was two generations before Ahab (Annales de Tukulti-Ninû, V. Scheil, 1909). The Arabian geographers represent the Tharthârs as connected at its upper end (by a canal?) with the Khabûr system.
character of surface. The tract between the Belihkh and the Euphrates is in its middle section exceedingly fertile, as is indicated in the name Anthemusia, and according to v. Oppenheim (Z. f. P. u. S., p. 80) the same is true of the common buffalo is often kept by the Arabs and the Turkomans on the Euphrates and the Tigris; on the Euphrates is found the

vii. towns. The town that has survived are on the rivers. Such are Samsat (see Samosata), Rakja (Nicephorion) above the mouth of the Belihkh, Der ez-Zor, a town rising on the right bank, and there is (since 1897) a stone bridge, Ana (on an island; see Ana), and several smaller towns, such as Jeziret Ibn Oman, Mous (q.v.), Tekrit, on the Tigris; Edessa (q.v.), (Hammar), on confluents of the Belihkh; Veranshipsh (Tela), Kas al-Ain (Rhaesan- nia), Mardin (half-way up the mountain wall), and Nasibin (Assy. Nasib, Sinieh, Nisibin), on confluents of the Khahr, Sinjar (Singara) on the Tharthar. Villages are more numerous than have been supposed. Von Oppenheim counted in the district west of Edessa and Harran, in a stretch of two days' march, 300 flourishing villages.

viii. political divisions. On the whole the natural lie of the country has been the four main divisions, which have of course varied in detail. We only mention a few of the most outstanding. In the pre-Persian period, besides those referred to elsewhere, we may cite Khazari, (Turb Abdin), Guzana (Gozan of the Eunuch sect), and the two parts of the Persische Golf, one the north-west and the other the south-east. There is a remarkable passage in the early history of the area, which is repeated in the older works, and which has been referred to below (§ 4). At Anza (Dür of Tigris) was founded on the lower Tigris (Plate xxvi, No. 59) with a base-relief and an inscription of the governor of Mesopotamia, Shams, the state referred to below (§ 7 end) as being probably Nabonidus. It was found in 1906 some 15-20 W. of Ekki-Harran, Nasaibin, and was a part of the province of Ekki-Harran, an hour and a half north-east of the ruins of Harran. Many parts of Mesopotamia have probably always harboured wandering tribes. Exactly how far the invading lands beyond reach of the streams of irrigation land has yet to be discovered, but it is clear that Mesopotamia was inhabited by the earlier inhabitants of those long-ago lost in the last 5000 years. It has not yet been proved that Edessa is an ancient city (see Edessa; § 2) but it probably was, its name being derived from the Edessa of the Hellenic period, and which can be seen from it, bears a name which seems to indicate its position as a highway centre. (1) An obvious series of routes followed the course of the river, from Thapsacus (Dibbe) down the Euphrates, from Jeziret Ibn Oman to the city of Harran. The Euphrates was crossed at Birejik (Tel Shaddada on the Carcomish?), or Tel Abmar (unidentifid), or Thapsacus. (2) Probably the modern route from Samosata eastwards beyond the Karaja Dagh to Derbik was also well known. The same is doubtles- less the route from the route from Ora by Kas al-Ain and Nasib, and that by Veranshipsh and Mardin to the Tigris. About other cross-roads, such as those from Harran to Tell Shaddada on the Karaja Dagh, or from Ana by al-Jadid to Mous it is dificult to say. Functionally, Mesopotamia is the domain that lies between Babylon and the related trans-Tigris districts on the one hand, and the west Asian districts of Maritime Syria and Asia Minor on the other. Its position has given it a long, complicated and exciting history. The great rivers, in later times theoretically regarded as its boundaries, have never really been barriers (cf. E. Winckler, Allerziicht. Forschungen, iii. 348), whence the vagueness of the geographical terminology in all times. Its position, along with its character, has prevented it often or long, ever playing a really independent part.

The earliest inhabitants of Mesopotamia in approximately historical times were not yet clear. It is possible that its
connection with the north, and Asia Minor, goes back to a very early date. It may be that some of the early north Babylonian kings, such as Khârî, extended over that other. The earliest Babylonian monarch of whose presence in Mesopotamia there is positive evidence is Lugalzaggisi (before 2500 B.C.), who claims, with the help of En-lil, to have led his countless host victorious to the Mediterranean. His empire, if he founded one, was before long eclipsed, however, by the rising power of the Semites. Excavation in Mesopotamia may in time cast some light on the questions whether the Semites really reached Babylonia by way of Mesopotamia,1 when, and whom they found there, and whether they partly settled there by the way. Whether Sharru-GI, Manishtusu and Remush (often called Uru-mush) really preceded, and to some extent anticipated, “Sargon” i.e. Shargani-sharri, as L. W. King now plausibly argues, is not certain; nor whether the 32 kings who revolted and were conquered by Manishtusu, as we now learn, were by the Mediterranean, as Winckler argued, or by the Persian Gulf, as King holds. That Sargon was or became supreme in Mesopotamia cannot be doubted, since there is contemporary evidence that he controlled Amurru. The third portion of the proceedings of Sargon (Sharru-GI-NA) in Suri leave us in doubt what really happened. As he must have asserted himself in Mesopotamia before he advanced into the maritime district (and perhaps beyond: see Sargon), what is referred to in the Omens and the Chronicle 26,472 may be, as Winckler argued (Or. Lit.-Zeit. 1907, col. 296), an immigration of new elements into Suri—in that case perhaps one of the early representatives of the “Hittite” group. According to the Omens text Sargon seems to have settled colonies in Suri, and suggestions of an anticipation of the later Assyrian policy of transportation have been found by King (op. cit.) under the rulers of this time, and there are evidences of lively intercommunication. Mesopotamia certainly felt the Sumer-Babylonian civilization early. It was from the special type of cuneiform developed there, apparently, that the later Assyrian forms were derived (Winckler, Allorien. Forsch. i. 86 sqq.). What the “east revolt of all lands” ascribed to the later part of Sargon’s reign means is not yet clear; but he or his son quickly suppressed it. Mesopotamia would naturally share in the wide trade relations of the time, probably reaching as far as Egypt. The importance of Harrân was doubtless due not only to its fame as a seat of the Moon-god Sin, honoured also west of the Euphrates, and to its political position, but also to its trade relations. Contemporary records of sales of slaves from Amurru are known.

When the Semitic settlers of the age of Sargon, whom it is now common with some justice to call Akkadians (see Sumer), had become thoroughly merged in the population, there appeared a new immigrant element, the Amurri, whose advance as far as Babylonia is to be traced in the troubled history of the post-Gudean period, out of the confusion of which there ultimately emerged the Khammurabi dynasty. That the Amurri passed through Mesopotamia, and that some remained, seems most probable. The god Dagan had a temple at Tiqrâ (near Ishârâ, a little below Circiumres), the capital of Khana (several kings of which we now know by name), probably taking the place of an earlier deity. At Tiqrâ they had month names of a peculiar type. It is not improbable that the incorporation of this Mesopotamian kingdom with Babylonia was the work of Khammurabi himself.

Not quite so successful eventually was the similar enterprise farther north at Assur or Assur (q.v.) on the east margin of Mesopotamia, although we do not know the immediate outcome of the struggle between Assur and the first Babylonian king, Šumu-abî. Possibly the rulers of Babylon had a free hand in a city that they apparently raised to a dominant position than the Semitic rulers of Assur, who seem to have succeeded to men of the stock which we have hitherto called Mitanni, if we may judge from the names of Ushpia who, according to Shalmanesar I. and Esaratdîn, built the temple, and Kikia who, according to Assur-rem-neshû, built the city wall. The considerable number of such names already found in First Dynasty records seems to show that people of this race were to be found at home as far south as Babylonia. Whether they were really called Shubahû, as Ungnad suggests, we may know later.

When Khammurabi’s fifth successor saw the fall of the Amorite dynasty in consequence of an inroad of “Hittites,” these may have been Mesopotamian Shubari-Mitanni; but they may, as Ungnad suggests, represent rather ancestors of the Hittites of later times. It is difficult in any case not to connect with this catastrophe the carrying away to Khâni of the Marduk statue afterwards recovered by Assur, one of the earlier kings of the Cassite dynasty. Whether Hittites were still resident at Khâni we do not know. The earlier Cassite kings of Babylon still maintained the Amorite claim to the four quarters; but it is improbable that there was much force behind them, although we have a document from Khâni dated under Khashshih. It is just as uncertain how long Assur remained under the Babylonian suzerainty of which there is evidence in the time of Khammurabi, and what the relation of Assur to western Mesopotamia was during the early kings whose names have lately been recovered. All these matters will no doubt be cleared up when more of the many tells of Mesopotamia are excavated. Only two have been touched: ‘Arbân on the Khâhûr, where remains of a palace of uncertain date, among other things an XVIII. dynasty scarab, were found by Layard in 1851, and Tell Khalaî, where the conquerors join, and remains of the palace of a certain Kâpar, son of Hanpan of the “Hittite” affinities but uncertain date, were found by von Oppenheim in 1899. A long inscription of a certain Shamshi-Adad [Samsi-Ilhad], extracts from which are quoted by Delitzsch (Mit. d. Deutsch. Or.-Gesellsch. Nr. 21 p. 50), unfortunately cannot be dated exactly, or with certainty everywhere. Tethmosis III. and Ed. Meyer are right, however, who belong to a time not many generations after Assur recovered the Marduk statue. Shamshi-Adad’s claims extend over the land between the Tigris and the Euphrates, and he says that he erected memorials of himself on the shore of the Great Sea.

The mystery of the Hyksos has not yet been solved; but it is not impossible that they had relations with Mesopotamia. After they had been driven out of Egypt (q.v.), when Aḥmûs, the officer of Tethmosis (Thutmos) I., mentions Naharin (late 17th century), he does not say anything about the inhabitants. He seems to imply, however, that there was more than one state. The first mention of Mitanni, as we saw, is under Tethmosis III., who clearly crossed the Euphrates. It is at least possible that common enmity to Mitanni led to a treaty with Assyria (under Assur-nadin-akhe).4 Victorious expeditions into Naharin are claimed for Amenophis II., Tethmosis IV. and Amenophis III. There is little authentic evidence that the Egyptian expeditions were ever so contemptuous or so unprovoking as to sanction the rule; but Shaushatar must have been a key during the lifetime of Tethmosis III., and from cuneiform sources we know the names of six other Mitanni rulers. As they all bear Arayan names, and in some of their treaties appear Arayan deities (Indra, Varuna, Mithra, &c.), it is clear that Mesopotamia had now a further new element in its population, bearing apparently the name Khâri.5 Many of the dynasts in North Syria and Palestine in the time of Tushratta bear names of the same type. The most natural explanation is that Aryans had made their way into the highlands east of Assyria, and thence had penetrated into Mesopotamia, peacefully or otherwise, and then, like the Turks in the days of the Caliphate, founded dynasties. The language of the Mitanni state, however, was neither Arayan nor-Semitic, and may very well be that of the mysterious “Hittite” hieroglyphic inscriptions (see Hittites). Mitanni was one of the great powers, alongside of Egypt and Babylonia, able to send to Egypt the Ninevite Isthar; and at this time as much as at any previous period.

1 Ungnad, Beitr. z. Assy. VI. v. 13.
3 Winckler has identified the Khâri with the Aryans, to whom he assigns a state in Armenia (Or. Lit.-Zeit., July 1910).
other, we think of common political relations binding the districts east and west of the Euphrates. The king mentioned above (Shaushtar) conquered Asahur (Assur), and Assyria remained subject to Mitanni till near the middle of the 14th century, when, on the death of Tushratta, it overthrew Mitanni with the help of Akhe, a north Mesopotamian state, the allies dividing the territory between them. The Hitite king's interference restored the Mitannite state as a protectorate, but with a smaller territory, probably in the north-west, where it may have survived long.

Assyria was now free, and Ashur-uballit (Assur-yuballit acc. to Sayce) knew how to make use of his opportunities, and, in the words of his great grandson, "broke up the forces of the widespread Shubari" (AKA, p. 7, l. 32 seq.). Knowing what we know of the colonizing power of the Assyrians, we may assume that among the "Mitanni" and other elements in the Mesopotamian population there would now be an increase of people of "Assyrian" origin. On the tangled politics of this period, especially Mesopotamia's relations with the north-west, the Boghaz-Keui documents may be expected to throw a great deal of light. We know already a little more of the chequered history of the Amorites in the Naharin district, best by great powers of three sides. When Bit-Adini of Babylon no doubt adhered to its old claims of Assyria; but the Kassite kings could do little to contest the advance of Assyria, although some rectifications of the boundary between their spheres are reported.

Mitanni's fall, however, had opened the way for others. Hence when Ashur-uballit's grandson, Arik-den-ilu (written Aramaean PU.DI.III.), carried on the work of enforcing Assyria's claim to the heanship of Mitanni, he is described as conquering the warriors (1) of the Akhlane and the Sutti. The references to these people, who practically make their first appearance in the Amarna correspondence, show that they were unsettled bands who took advantage of the loosening of authority to introduce themselves into various parts of the country, in this case Mesopotamia. Gradually settlements were made, the names of many of which are given by the various Assyrian kings who had at one time or another to assert or reassert supremacy over them—such as Chindanu, Laże, Süli, along the South Euphrates boundary of Mesopotamia, and various districts bearing names compounded with Bit = settlement (see p. 318). The claim of Asshur, as the capital, is made at this time in the correspondence of the king of Ashur-uballit (see Edessa), and Bit-Zamani, near the north near Diarbekr. The specific name Aramaean first appears in the annals of Tiglath-pileser L., unless we identify the Arimi of Shalmaneser I. in Tūr 'Abdin with the Aramu; but the name may probably with fitness be applied to a very large number of the communities mentioned from time to time. Their position in Mesopotamia must have been very like that of the Shammar at the present time (see ad fin.). As they gradually adopted settled life in various parts of the country the use of Aramaic spread more and more (see below, § 3 Persians).

Meanwhile Mesopotamia continued to be crossed and recrossed by the endless marches of the Assyrian kings (such as Adad-nirari, Shalmaneser I. and his son), building and rebuilding the Assyrian empire (see BABYLONIA and ASSYRIA), and eventually pushing their conquests towards Asia Minor at the expense of the Hitite domain. If, on the fall of the Kassites, Nebuchadrezzar I. established more direct relations between Mesopotamia and Babylon, his work was presently undone by the vigorous campaigns of Tiglath-pileser I., who seems to have even won Egypt's sanction of his succession to the Hitite claims. The newly recovered (1909) tablet of Tukulti-Ninib, the grandfather of Shalmaneser II., is interesting from its account of an expedition down the course of the Tigris to Hitt = Id (river and town now first mentioned in cuneiform sources) and up the Euphrates to the Khabur district.

Now that Mesopotamia had passed out of the hands of Babylon, all that the later kings could do was to encourage local Mesopotamian rulers in their desire for independence (Nabu-apliuiddin). These were convinced that Assyria was master, but refused their tribute when they thought they dared. To thoroughly overpower the troublesome Bit-Adini (see above, § 3, viii.), which had naturally been aided by the states west of the Euphrates, Shalmaneser II. (860-825) settled Assyrians in their midst. Harran was one of the few places that remained on his side during the great insurrection that darkened his last days. Similarly the province of Guzana (Heb. Gozan, l'αώκαρης), on the Khabur, held with the capital Asshur in the insurrection that occurred in 763 (the year of the eclipse), when evidently some one (An-ad-nirari?) wore the crown, at least for a time. Harran was clearly closely associated with Asshur in the rights and institutions that were the subject of so much party struggle in the new Assyrian empire that began with Tiglath-pileser IV. (see BABYLONIA and ASSYRIA). When the policy of transporting people from one part of the empire to another was developed, new elements were introduced into Mesopotamia, amongst them Israelites, of whom perhaps traces have been found in the neighborhood of Harran at Khanan (4). These new elements have been more organically attached to the Assyrian state as such than the older inhabitants, to whom the affairs of state at Nineveh would be of little interest. On the conditions at Harran some light is thrown by the census partly preserved in Ashurbanipal's library. The governors of several Mesopotamian cities, such as Naṣībīn, Amid, took their turn as eponyms; but this would not have much significance for the people.

Hence even the fall of Nineveh (607 b. c.), apart from what such cities in Mesopotamia as held by its last kings suffered through the invasion, first perhaps of Nabolopassar, who in 609 b. c. claims to be lord of Shubari, and then of the Medes, would be a matter of comparative indifference; tribute paid to Babylon was just as hard to find as if it were going to Nineveh. Necho did not succeed, like his great XVIIIth dynasty predecessor, in crossing the Euphrates. He was defeated by Nebuchadrezzar at Carchemish (605 b. c.), and Mesopotamia was confirmed to Babylon. Its troubles began again shortly after Nebuchadrezzar's death; the Medes seized Mesopotamia and besieged Harran. Both officials would naturally have been eager to assert their rights and cleared Mesopotamia, and Nebonidas (Nabu-naid) was able, drawing on the resources of the whole of Syria for the purpose, to restore the famous temple of Sin at Harran, where a few years later he erected in memory of his mother, who seems to have been a priestess there, the stele published in 1907 by Pogon.

The fragmentary nature of the records does not enable us to follow the steps by which Cyrus became master of Mesopotamia, in which he probably met with little or no resistance. How much of Mesopotamia was involved in the revolt of what the Persian inscription calls Assyria (Ašhur) is not clear. Nor does it appear with certainty to which of the twenty satrapies into which, according to Herodotus, the Persian empire was divided, Mesopotamia belonged; probably it was included in 'Abar nahārā. The fact is, we have no information from native sources. The probability is that conditions remained very much what they had been; except that the policy of transportation was not continued. The satrapies and other spheres of interest became the seat of Persian extraction; but local affairs were probably managed in the old way, and there was no important shift of population. The large Aramaic infusion had by this time been merged in the general body of the people. These settlers doubtless influenced the "Assyrian" language; but gradually, especially in the west, their own language more

2 On a wrongly supposed much earlier occurrence of the name Achlamu, see Klio, vi. 193 n. 3.

MESOPOTAMIA

and more prevailed. Although Aramaic inscriptions of the Assyrian period, like those of Zanjili or that of King ZK Rahbash, have not been found in Mesopotamia, already in the time of Shalmaneser II, mention is made of an Aramaean letter (Harper, *Ass. Bab. Letters*, No. 872, obv. i, 10), and Aramaic notes on cuneiform documents begin to appear. Weights with Aramaic inscriptions (the oldest from the reign of Shalmaneser IV., 727–22) were found at Calah. By the Achaemenian period Aramaic had become the international language, and was adopted officially.

How Mesopotamia was affected by the passing of Persian armies on their way to suppress revolts in Syria or Egypt, or to conquer Greece, we do not know; on the whole it probably enjoyed unpunctuated peace. The expedition of Cyrus the Younger, with which Xenophon has made us so familiar, only skirted the left bank of the Euphrates. The route followed by Alexander, though he also crossed at Thapsacus, took him unresolved across the northern parts; but the poor people of Mesopotamia suffered from the measures taken by their satrap Mæazaes to impede Alexander's progress. In spite of this, where Cyrus failed Alexander succeeded.

What would have happened had Alexander lived we can only guess. Under the Seleucids Babylon was moved across the plain to Seleucia; but before long the central authority was transferred to the other side of the Euphrates, to Antioch or elsewhere—a fateful move. It is improbable that cuneiform and the Babylonian language continued to be used in Mesopotamia during the Hellenistic period, as it did in Babylonia, where it was certainly written as late as the last century B.C., and may have been a learned language till the second Christian century. Unfortunately there are no native documents from the pre-Christian Hellenistic period. That the Hellenizing process went as far as it did in Syria is unlikely; and even there Aramaic remained the language of the people, even in the towns (cf. Edessa). Still, Greek influence was considerable. This would be mainly in the towns, the growth of which was quite a feature of the Macedonian rule in Mesopotamia (Pliny, *H.N.*, 30, § 117). This is seen in the Greek names which now appear: such as Seleucia opposite Samosata, Apamea (= Birejik) opposite Zegma, Hierapolis (= Membij), Europos, Nicatoris, Amphipolis (= Thapsacus, or near it), Nicephorium (er-Rakkâ), Zenodotus (stormed by Crassus), all on or by the Euphrates; Edessa (E.D.) on the upper waters of the Belikh, Ichna (perhaps Kinsî, above the junction of the Qaramush with the Belikh). These are all in the Osroene district; but Nisibis became an Antioch, and as its district was known as Mesopotamia, Nisibis doubtless was more Greek settlements. To a less extent the same influences would be at work in towns called even by Western writers by their real names, such as Batnae, Carrhae (Charran), Rhesaina.

Mesopotamia naturally had its share of suffering in the struggles that disturbed the time, when Eumeons or Seleucids traversed it or wintered there. It was invaded and temporarily annexed in 245 by Ptolemy III. Euergetes in his rapid expedition beyond the Tigris. When Molon revolted on the accession of the youthful Antiochus III. (224 B.C.) he entered Mesopotamia from the south. Antiochus skirted the northern highlands by way of Nasibin. How far the natives of Mesopotamia shared the desire of the Greek settlers (Joseph, *Antiq.* xiii. 5, 11, § 184–186) to help Demetrius II. Nicator in checking the aggressions of the rising power of Parthia under Mithradates I. we do not know. It was in Mesopotamia that a large part of the army of Antiochus VII. Sidetes was destroyed in 130 B.C., and the Syrian kings did not again seriously attempt to assert their rule beyond the Euphrates. When Phraates II. turned the Scythians against himself, however, even Mesopotamia suffered from the plunderers (John, *Antioch*, in Müller iv. 561). The immigration of Arabs in the latest cuneiform document of certain date is a contract of 68 B.C. (cf. *Ktio*, vi. 223 n. 3).

It must have been going on for long. About this time they even founded a dynasty in Aramaean Osroene (see Edessa).

Under the successes of II. Mithradates Mesopotamia was a definite part of the Parthian empire, of which the Euphrates became the western boundary; but in 92 B.C. on that river his ambassador met Sulla, though the long duel did not begin immediately.

It was perhaps a Parthian governor of Mesopotamia that was called in to help Strato of Beroea against Demetrius III.; but before long Mesopotamia (especially the district of Nisibis) was attached to the growing dominions of Armenia under its ambitious king Tigranes, perhaps through alliances with the Parthians. The lost territory, however, was recovered by Phraates III., and Mesopotamia was guaranteed to Parthia by the treaties of Lucullus and Pompey (66 B.C.). It was traversed, however, several times by the Parthians when their empire was in process of formation; the declaration of war against Armenia involved it with Rome. Gabinius crossed the Euphrates (54); but the command was assumed by Crassus, who, though he seized Ichna, &c., and Raqqa (Rakka), fell at Carrhae (53), and the Parthian domination was confirmed. The tragedy of the I. of March saved Mesopotamia and the East from a great campaign by Julius Caesar, and it was at the hands of Ventidius Basso, and west of the Euphrates, at Gindarus (north east of Antioch), that the Parthians received the check that put an end to Roman penetration and with which Mesopotamia, beyond the Euphrates, was left to the Parthians, and that there he saw his army melt away. The affairs of Armenia continued to be the source of friction between Parthia and Rome, and Nisibis changed hands several times. The expedition against Rome, in A.D. 36, Tiridates found support in his attempt to secure the Parthian dominion in the north-west; and, on the other hand, his troops were even twice within the coasts of Nisibis, and in 66 a peaceable arrangement was come to. Of the half-century that preceded Trajan's great oriental undertaking not much is known. When in 115 Trajan entered Parthia he could find no Roman troops, as far as Nisibis, and when he crossed the Tigris, it became a province as far as Singara. The woods at Nisibis, the headquarters, provided material for the boats with which in 116 he crossed the Tigris. Hatra, an interesting fortress which seems to have been Aramaean, fell, and the army advanced to Hit, where it found the fleet that was subsequently transferred to the Tigris. For the revolt that occurred while Trajan was on the Persian Gulf, in which the Jews had an important hand, Nisibis and Edessa suffered capture and destruction. Hatra successfully resisted, however, and Hadrian abandoned Mesopotamia, setting the boundary at the Euphrates. Again for half a century there is not much to relate. Then, when Vologases, yielding to his growing discontent, took advantage of the death of Antoninus Pius to try his hand at the Euphrates, the Popes, after the recent storming of places such as Nicephorium, Edessa, Nisibis, western Mesopotamia was once more Roman as far as the Khâbild, Carrhae becoming a free city and Osroene a dependency.

By this time Christianity had secured a foothold, perhaps first among the Jews (see Edessa), and we enter upon the earliest period from which documents in the Edessan dialect of Aramaic, known as Syriac, have been preserved. Unfortunately they contain practically nothing that is not of Christian origin. On the death of Aurelius Hatra aided Nijb against Septimius Severus in 204; Osroene rose against Rome, and Nisibis was besieged and other Roman places taken; but Septimius Severus, who had been before the Euphrates, on his return turned the Parthians and recovered the whole country, of which he made Nisibis metropolis, raising it to the rank of a colony, the Sinjâr district, where Arabs from Yemen had settled, being incorporated. On his retiring everything was undone, only Nisibis holding out; but on his reappearance in 198 the Parthians withdrew. Again the Euphrates bore a Roman fleet. Hatra, however, was besieged twice in vain. Peace then prevailed till Carcalla's unpaved attack on Parthia in 216, after he had reduced Osroene to a province. On his assassination near Carrhae (217), Macrinus was defeated at Nisibis and had to purchase peace, though he retained Roman Mesopotamia, reinstating the princiely house in Osroene.

The power of Adashir, the Sassanian, however, was already rising, and the Parthian Artabanus died in battle in 224 (or 227), and Ardashir proposed to prove himself the successor of the Achaemenidae. Hatra resisted the first Persian attack as it...
had resisted Rome; but Mesopotamia was overrun, Nisibis and Carrhae being taken (253). It was immediately, indeed, recovered by Alexander Severus, and retained, whatever was the precise success of the war; but Nisibis and Carrhae were retaken by the Persians in the reign of Maximin. Under Gordian III. in 244 Mesopotamia was entered by a great Roman army which recovered Carrhae, but lost Nisibis and defeated the Persians at Rhesaena; but when Gordian, after a difficult march down the Khûbûr, was murdered at Zatalja below Ctesiphon, Philip the Arab (244) made the best terms he could with Shapur I. Whatever they were, the Roman garrisons seem not to have been really withdrawn. A rest for Mesopotamia seems to have followed; but in 258 Shapur, tempted by the troubles in the Roman empire, overran the country taking Nisibis and Carrhae, and investing Edessa, and when Valerian invaded Mesopotamia he was eventually made prisoner, by Edessa (260).

After Shapur's cruel victories in Syria, however, he was defeated by Odaenathus, who relieved Edessa, and Mesopotamia became for ten years practically part of an Arabien Empire (see PALMYRA), as it was to be four centuries later. In consequence of the revolt of Zenobia Mesopotamia was lost to Rome, and the Euphrates became the frontier. Aurelian overthrew the Palmyran rule; but he was assassinated before he could carry out his intended expedition against Persia, Probus was assassinated before he was able to do anything (or much), and although Carus easily overran Mesopotamia, which became Roman again, and even took Ctesiphon, the Romans retreated on his death (283–4). The next incident is the defeat of Galerius, between Carrhae and Callinicus, where he had entered Mesopotamia (about 296), in the war provoked by Nares in consequence of his relations with Armenia. When it was retrieved by a signal victory, Diocletian advanced to Nisibis and thence dictated terms of peace by which Mesopotamia to the Tigris was definitely ceded to Rome (298).

One result of the connexion with Rome was, naturally, that Mesopotamia came within the range of the Decian, and later the Diocletian persecutions (see Edessa: § Sassanian Period). At the Nicene Council in Armenia, and from Nisibis (Jacob of Rhaeaen, Macedonopolis (on the Euphrates, west of Edessa), and Persia (Harnack, Mission and Expansion of Christianity, ii. 146; see generally 142–52).

After a forty years' peace the struggle was resumed by Shapur II. Nisibis thrice endured unsuccessful siege (338, 346, 350), although meanwhile Constantine had suffered defeat at Singara (348). Then Mesopotamia enjoyed two short rests (separated by a sharp struggle) while the rivals were engaged elsewhere, when in 363 Julian (q.v.) made his disastrous attempt, and Jovian bought peace at the price, among other things, of Singara and Nisibis—i.e. practically all eastern Mesopotamia.

The surrender of Nisibis, which had been in the possession of Rome for so many generations, caused consternation among the Christians, and Epheam (q.v.) moved to Edessa, where his "school of the Persians" soon became famous (see Edessa). In the war of 421, in which the north-east of Mesopotamia was chiefly concerned, the Romans failed to take Nisibis, and it became a natural rallying point for the Nestorians after the decision of Ephesus (431). Matters were still more complicated when the Western Christians of Edessa found themselves unable to accept the ruling of Chalcedon against Monophysitism in 451 (see MONOPHYSITES), and there came to be three parties: Nestorians (q.v.), Jacobites (see JACOBITE CHURCH) and Melchites (q.v.).

In the beginning of the 6th century there was another severe struggle in Mesopotamia, which found an anonymous Syriac historian (see Edessa), and in infringement of agreement the Romans strongly fortified Dâarb against Nisibis. The Persian invasion of Syria under Kavadh I. (q.v.) was driven back by Belisarius; but the latter was defeated in his pursuit at Rakka (531). The peace begun by Chosroes I. (532) was not long kept, and Roman Mesopotamia, except the pagan Harrân, suffered severely (540), Edessa undertaking a trying siege (544). The fifty years' peace also (542) was short-lived, the Romans again failing in an attempt to recover Nisibis (573), whilst Chosroes' siege of Dâarb was successful. Mesopotamia naturally suffered during the time of confusion that preceded and followed the accession of Chosroes II., and the Romans recovered their old frontier (591).

With the accession of Phocas (602) began the great war which shook the two kingdoms. The loss of Edessa, where Nares revolted, was temporary; but the Roman fortress of Harrân fell after nine months' siege (c. 605); Harrân, Râs al-'Ain and Edessa followed in 607, many of the Christian inhabitants being transported to the Far East, and Chosroes carried the victorious arms of Persia far into the Roman Empire. Finally Heraclius turned the tide, and Kavadh II. restored the conquests of his predecessor. The Syrian Christians, however, found that they had only exchanged the domination of a Zoroastrian monarch for an unsympathetic ecclesiastical despotism. In the confusion that followed, when men of letters had to live and work in exile, Nisibis set up for a time (631–632) a grandson of Chosroes II. Finally all agreed on Yazdegird III.; but, while Chosroes II. and Heraclius had been at death grips with each other, a great invasion had been preparing in Arabia.

The Arab tribes in Mesopotamia were Christian, and Heraclius at Edessa hoped for their support; but Karâşiyâ and Hit succumbed (636), and then Tekrit; and Heraclius retired to Samosâta. When in 638 he made another attempt, it is said at the entreaty of the Mesopotamian Christians, Arab forces appeared before Rakka, Edessa, Nasûbin, and other places, and all Mesopotamia was soon in the hands of the Arabs. Henceforth it looked to Damascus and to Kûfâ and Baṣra, instead of to Constantinople or Ctesiphon. The new régime brought welcome relief to the Christian part of the population, for the Arabs took no note of their orthodoxies or heterodoxies. (Moawiya is said to have rebuilt the dome of the great church at Edessa after an earthquake in 678.) Fortunately for Mesopotamia the seats of the factions which immediately broke the peace of Islam were elsewhere; but it could not escape the fate of its geographical position.

The men of Rakka were compelled to help 'Ali, after his march into Mesopotamia from near Palmyra, in getting a bridge made at Rakka to convey him to Sitif. Not long afterwards there was a new excitement in Moawiya's incursion across the Tigris. The discontent under Yazid III. was keen in Mesopotamia, where Merwan, in fact got a footing, and when the troubles increased after he became caliph he abandoned Damascus in favour of his seat at Harrân. His son was besieged by Dâbâbâk and his Khârijîtes and Saâfardis in Naṣîḇân; but a fierce battle at Mârûn ended in Merwan's favour (745). The cruelties that accompanied the overturning of the Merwan dynasty, the ravages of the Moslems on the coast towards Mesopotamia, and Harrân had to undergo a siege by one of Merwan's generals. It was next besieged by al-Mansûr's brother; but the battle between the brothers was fought at Naṣîḇân. It was decisive, but there were further risings, involving Mesopotamia.

An inevitable effect of the reign of al-Mansûr had been that the kindred language of the Arabs gradually killed the vernacular Syriac of Mesopotamia (see Edessa) as the alien Greek and Persian had shown no tendency to do, and the classical period (4th to 8th centuries) of the only Mesopotamian literature we know, such as it is, useful but uninviting, came to an end (see SYRIAC LITERATURE). This naturally encouraged grammatical study. Among the Arabic-speaking people the revolution which displaced the Arabic court of Damascus in favour of a cosmopolitan world centred at the Babylonian seat of the civilizations dealt with in the preceding paragraphs naturally gave an impulse to the wider scholarship. Translations were made from Greek, as, e.g. by Thâbit b. Qurra of Harrân (d. 907), and from Pahlavi.

Mašûr built a castle at Rakka opposite Rakka to control the country round, and his son Harrân al-Rashîf actually resided during most of his reign at Harrân itself, while his brothers, who were two generations later al-Battâni of Harrân was making the astronomical observations on which his tables were based (see ALBATEGNIUS) Abu Qurra, bishop of Harrân, and acquaintance of the caliph Ma'mûn, who was one of the earlier Arabic Christians, has been thought to have contributed to the influences...
that developed the Mutānīli (Mutaila) sect. Nasībin was the scene of another revolt (793) under a Khārijite leader. Hārūn’s son Motasem displeased the people by creating a bodyguard of Turks, and therefore transferred his seat to Sāmarrā. This put the caliph at the mercy of their guards.

Maridin was under the suzerainty of Ahmad ibn Tūbān of Egypt and his son; but before the end of the 9th century the Ḥamādīnī, descendants of the Arab tribe of Ṭāghlib, were in possession of Mardin, and in 919 one of them called his troops together and declared for the Fatimids. Later the fitna of the Nāṣir ad-Daula and Saif ad-Daula ruled over Mesopotamia and North Syria respectively. Meanwhile the caliph Muhādīr appointed to this kingdom was seen to be a fugitive at Mūsālūn, Nasībin, Ra’ba (944). The Ḥamādīnī were driven from their places, such as Mūsālūn, Nasībin, Ra’ba, Ḥarrūn, between 956 and 996. By 1055 the Seljuqs had taken the caliph under their charge. They arrived at Jerusalem in 1076, the first crusaders reached Asia in 1099, and less than 40 years later there was no longer any hope of the Seljuk’s quickly disintegrating. The son of a slave of the third Seljuk sultan, Zangi, governor of ‘Irāq, made himself gradually (Mūsālūn, Sinjār, Jezīra, Ḥarrūn) master of Mesopotamia from 1195 to 1244. Mūsālūn was one of his sons, Saif ad-Dīn, and branches sprung up at Sinjār and Jezīra.

To the same period belong other Ayyubite dynasties, Begītīs at Ḥarrān, Tekrit, &c.; Ortokids at Edessa, Ava, &c., with Mardin as their headquarters. By 1185-1186 Saladin had made his grand tour of Asia, and checked the Persian and Arab pressures, and what the XVIIIth and XIXth Egyptian dynasties had attempted in vain. Mesopotamia remained in the hands of the Ayyūbi family till the appearance of the Mongols. The petty principalities were unable to withstand the pressure of the Mongol conquerors. Near Bīrā was the scene of one of their victories (1273), and their authority was extended to Karkishiyā. The Ortokī tradition survived the Mongol inundation, and it was in the 14th century that its laureate Saifī ad-Dīn flourished. From the Mongol invasion, the 13th century western Asia has never recovered. Then, before the next century was out, came the invasion of Timur (1393-94). The Ortokīs were followed by the Karkakūnīs, in 1502 Mesopotamia was under the suzerainty of Baybars, son of the Mamlūk Khalil; but in 1516 it came under the Ottoman Turks, to whom it has belonged ever since. The inroad of the Persians in the 17th century was confined to the south.

Since Mesopotamia finally came into the power of the Ottoman sultans considerable changes in the population have occurred. About that time parts of a confederation of tribes which had taken the name of Shamar from a mountain in their neighbourhood, moved northwards from Central Asia, and were better fitted for success. Displacing their forerunners, they made themselves masters of the Syrian steppe—until their possession was in turn disputed by a later emigrant from Arabia, for whom they finally made room by moving on into Mesopotamia, over which they spread, driving before them their predecessors the Tāl (whose name the Mesopotamian Arabesquers had adopted as a designation for Arab in general), partly north of the Sinjār, partly over the Tigris. Others they forced to abandon the nomadic life, and settle by the Khaibūr (e. g. the Jebur) or the Euphrates. These adjustments, it is supposed, had been effected by 1700.

In 1831 ‘Ali, a newly appointed Turkish governor of Bagdad, induced Sūfīg, the chief of the Jerbā, the more important division of the Shammar, to help him to dislodge his predecessor, Dīūd, who had once helped him, but then refused him the promised payment. To defend himself from the enraged Shammar, ‘Ali summoned the Anāzā from across the Euphrates. Having also succeeded in detaching part of the Shammar under Shīloh, he told the ‘Anāzā he no longer needed their help. In the futile attempt of the three parties to dislodge the ‘Anāzā ‘Shīloh lost his life; but with the help of the Zuḥbīd the other two succeeded, and Sūfīg was now supreme "King of the Steppe," levying blackmail as he chose from the tribes. At length ‘Ali, who meditated to seize the Porte made his nephew a rival sultan; but he hastily assassinated him. Sūfīg then suffered the same fate himself at the hands of the pasha, but has since become a hero. Two of his sons became more important than the government in consequence, while for years all Mesopotamia was in danger, till the pasha was put to death in 1868, and Fārābī, the eldest son, a peaceable man who had been made pasha, became supreme. One of Sūfīg’s widows had fled to her Tāl kindred in Central Arabia with her youngest son Fārābī; when he grew up she brought him back in the seventh century, and he immediately attracted a great following. He kept to the far north of Mesopotamia to avoid his brother Fārābī; but finally half-sedentary tribes on the Khābūr and the Belīkh became tributary to him, and a more或 less warlike warfare sprang up between the tribes, which ended in a partition of Mesopotamia.

Ferhān and the South Shammar claimed the steppe south-east of a line from Mūsālūn to Mayādīn (just below Karkishiyā), and Fārābī and the North Shammar the north-west. Since Ferhān’s death the Porte has favoured one after another of his many sons, hoping to keep the South Shammar disunited, especially as they are more than the others. The Shammar have been in undisputed mastery in the neighbourhood of Bagdad, practically all tribes paying khums to them, and even the towns, till the government Garrisoned them. Some 60 of these (the important) tribal chiefdoms, of which there are two thousand tents (or houses) each, representing a population of several hundred thousands are described by Oppenheim. Each has its recognized camping ground, usually one for summer and another for winter. Most of them are Arab and Mahomedan. Some are Christian and some are not Arab: viz. Kurds, Turkomans or Circassians. For some years the Porte has been applying steady pressure on the nomads to induce them to settle, by increasing the number of military posts, by introducing Circassian colonists, as at Ras al-Ain, sometimes by forcible settlement. More land is thus being brought under cultivation, the disturbing elements being slowly brought under control, and life and property are becoming more secure.

Security is what the country chiefly needs. Hence its primary interest in the railway scheme, with a view to agricultural development and perhaps the growth of cotton; Sir W. Willcocks' irrigation schemes had not up to 1910 affected Mesopotamia directly. Despite the realization that the railway scheme was inadequate to effect the improvements demanded. The new regime introduced in 1908 seems to justify a hopeful attitude. Apart from the disturbing effects of recent events in Persia, an exposition of present conditions would show progress. Exact statistics are not available because the vilayet of Mūsālūn (35,130 sq. m., 351,200 pop.) takes in on the east territory with which we are not concerned, and omits the Osroene district, which goes with Aleppo. Urfa is a town of 55,000; Mūsālūn, 61,000, Bagdad, 145,000. The exports of Mūsālūn for 1908 (in thousands of pounds sterling): United Kingdom 315, India 43, other countries 52, parts of Turkey 218; the imports: United Kingdom 36, India 16, other countries 35, parts of Turkey 24. The language is in most parts Arabic; but Turkish is spoken in Birejik and Urfa, Kurdish and Armenian south of Dīarbār, and some Syrian in Tūr 'Abīdīn. There are Christian mission institutions of European origin in various places, such as Urfa, Mūsālūn, Mūsālūn. An interesting survival of early faiths is to be found in the Yazidis of the Sinjār district.

Authorities—Land and People: full references to Greek, Latin, Arabic, and other writers are given in Rittner’s Annalen, 645, 650-652; for the conditions since the Arab conquest, Gye le Strange, Lands of the Eastern Caliphate (1905), chiefly pp. 86-114, is especially useful. Of recent works the following are valuable: E. Oppenheim, From Anu to Ziggur, vol. ii (1883); M. v. Oppenheim, Von Mittelmeer zum Persischen Golf, vol. ii (1889). We may mention further D. G. Hogarth, The Nearest East (1902); E. Perrot, History of Art, v. vi. (1909); K. Regling, Zur historischen Geographie des mesopotamischen Flusses (Crawshay’s, his partial translation), in Klio, 1, 433-476; M. Sykes, “Journeys in North Mesopotamia” in Geogr. Journ., xxx. 237-254, 384-395; “The Western Bend of the Euphrates,” op. cit. xxxiv. 61-65 (plans of two castles); D. Fraser, Short Cut to India (1906); W. Kurz, "Beurteilung der Aussichten auf eine Wiederbelebung der Kultur der Euphrat- und Tigrisniederung," in Deutsche geographische Blätter, xxxi. 147-179 (1908); E. Peters, The Bagdad Railway in Contemp. Rev., 1908, 570-591; K. Barth, Die Morgenlandforschung, S. (1910); S. Sykes, “Oppenheim,” op. cit., xxxv. 396-412. The annual Consular Reports most nearly bearing on Mesopotamia are those for Aleppo, Mūsālūn, Bagdad and Basra.

Maps.—The following deserve special mention: v. Oppenheim, op. cit., a most valuable large-scale folding map in pockets of volumes; S. Sykes, Geogr. Journ., xxx. op. p. 355, and xxxiv. opp. p. 120; Hogarth, op. cit., orientalische, &c.

Present Time.
**MESOXAIC ACID—MESOZOAA**

The central cell is formed by the layer of the first two blastomeres, and remains quiescent until surrounded by the micromeres or products of division of the smaller blastomere. It then divides unequally, and of the two cells thus formed the larger repeats the process. Each of the two small cells are now called primary germ cells, and they enter into and lie inside the large central cell. The primary germ cells divide until there are eight of them all lying within the axial cell. At this stage the future of the parasite may take one of two directions. Following one path, the animal (now called a “Rhombogen”) gives rise by the segmentation of its primary germ cells to vermiciform larvae which, though smaller, are but replicas of the parent form. Following the other path, the animal (now termed a “Mesozoa”) gives rise by the segmentation of its primary germ cells to vermiciform larvae which, though smaller, are but replicas of the parent form. Following the other path, the animal (now termed a “Mesozoa”) gives rise by the segmentation of its primary germ cells to vermiciform larvae which, though smaller, are but replicas of the parent form. Following the other path, the animal (now termed a “Mesozoa”) gives rise by the segmentation of its primary germ cells to vermiciform larvae which, though smaller, are but replicas of the parent form.

Berlin (1906); “Völlige Nachrichten über die Ausgrabungen in Baghaz-koi im Sommer, 1907,” in Mitteilungen der Deutsch. Orient. Gesellschaft, No. 35, and “Sari” in Oriental. Lit.-Ztg., x. 281-299, 345-357, 401-4, 643; O. Weber; the notes to Knauff’s, Hethits’s Armarna Tafeln; A. Ungnad, Untersuchungen zu den . . . Urkunden aus Dibaj (1906), pp. 8-21; P. Schnabel, Studien zur bab.-assyrischen Chronologie (1908); A. Sanda, Die Aramäer (1902) in Der Allt Orient: Ausgrabungen, M. Strock, “Uber die älteste deutsche Schreibweise der Aramäer,” in Klio, vi. 185-225. For the later periods see Perrot and Chipiez, Hellenism; Rome: History; Partia; Syriac Literature; Caliphate and authorities there given.

**MESOXAIC ACID** (dioxymalic acid), (HOC)₂CO(OH), or C₅H₅O₆, is obtained by hydrolysis of alloxan with baryta water (J. v. Liebig, Ann., 1838, 26, p. 298), by warming acinaric acid with lead acetate solution (F. Fischer, Ann., 1882, 215, p. 283), and from glyceric diacetate and concentrated nitric acid in the cold (E. Seelig, Ber., 1891, 24, p. 347). It crystallizes in delicate

2. Flattened form of female.
3. Cylindrical female.

which then give rise to males again, whereas the females which produce the vermiciform embryos arise from unfertilized vermiciform larvae. After the infusoriniform larvae have left the parent’s body, the Rhombogen takes to producing vermiciform offspring, and this becomes a secondary Mesozoa. Thus, if the above views be correct, a Rhombogen is a protandrous hermaphrodite.

E. Neresheimer has recently described under the name of *Lohangenna colenata* an organism parasitic in *Prillitaria* which shows marked affinities with the Rhombogen. The genus *Hoplodoscia* of which two species have been found in the worms *Travicia* and *Clymene* by Dogiel is classed as a new group of Mesozoa.

Class II. ORTHONECTIDA (A. Giard.)—The Orthonectida contain animals with a central mass of eggs destined to form male and female reproductive cells surrounded by a single layer of ciliated ectodermal cells arranged in regular rings which contain varying numbers of rows of cells. Muscular fibres occur between the outer and inner cells. The sexes are separate and unlike, and there are two kinds of females, cylindrical and flat. There are but two genera, *Rhopalaria* and *Staechiorthum*, the latter found in a Polychaete. The male *R. giardi* lives in the body-cavity of *Amphipura squama*, has six rows of ectodermal cells all ciliated except the second, whose cells contain refringent granules. The ectoderm encloses the testis, a mass of cells which have arisen from a single axial cell in the embryo. The female differs from the male in appearance, and in size it is larger. It occurs in two forms: (1) The cylindrical with 8 (or 9) rows of ectodermal cells; here as in the male the second ring is devoid of cilia. (2) The flat females are broader, uniformly ciliated, and have not rings of ectodermal cells. The central mass of cells forms
Ova which are free in the cylindrical forms; they leave the mother through the dehiscing of the cells of the non-ciliated ring, are fertilized and develop parthenogenetically into females both flat and cylindrical.

_R. pseudoni_ and _S. giardi_ are said to be hermaphroditic. The parameres take the appearance in a host in the form of a plasmodium comparable with the sporocyst of a Tantamotha. By the segregation of nuclei and some of the surrounding protoplasm, germ cells arise which develop into ciliated larvae and ultimately into females and males. Finally, in some cases, discharge their spermatogonia and ova when they reach sea-water. The product of the consequent fertilization is unknown; presumably it infects new hosts, entering them in the form of a nucleated plasmodium.

The original idea in the Rhizopods and Orthonectida we had animals intermediate between the Protozoa and Metazoa is no longer widely held. The modern view is that the simplicity of their structure is secondary and not primary, and is correlated with the detritus habit of life, which probably derived from some Playthelminthine ancestor and perhaps come nearer to the Tantamotha than to any other group.

**MESSIZOIC ERA—MESSAGER**

In the Mesozoic, geology, the name given to the period of time between the Palaeozoic and Cainozoic eras; it is synonymous with the older and less satisfactory term "Secondary" as applied to the major divisions of geologic time and with the "Flözgebirge" of the Wernerian school. This era is subdivided into a lower, Triassic, a middle, Jurassic, and an upper, Cretaceous period or epoch. The duration of the Mesozoic era was not more than one fourth of that of the Palaeozoic era, measured by the thickness of strata formed during these periods. It was an era marked by peaceful conditions in the earth's crust and by a general freedom from volcanic activity. The sediments as a whole are characterized by the prevalence of limestones as compared with those of the preceding era; they are seldom much altered or disturbed except in the younger mountain regions. Mammals, represented by small marsupials, and primitive forms of birds and bony fishes make their first appearance in the lower strata of Mesozoic age. Saurian reptiles played an extremely prominent part: ammonites and belemnites lived in extraordinary variety in the seas along with the echinoids and pelecypods, which had a great extent supplanted the crinoids and brachiopods of the preceding periods. The first clear indications of monocotyledonous and dicotyledonous angiosperms made their appearance, while Cycads and Conifers constituted the bulk of the land flora.

**MESQUITE, OR HONEY LOCUST,** in botany, a tree, native of the southern United States and extending southwards through Mexico and the Andean region to Chile and the Argentine Republic. It is known botanically as _Prospis juliflora_, and belongs to the natural order Leguminosae (suborder Mimosae). It reaches 40 or 50 ft. in height with a trunk usually not more than 6 to 8 in. in diameter, and divided a short distance above the ground into numerous linear or crooked branches forming a loose sprawling head. The remarkable development of its main root in relation to water-supply renders it most valuable as a dry-country plant; the root descends to a great depth in search of water, and does not branch or decrease much in diameter till this is reached. It can thus flourish where no other woody plant can exist, and its presence and condition afford almost certain indications of the depth of the water-level.

When the plant attains the size of a tree, water-will be found within 40 or 50 ft. of the surface; when it grows as a bush, between 50 or 60 ft.; while, when the roots have to descend below 60 ft., the stems are only 2 or 3 ft. high. These woody roots supply valuable fuel in regions where no wood of fuel value is produced above ground. The leaves are compound, the main axis bearing two or sometimes four secondary axes on which are borne a number of pairs of narrow bluish leaflets. The minute greenish-white fragrant flowers are densely crowded on slender cylindrical spikes from 1½ to 4 in. long; the long narrow pods are constricted between the seeds, of which they contain from ten to thirty surrounded by a thick spongy layer of sweet pulp. The wood is heavy, hard and close-grained, but very strong; it is almost indestructible in contact with soil, and is largely used for posts and railway ties. The ripe pods supply the Mexicans and Indians with a nutritious food; and a gum resembling gum arabic exudes from the stem.

An allied species _Prospis subgusca_, a small tree or tall shrub, native of the arid regions of the south-western United States, is known as the screw-bean or screw-pod mesquite from the fact that the pods are twisted into a dense screw-like spiral; they are used for fodder and are sweet and nutritious, but smaller and less valuable than those of the mesquite.

For a fuller account of these trees see Charles Sprague Sargent, _Silva of North America_, iii. p. 99 (1892).

**MESS** (an adaptation of O. Fr. _mes_, mod. _mets_; Ital. _messio_; derived from the Late Lat. _missum_, past participle of _miltare_ "to send or place in position"), a service of meat, a dish sent to table. The term is also used of the persons who are in the habit of eating their meals together, and thus particularly of the parties into which a ship's company or a regiment is divided, which in turn are sometimes called mess. Originally, a mess in this sense was a group of four persons sitting at one table and helped from the same dishes. In the Inns of Court, London, the original number is preserved, four benches or four students dining together.

In early times the word mess was applied to food of a more or less liquid character, as soup, porridge, broth, &c. It is probably in allusion to the sloppy nature of semi-liquid messes of food that a mess has come also to mean a state of disorder, confusion and discomfort. Skeat takes the word in this sense to be a variant of "mash," originally to mix up.

**MESSAGE** (a word occurring in slightly different forms in several languages, e.g. Fr. _message_, Span. _mensaje_, Ital. _messaggio_; adapted from the Low Lat. _missaticum_, from _milleter_), a communication either verbal, written or printed, sent from one person to another. Message is the term generally applied to the official communications addressed by the heads of states to their legislatures at the opening of the session or at other times. These also, though written, are borne and delivered by special messengers and have the force of a face to face speech. The sessional and other messages to Congress of the president of the United States of America are printed state documents. Washington and John Adams delivered them in person but the practice was discontinued by Jefferson.

"Messenger" is of the same derivation; the earlier form of the word was _messagio_ (cf. passenger, scavenger). In ordinary language the word means one who is charged with the delivery of a message. In Scottish law a messenger-at-arms is an official appointed by Lyon-King-at-Arms to execute summonses and letters of diligence connected with the Court of Sessions and Court of Justiciary (see Wkr. § Scotland). Technically the term "messenger" is given to an endless rope or chain, passing from the capstan to the cable so that the latter may be hauled in when the messenger is wound round the capstan; also to a similar contrivance for hauling in a dredge.

**MESSAGER, ANDRE CHARLES PROSPER** (1853— ), French musician, was born at Montluçon on the 30th of December 1853; he studied at Paris, and in 1874 became organist at St. Sulpice. He was for some time a pupil of Saint-Saëns. In 1876 he won the gold medal of the Société des Compositeurs with a symphony. In 1880 he was appointed music director at St. Marie-des-Batignolles. In 1883 he completed Firmin Bernard's comic opera _Francois des bas bleus;_ and in 1885 produced his own operettas, _La Paouette du temple_ and _La Bérinarde_, the latter being performed in London in 1886. His ballet _Les Deux pigeons_ was produced at the Paris Opéra in 1886. But it was the production of his comic opera _La Bascoche_ in 1890 at the Opéra Comique (English version in London the following year) that established his reputation; and subsequently this was increased by such tuneful and tasteful light
the first example of an historical fresco at Rome. He is said
also to have brought the first sun-dial from Catana to Rome,
where it was set up on a column in the forum.

Polybius i. 16; Dion. Sic. xxiii. 4; Zonaras viii. 9; Pliny, Nat.
Hist., vii. 60, xxxv. 4 (7).

MESSALLINA, VALERIA, the third wife of the Roman
emperor Claudius (q.v.). She was notorious for her profligacy,
avarice and ambition, and exercised a complete ascendancy
over her weak-minded husband, with the help of his all-powerful
freedmen. During the absence of Claudius from the city,
Messallina forced a handsome youth named Gaius Silius to
divorce his wife and go through a regular form of marriage with
her. The freedman Narcissus, warned by the fate of another
freedman Polybius, who had been put to death by Messallina,
informing Claudius of what had taken place, and persuaded him
to consent to the removal of his wife. She was executed in
the gardens of Lucullus, which she had obtained on the death of
Valerius Asiaticus, who through her machinations had been
denounced on a charge of treason. She was only twenty-six
years of age. By Claudius she was the mother of the unfortunate
Britannicus, and of Octavia, wife of Nero.

See Tacitus, Annals, xi. 1-38; Dio. Cassius ix. 14-31; Livy
nu. 115-135, x. 333, xxxi. 341; Suetonius, Claudius; Merivale, Hist.
of the Romans under the Empire ch. 50; A. Stahr, "Agrippina" in
Bilder aus dem Alterthume, iv. (1865).

MESSAPII, an ancient tribe which inhabited, in historical
times, the south-eastern peninsula or "heel" of Italy, known
variously in ancient times as Calabria, Messapia and Iapygia.
Their chief towns were Uzentum, Rudiae, Brundisium and Uria.
They are mentioned (Herod. vii. 170) as having inflicted a serious
defeat on the people of Taras in 434 B.C. Herodotus calls them
a tradition which links them to the Cretan subjects of "King
Minos." Their language is preserved for us in a scanty group
of perhaps fifty inscriptions of which only a few contain more
than proper names, and in a few glosses in ancient writers
collected by Mommsen (Unteritalische Dialekte, p. 70). Unluckily
very few originals of the inscriptions are now in existence,
thought some few remain in the museum at Taranto. The only
satisfactory transcripts are those given by (1) Mommsen (loc.
cit.) and by (2) I. P. Dropo in the Annual of the British School
at Athens (1905-1906), xi. 137, who includes, for purposes of
comparision, as the reader should be warned, some specimens of
the unfortunately numerous class of forged inscriptions.
A large number of the inscriptions collected by Gumrini in the
apparatus of his Corpus inscriptionum italicarum are forgeries,
and the text of the rest is negligently reported. It is
therefore safest to rely on the texts collected by Mommsen,
 cumbered though they are by the various readings given to
them by various authorities. In spite, however, of these
difficulties some facts of considerable importance have been
established.

The inscriptions, so far as it is safe to judge from the copies
of the older finds and from Dropo’s facsimiles of the newer, are
all in the Tarentine-Ionic alphabet (with Ϝ for ε and ι for δ).
For limits of date 400-150 B.C. may be regarded as approximately
probable; the two most important inscriptions—those of
Bindisi and Vaste—may perhaps be assigned provisionally to
the 3rd century B.C.

Mommsen’s first attempt at dealing with the inscriptions and
the language attained solid, if not very numerous, results; chief
of which were the genitive character of the endings—idi and
idi; and the conjunctival value of indi (loc. cit. 79-84 sqq.).
Since that time (1850) very little progress has been made.
There is, in fact, only one attempt known to the present writer
to which the student can be referred as proceeding upon
thorough scientific lines, that of Professor Alf Torp in Indogermanische Forschungen (1895), v., 105, which deals fully with
the two inscriptions just mentioned, and practically sums up all
that is either certain or probable in the conjectures of his
predecessors. Hardly more than a few words can be said to
have been separated and translated with certainty—kolatoras (masc.
gen. sing.) “of a herald” (written upon a herald’s staff which
was once in the Naples Museum); aran (acc. sing. fem.) “a
able
land, *mesa*., 'greater' ( neut., acc. sing.), the first two syllables of the Latin *m aestas*; while *tepise* (3rd sing. aorist indic.) 'gave' or 'offered', and forms corresponding to the article (to = Greek θο) seem also reasonably probable.

Some phonetic characteristics of the dialect may be regarded as quite certain: (1) the change of the original short dio to d (as in the last syllable of the genitive kalatoras); (2) of final m to n (as in aran); (3) of -ei- to -ei- respectively to -nn- in -to and -nd- as in dazhomenes "Dasonis", dazohennii "Dasoni"; dazethes, gen. dazethini "Dazetius, Dazetii," from the shorter stem dazet; Vallaso for Vallasio (a derivative from the shorter name Valla); (4) the loss of final d (as in tepise), and probably of final t (as in des, perhaps meaning "set," from the root of Gr. πεδινο); (5) the change of original dh to d (anda = Gr. θαδα and bh to β (beran = Lat. ferar); (6) -au- before (at least some) consonants becomes -a- (Bästa, earlier Baśta). (7) Very great interest attaches to the form pentekaheis—which Torp very probably identifies with the Osan stem pompūo—which is a derivative of the Indo-European numeral *penke* "five.”

If this last identification be correct it would show that in Messenian (as in Venetic and Ligurian) the original velars were retained as gutturals and not converted into labials. The change of o to a is exceedingly interesting as being a phenomenon associated with the northern branches of Indo-European such as Gothic, Albanian and Lithuanian, and not appearing in any other southern dialect hitherto known. The Greek Ἰκρόπιαρτα appears in the form Aprodita (dat. sing., fem.). The use of double consonants which has been already pointed out in the Messenian inscriptions has been very acutely connected by Deecke with the tradition that the same practice was introduced at Rome by the poet Ennius who came from the Messapian town Rudiae (Festus, p. 293 M).

It should be added that the proper names in the inscriptions show the regular Italic system of gentle men precede by a personal praenomen; and that some inscriptions show the interesting feature which appears in the Tables of Heralcea of a crest or cost of arms, such as a triangle or an anchor, peculiar to particular families. The same reappears in the Ioviiae (q. s.) of Oppius and Famue.

For further information the student must be referred to the sources already mentioned and further to W. Deecke in a series of articles in the Rheinisches Museum, xxxvi. 576 sqq.; xxxvii. 373 sqq.; xl. 131 sqq.; xli. 226 sqq.; S. Bugge, Benzenberghs Beiträge, vol. 18. A manuscript publication has been published at Rome by Boblaye. New Dialekt, p. 31; for the Tarentine-Italic alphabet see ibid. ii. 461.

For a discussion of the important ethnological question of the origin of the Messapians see W. Helbig, Hermes, i. 257; P. Kretschmer, Einleitung in die Geschichte der griechischen Sprache, pp. 262 sqq. 272 sqq.; H. Hirt, Die sprachliche Stellung der Illyrischen (Festschrift für H. Kiepert, pp. 179-188). Reference should also be made to the discussion of their relation to the Veneti by C. Paula in "Die Beziehungen der römischen Volker" (Römische Forschungen, ital. Edition, p. 15). (R. S. C.)

MESSENE, an ancient Greek city, the capital of Messenia, founded by the Argives from the Peloponnesus, about the year 700 B.C., and first the Theban invasion of the Peloponnesian. The town was built by the combined Theban and Argive armies and the exiled Messenians who had been invited to return and found a state which should be independent of Spartan rule. The site was chosen by Epaminondas and lay on the western slope of the mountain which dominates the Messenian plain and culminates in the two peaks of Ithome and Euia. The former of these (2630 ft.) served as the acropolis, and was included within the same system of fortifications as the lower city.Messene remained a place of some importance under the Romans, but we hear nothing of it in medieval times and now the hamlet of Pamvotomai occupies a small part of the site.

Pausanias has left us a description of the city (iv. 31-33), its chief temples and statues, its springs, its market-place and gymnasium, its place of sacrifice (καταβολαι), the tomb of the hero Aristomenes (q.v.) and the temple of Zeus Ithomata on the summit of the acropolis with a statue by the famous Argive sculptor Ageladas, originally made for the Messenian helots who had sided at Naupactus at the close of the third Messenian War. But what chiefly excited his wonder was the strength of its fortifications, which excelled all those of the Greek world. Of the wall, some 5½ m. in extent, considerable portions yet remain, especially on the north and north-west, and almost the entire circuit can still be traced, affording the finest extant example of Greek fortification. The wall is flanked by towers about 31 ft. high set at irregular intervals: these have two storeys with loopholes in the lower and windows in the upper, and are entered by doors on a level with the top of the wall which is reached by flights of steps. Of the gates only two can be located, the eastern or Lacoonian, situated on the eastern side of the saddle uniting Ithome and Euia, and the northern or Arcadian gate. Of the former but little remains: the latter, however, is excellently preserved and consists of a circular court about 20 yds. in diameter with inner and outer gates, the latter flanked by square towers some 11 yds. apart. The interval of the inner gate was formed by a single stone 18 ft. 8 in. long, 5 ft. wide and 3 ft. high, or the mass of the circular court is of astonishing beauty and accuracy. The other buildings which can be identified are the theatre, the stadium, the council chamber or Bouleuterion, and the propylaeum of the market, while on the shoulder of the mountain are the foundations of a small temple, probably that of Artemis Laphria.

Blouet, Blouet, Caesar’s Description of the Expedition sc. de Moree, Architectura, i. 37-42, Plate 38-47; E. A. Boblaye, Recherches géogr. sur les ruines de la Morée, 107 sqq.; C. Bursian, Geographie von Griechenland, i. 163 sqq. (M. N. T.)

MESSENA (Gr. Μεσσήνη or Μεσσηνία), the S.W. district of the Peloponnesian, bounded on the E. by Mt Tágygetos, on the N. by the river Neda and the Arcadian Mountains, on the S. and W. by the sea. Its area is some 825,000 acres, considerably less than that of Shropshire or Wiltshire. Historically and economically its most important part is the great plain, consisting of two distinct portions, watered by the river Pamisus (Ouenissi) and its affluents. This is the most fertile tract in Greece, and at the present day produces oranges, citrons, almonds, figs, grapes and olives in great abundance and of excellent quality. The plain is bounded on the north by the Nomian Mountains (mod. Tetrádri, 5,070 ft.) and their westerly extension, on the west by the mountains of Cyperissi (4,000 ft.), a southern continuation of which forms the south-west peninsula of the Morea, attaining its greatest height in Mt Mathia (mod. Lykódimo 3160 ft.). Of the south coast of this peninsula lie the three Oenussae islands and the islet of Théganassu (Venetikó). In spite of its long coast-line, Messenia has no good harbours except the Bay of Pylos (Navarino), and has never played an important part in Greek naval history. The earliest inhabitants of Messenia are said to have been Pelasgians and Leleges (qq.v.), of whom the latter had their capital at Andania. Then came an Aeolio-Minyan immigration, which apparently extended to Messenia, though the Pylos of ancient times had its site in the south of the Morea, which in historic times bore that name. In the Homeric poems eastern Messenia is represented as under the rule of Menelaus of Sparta, while the western coast is under the Neleids of Pylos, but after Menelaus’s death the Messenian frontier was pushed earthwards as far as Tágygetos. A body of Dorian under Cresphontes invaded the country from Arcadia, and, taking-as their capital Stenacles in the northern plain, extended first their suzerainty and then their rule over the whole district. The task apparently proved an easy one, and the Dorians blending with the previous inhabitants produced a single Messenian race with a strong national feeling. But the fertility of the soil, the warm and genial climate, the mingling of races and the absence of opposition, combined to render the Messenians no match for their hardy and warlike neighbours of Sparta. War broke out—in consequence, it was said, of the murder of the Spartan king Teleclus by the Messenians—which, in spite of
Two generations later the Messenians revolted and under the leadership of Aristomenes (q.v.) kept the Spartans at bay for some seventeen years (648–631 B.C., according to Grote): but the stronghold of Iera (Eira) fell after a siege of eleven years, and those Messenians who did not leave the country were reduced to the condition of helots. The next revolt broke out in 464, when a severe earthquake destroyed Sparta and caused great loss of life; the insurgents defended themselves for some years on the rock-citadel of Ithome, as they had done in the first war; but eventually they had to leave the Peloponnese and were settled by the Athenians at Naupactus in the territory of the Locri Ozaeae. After the battle of Leuctra (371 B.C.) Epaminondas invited the exiled Messenians scattered in Italy, Sicily, Africa and elsewhere to return to their country: the city of Messene (q.v.) was founded in 360 to be the capital of the country and, like Megalopolis in Arcadia, a powerful check on Sparta. Other towns too were founded or rebuilt at this time, though a great part of the land still remained very sparsely populated. But though independent Messenia never became really powerful as an independent state it had an effect on the balance of power between the Theban power, to which it had owed its foundation, it became an ally of Philip II. of Macedon and took no part in the battle of Chaeronaea (338 B.C.). Subsequently it joined the Achaean League, and we find Messenian troops fighting along with the Achaeans and Antigonus Doson at Sellasia in 222 B.C. Philip V. sent Demetrius of Pharos to seize Messene, but the attempt failed and cost the life of Demetrius: soon afterwards the Spartan tyrant Nabis succeeded in taking the city, but was forced to retire by the timely arrival of the Philopoenae and the Megalopolitans. A war afterwards broke out with the Achaean League, during which Philopoenae was captured and put to death by the Messenians (183 B.C.), but Lycurgas took the city in the following year, and it again joined the Achaean League, though much weakened by the loss of Abia, Thuria and Phereas, which broke loose from it and entered the League as independent members (see Achaean League). In 146 B.C. the Messenians, together with the other states of Greece, were brought directly under Roman sway by L. Munius, and their former position had been a dispute between Messenia and Sparta about the possession of the Aer Denulesiac on the western slope of Taygetus: after various decisions by Philip of Macedon, Antigonus, Mummius, Caesar, Antony, Augustus and others, the question was settled in A.D. 25 by Tiberius and the Senate in favour of the rest of the Peloponnese. It was overrun by Slavic hordes, who have left their traces in many village names, and was one of the chief battlegrounds of the various powers—Byzantines, Franks, Venetians and Turks—who struggled for the possession of the Morea. Striking reminders of these conflicts are afforded by the extant ruins of the medieval strongholds of Kalatama, Coron (anc. Asine, mod. Korone), Monod (Methone) and Pylos. At the present day Messenia forms a department with its capital at Kalatama, and a population numbering (according to the census of 1907) 127,991.

(M. N. T.)

**MESSIAH**

(Dan. x. 25, 26), and **MESSIAH** (John i. 41; iv. 25), transcriptions (the first form modified by reference to the etymology) of the Greek Μεσσηας (Messias, Μεσιας), which in turn represents the Aramaic מֵשִׁיחָ (mēšiḥā), answering to the Hebrew מְשִׁיחָ (miššiḥa), “the anointed.” There can be no doubt that a magical power was ascribed to the anointing oil (cf. Ezra, Golden Bough, 2nd ed., ii. 354 sqq.). The king was thereby rendered sacred (1 Sam. xxiv. 6 sqq.; 2 Sam. i. 14 sqq.; iv. 9 sqq.), and he was considered to be endowed with a special virtue. Thus whosoever curses the king is stoned as though God Himself had been cursed (2 Sam. xix. 22). In ancient Egyptian cultus the priest, after he has solemnly saluted the gods, begins the daily toilet of the god, which consists in sprinkling his image, clothing it with coloured cloths, and anointing it with oil (Erman, Die ägyptische Religion, p. 49). In the magical texts of Babylonia a similar virtue was attached to oil: “bright oil, pure oil, expiatory oil that bestows magnificence on the Gods . . . the oil for the conjuration (ṣiptu) of Marduk” (Tallquist, Maklit series, tablet vii. col. 1, 37 sqq.; cf. Gressmann, Der Ursprung der israelitisch-jüdischen Eschatologie, p. 258, sqq.). We have, in Schrader's K.I.B. v. letter 37 (p. 98), evidence from the Tell el-Amarra tablets that the anointing of kings was practised in Egypt or Syria in 1450 B.C. (c.), in a letter addressed to the Egyptian king by Ramman-nirari of Nuḫāššīri. On the other hand even the initiatory and magical times subsisted between the sorcerer and the king see the citation from Frazer's Early History of Kingship, p. 127, in the article PRIEST, and cf. p. 29: “Classical evidence points to the conclusion that in prehistoric ages . . . the various tribes or cities were ruled by kings who discharged priestly duties” (p. 31). Thus the early kings of Assyria were priests of Assur (Ašur), the tutelary deity of Assyria. Tiglath-Pileser I. (c. 1100 B.C.) calls his predecessors, Šamši-Ramman and Išmi-Ḍagan, ḫ[lakh]u (pa-te-si) of the God Assur (Prism-insc. col. vii. 62, 63). Later kings, e.g. Shałmaneser II. (Nimrud-obelisk, line 15, monolith, line 11) and Ṣarur-bani-pal (Rassam cyl. col. vii. 94) call themselves by the more definite title of šangešu of Assur. The Hebrew word with the article prefixed occurs in the Old Testament only in the phrase “the anointed priest” (Lev. iv. 3, 5, 16; vi. 21, 13), but “Yahweh's anointed” is a common title of the king of Israel, applied in the historical books to Saul and David, in Lam. iv. 20 to Zedekiah, and in Isa. xlv. 1 extended to Cyrus. In the Psalms corresponding phrases (My, Thy, His anointed) occur nine times, which may be added the lyrical passages 1 Sam. ii. 18, Hab. iii. 13.

In the present attitude of literary criticism it would be most difficult to assert, as Robertson Smith did in the 9th edition of this work, that “in the intention of the writers it [i.e. the term messiay or “anointed”] refers to the king then on the throne.” Nor would most recent critics agree with Professor Driver (L.O.T., 8th ed. p. 385) in considering Pss. ii. and lxxii. as “presumably pre-exilic.” G. Buchanan Gray (J.Q.R., July 1895, p. 658 sqq.) draws a parallel between the “king” in the Psalms and the “servant” in Deutero-Isaiah or Yahweh's “Son” (in Hos. xi. 1, &c.) which is applied to Israel either actual or idealized. It would be possible so to interpret “king” or “anointed” in some Psalms, e.g. lxi. lxxiii. and lxxxiv., but hardly in Pss. lxxii. lxxiii. and lxxxiv., where the Messianic reference is strongly personal. In the Psalms the ideal aspect of the kingship, its religious importance as the expression and organ of Israel's sovereignty, is prominent. When the Psalter became a liturgical book the historical kingship had gone by, and the idea alone remained, no longer as the interpretation of a present political fact but as part of Israel's religious inheritance. It was impossible, however, to think that a true idea had become obsolete merely because it found no expression on earth for the time being; Israel looked again for an anointed king to whom the words of the sacred hymns should apply with a force

1. The transcription is as in Perseus Perseus for ἀνομασία, onomastika, ed. Lag., pp. 247, 261, Bca. βιλ. 3. For the termination as for ἀνομασία, see Lagarde, Palaeti, Memph., p. vii.

2. The plural is found in Ps. cv. 15, of the patriarchs as consecrated persons.

3. In Ps. lxxiii. 9 (10) it is disputed whether the anointed one is the king, the priest, or the nation as a whole. The second view is perhaps the best.
never related in the imperfect kingship of the past. Thus the Psalms were necessarily viewed as prophetic; and meantime, in accordance with the representation of ideal things as existing in heaven, the true king remains hidden with God. The steps by which this result was reached must, however, be considered in detail.

The hope of the advent of an ideal king was only one feature of that larger hope of the salvation of Israel from all evils, which was constantly held forth by all the prophets, from the time when the seers of the 8th century B.C. proclaimed that the true conception of Yahweh’s relation to His people could become a practical reality only through a great deliverance following a lifting judgment of the most terrible kind. The idea of a judgment so severe as to render possible an entire breach with the guilty past is common to all the prophets, but is expressed in a great variety of forms and images. As a rule the prophets directly connect the final restoration with the removal of the sins of their own age; to Isaiah the last troubles are those of Assyrian invasion, to Jeremiah the restoration follows on the exile to Babylon, to Daniel on the overthrow of the Greek monarchy. But all agree in giving the central place to the realization of a theocratic kingship, not in a temporal or political sense, but as the realization of the religious kingship of the nation of Israel, with a national organization under Yahweh as king, is common to the whole Old Testament, and connects prophecy proper with the so-called Messianic psalms and similar passages which speak of the religious relations of the Hebrew commonwealth, the religious meaning of national institutions, and so necessarily contain ideal elements reaching beyond the empirical present. All such passages are frequently called Messianic; but the term is more properly reserved as the specific designation of one particular branch of the Hebrew hope of salvation, which, becoming prominent in post-canonical Judaism, used the name of the Messiah as a technical term (which it never is in the Old Testament), and exercised a great influence on New Testament thought—the term “the Christ” (ὁ χριστός) being itself nothing more than the translation of “the Messiah.”

In the period of the Hebrew monarchy the thought that Yahweh is the divine king of Israel was associated with the idea of a kingship in which Yahweh reigns by right of being by commission or “unction” from Him. Such was the theory of the kingship in Ephraim as well as in Judah (Deut. xxxii.: 2 Kings ix. 6), till in the decedence of the northern state Amos (ix. 11) foretold the redintegration of the Davidic kingdom, and Hosea (iii. 5; viii. 4) expressly associated a similar prediction with the condemnation of the kingship of Ephraim as illegitimate. So the great Judaean prophets of the 8th century connect the salvation of Israel with the rise of a Davidic king, full of Yahweh’s Spirit, in whom all the energies of Yahweh’s transcendental kingship are as it were incarnate (Isa. ix. 6 sq.; xi. 1 sq.; Micah vi.). This conception, however, is not one of the constant elements of prophecy; other prophecies of Isaiah look for the decisive interposition of Yahweh in the crisis of history without a kingly deliverer. Jeremiah again speaks of the future David or righteous sprout of David’s stem (xxiii. 5 sq.; xxx. 9) and Ezekiel uses similar language (xxxiv., xxxvii.); but that such passages do not necessarily mean more than that the Davidic dynasty shall be continued in the time of restoration is proved by many texts in which Ezekiel speaks of the prince in chs. xlv., xlvii. As yet, however, we have no fixed doctrine of a personal Messiah, but only material from which such a doctrine might be drawn. The religious view of the kingship is still essentially the same as in 2 Sam. vii., where

the endless duration of the Davidic dynasty is set forth as part of Yahweh’s plan.

There are other parts of the Old Testament—notably 1 Sam. viii.-xii. (belonging to the later stria tum)—in which the very existence of a human kingship is represented as a departure from the theocratic ideal, and after the exile, when the monarchy had come to an end, we find pictures of the latter days in which its restoration has no place. Such is the great prophecy of Isa. xl.-xlviii., in which Cyrus is the anointed of Yahweh. So too there is no allusion to a human kingship in Joel or in Malachi; the old forms of the Hebrew state were broken, and religious hopes expressed themselves in other shapes. In the book of Daniel it is collective Israel that, under the symbol of a “son of man,” receives the kingdom (vii. 13, 18, 22, 27).

Meantime, however, the decay and ultimate silence of the living prophetic word concurred with prolonged political servitude to produce an important change in Hebrew religion. To the prophets the kingship of Yahweh was not a mere ideal, but an actual reality. Its full manifestation indeed, to the eye of sense and to the unbelieving world, lay in the future; but true faith found a present stay in the sovereignty of Yahweh, daily exercised, and expressed by the word of Yahweh in the form of the revealed King, with fullness of the voice of the prophets. And, while Yahweh’s kingship was a living and present fact, it refused to be formulated in fixed invariable shape.

But when the prophets were succeeded by the scribes, the interpreters of the written word, and the yoke of foreign oppressors rested on the land, Yahweh’s kingship, which presupposed a living nation, found not even the most inadequate expression in daily political life. Yahweh was still the lawgiver of Israel, but His law was written in a book, and He was not present to administer it. He was still the hope of Israel, but the hope too was only to be read in books, and these were interpreted of a future which was no longer the ideal development of forces already at work, but wholly new and supernatural. The present was a blank, in which religious duty was summed up in patient obedience to the law and penitent submission to the Divine chastisements. The scribes were mainly busied with the law; but no religion can exist on mere law; and the systematization of the prophetic hopes, and of those more ideal parts of the prophetic vision, was the real work of the scribes. Those prophecies, which, in the present, were now set on one line with the prophecies, went on side by side with the systematization of the law, by means of a harmonistic exegesis, which sought to gather up every prophetic image in one grand panorama of the picture of Israel’s and the world’s history. The beginnings of this process can probably be traced within the canon itself, in the book of Joel and the last chapters of Zechariah; and, if this be so, we see from Zech. ix. that the picture of the ideal king claimed a place in such constructions. The full development of the method belongs, however, to the post-canonical literature, and was naturally much less regular and rapid than the growth of the legal traditions of the scribes. It was in crises of national anguish that men turned most eagerly to the prophecies, and sought to construe their teachings as a promise of speedy deliverance (see Apocalyptic Literature). But these books, however influential, had no public authority, and when the yoke of oppression was lightened but a little their enthusiasm lost much of its contagious power. It is not therefore safe to measure the general growth of eschatological doctrine by the apocalyptic books, of which Daniel alone attained a canonical position. In the Apocalyptic eschatology has a relatively small place; but there is enough to show that the hope of Israel was never forgotten, and that the imagery of the prophets was accepted with a literalness not contemplated by the prophets themselves.

It was, however, only very gradually that the figure and name of the Messiah acquired the prominence which they have in

1 Most recent critics regard Amos ix.9-15 as a later addition, and the same view is held by Nowack, Harper and others respecting Hosea; but the ground is often questionable. Isa. ix. 1-7, xi. 1 sqq. are held by Hahmann, Cheyne, Marti, and other critics to be post-exilian. Dahm and others hold that they are genuine. It may be admitted that Isa. xi. 1 seq. might be held to be contemporary with Isa. lv. 3, 4, and to refer to Zerubbabel. Cf. Haggai ii. 21-23, composed seventeen years afterwards. Mic. v. 1-8 can with difficulty be regarded as genuine.

2 The hopes which Haggai and Zechariah connect with the name of Zerubbabel, a descendant of David, hardly form an exception to this statement. There may even be a reference to him in Isa. lv. 4, 5.

later Jewish doctrine of the last things and in the official exegesis of the Targums. In the very developed eschatology of Daniel they are, as we have seen, altogether wanting, and in the Apocrypha, both before and after the Maccabean revival, the everlasting throne of David's house is a mere historical reminiscence (Ecclus. xlvii. 11; 1 Macc. ii. 57). So long as the wars of independence occupied the Palestinian Jews, and the Hasmonaean sovereignty promised a measure of independence and felicity under the law, the hope that connected itself with the House of David was not likely to rise to fresh life, especially as a considerable proportion of the not very numerous passages of Scripture which speak of the ideal king might with a little straining be applied to the rising star of the new dynasty (cf. 1 Macc. xiv. 4–15). It is only in Alexandria, where the Jews were still subject to the yoke of the Gentile, that at this time (c. 140 B.C.) we find the oldest Sibylline verses (iii. 652 seq.) proclaiming the approach of the righteous king whom God shall raise up from the East (Isa. ii. 8). The name Messiah is still lacking, and the central point of the prophecy is not the reign of the deliverer but the subjection of all nations to the law and the temple. With the growing weakness and corruption of the Hasmonaean princes, and the alienation of a large part of the nation from their cause, the hope of a better kingship begins to appear in Judaea also; at first darkly shadowed forth in the Book of Enoch (chap. xc.), where the white steer, the future leader of God's herd after the deliverance from the heathen, stands in a certain contrast to the actual dynasty (the horned lambs); and then much more clearly, and for the first time with use of the name Messiah, in the Psalter of Solomon, the chief document of the protest of Pharisaism against its enemies the later Hasmonaeans. The struggle between the Pharisees and Sadducees, between the party of the scribes and the aristocracy, was a struggle for mastery between a secularized hierarchy whose whole interests were those of their own selfish politics, and a party to which God and the exact fulfilment of the law according to the scribes were all in one. This doctrine had grown up under Persian and Grecian rule, and no government that possessed or aimed at political independence could possibly show constant deference to the punctilios of the schoolmen. The Pharisees themselves could not but see that their principles were politically impotent; the most scrupulous observance of the Sabbath, for example—and this was the culminating point of legality—could not thrust back the heathen. Thus the party of the scribes, when they came into conflict with an active political power, which at the same time claimed to represent the theocratic interests of Israel, were compelled to lay fresh stress on the doctrine that the true deliverance of Israel must come from God.

But now the Jews, under their rulers and national ideas, came to the front. In the Hasmonaean sovereignty these ideas took a political form, and the result was the secularization of the kingdom of God for the sake of a harsh and rapacious aristocracy. The nation threw itself on the side of the Pharisees; not in the spirit of punctilious legality, but with the ardour of a national enthusiasm deceived in its deepest hopes, and turning for help from the delusive kingship of the Hasmonaeans to the true kingship of Yahweh, and to His vicegerent the king of David's house. It is in this connexion that the doctrine and name of the Messiah appear in the Psalter of Solomon. The eternal kingship of the House of David, so long forgotten, is seized on as the proof that the Hasmonaeans have no divine right.

1 Thou, Lord, art our king for ever and ever .... Thou didst choose out our father Leah his seed for ever that his kingdom should never fail before Thee. And for our sins sinners (the Hasmonaeans) have risen up over us, taking with force the kingdom which Thou didst not promise to the House of David and raiseth up the sitting of David in their place. Behold, O Lord, will cast them down and root out their seed from the land, when a man not of our race (Pompey) rises up against them. Behold, O Lord, and raise up your king the Son of David at the time that the nations are appointed, to reign over Israel Thy servant; and gird him with strength to crush unjust rulers; to cleanse Jerusalem from the heathen that tread it under foot, to cast out sinners from Thy inheritance: to break the pride of sinners and all their strength as potter's vessels with a rod of iron (Ps. ii. 9); to destroy the lawless nations with the word of his mouth (Isa. xi. 4); to gather a holy nation and lead them in righteousness. .... He shall divide them in the midst of the strong, and in the temple shall dwell with them; he shall judge the nations in wisdom and righteousness. The heathen nations shall serve under his yoke; he shall glorify the Lord before all the earth, and cleave to Jerusalem, as is written before. From the rising of the sun to the going down of the same shall come to see his glory and bring the weary sons of Zion as gifts (Isa. lx/3 seq.); to see the glory of the Lord with which God hath crowned him, for he is over them a righteous king taught of God. In the words of another of his psalms (cf. Ps. lxix. 19 seq.), he proves that in the midst of their enemies they are all holy and their king the anointed of the Lord (xptoris ἄνωθεν, mistranslation of הַמְּנָהשׁ); Psalt. Sol. xlvii.

This conception is traced in lines too firm to be those of a first essay; it had doubtless grown up as an integral part of the religious protest against the Hasmonaeans. And while the polemical motive is obvious, and the argument from prophecy against the legitimacy of a non-Davidic dynasty is quite in the manner of the scribes, the spirit of the theocratic fervour which inspires the picture of the Messiah is broader and deeper than their narrow legalism. In a word, the Jewish doctrine of the Messiah marks the fusion of Pharisaism with the national religious feeling of the Maccabean revival. This national feeling, claiming a leader against the Romans as well as deliverance from the Sadducee aristocracy, again sets the idea of the kingship rather than that of resurrection and individual redemption in the central place. Henceforward the doctrine of the Messiah is the centre of popular hope and the object of theological culture. The New Testament is the best evidence of its influence on the masses (see especially Matt. xxi. 9); and the exegesis of the Targums, which in its beginnings doubtless reaches back before the time of Christ, shows how it was fostered by the Rabbins and preached in the synagogues. Its diffusion far beyond Palestine, and in circles least accessible to such ideas, is proved by the fact that Philo himself (De praem. et premi. § 16) gives an account of the eschatological Messiah (cf. the LXX.), and must not indeed be supposed that the doctrine was as yet the undisputed part of Hebrew faith which it became when the fall of the state and the antithesis to Christianity threw all Jewish thought into the lines of the Pharisees. It has, for example, no place in the Assumption of Moses or the Book of Jubilees. But, as the fatal struggle with Rome became more and more imminent, the eschatological hopes which increasingly absorbed the Hebrew mind all group themselves round the person of the Messiah. In the later parts of the Book of Enoch (the "symbols" of chap. xiv. seq.) the judgment day of the Messiah (identified with Daniel’s "Son of Man") stands in the forefront of the eschatological picture. Josephus (B. J. vi. 5, § 4) testifies that the belief in the immediate appearance of the Messianic king gave the chief impulse to the war that ended in the destruction of the Jewish state; after the fall of the temple the last apostate (Baruch, 4 Ezra) still loudly proclaims the immediate kingship of the God-sent king; and Bar Cochebas, the leader of the revolt against Hadrian, was actually greeted as the Messiah by Rabbi Aqiba (cf. Luke xxi. 8). These hopes were again quenched in blood; the political idea of the Messiah, the restorer of the Jewish state, still finds utterance in the daily prayer of every Jew (the Shemone Eure), and is enshrined in the system of Rabbinical theology; but its historical significance was buried in the ruins of Jerusalem.

1 The Targumic passages that speak of the Messiah are registered by Buxtorf, Lex. Chalda., s. p. 180. The Messianic idea continued from time to time to appear among the Jews. Such was Serenus of Syria (c. 720 A.D.). Soon after, Messianic hopes were active at the time of the fall of the Omayyads, and led to a serious rising under Abu ‘Isa of Isphanah, while a Jewish rabbi of the name of Messiah Miqva‘ah appeared in the reformed kingdom of the Messianic Sifre. Another has been discovered by Zimmermann. The false Messiah David Alroi (Alroy) appeared among the warlike Jews in Azerbaijan in the middle of the 12th century. The Messianic claims of Abraham Altabba of Saragossa (born 1240) had a catastrophic basis, and the most stupendous and the oldest hopes at a time. Thus the Ababbanab calculated the coming of the Messiah for 1503 A.D.; the year 1500 was in many places observed as a preparatory season of penance; and throughout the 16th century the Jews were much stronger and more than one false Messiah appeared. See also SABBATAI, SEBI.
This but this that the true kingdom of God could not be realized in an earthly state, under the limitations of national particularism, was not the final refutation of the Old Testament hope. Amidst the last convulsions of political Judaism a new spiritual conception of the kingdom of God, of salvation, and of the Saviour of God's anointing, had shaped itself through the preaching, the death, and the resurrection of Jesus of Nazareth. As applied to Jesus the name of Messiah lost all its political and national significance. Between the Messiah of the Jews and the Son of Man who came to give His life a ransom for many there was on the surface little resemblance; and from their standpoint the Pharisees reasoned that the marks of the Messiah were conspicuously absent from this Christ. But when we look at the deeper side of the Messianic conception in the Psalter of Solomon, at the heartfelt longing for a leader in the way of righteousness and acceptance with God which underlies the aspirations after political deliverance, we see that it was in no mere spirit of accommodation to prevailing language that Jesus did not disdain the name in which all the hopes of the Old Testament were gathered up.

Messianic Parallels.—Within the limits of this article it is impossible to attempt any extended survey of parallels to Hebrew Messianic ideas found in other religious system. The interesting analogy communicated by Professor Rapson, may, however, be cited from the Bhagavad-gitâ, iv. 8, in which Krishna says:

5 "Many are the births that have passed of me and of thee

Arihanta

All these I know: thou knowest them not, O conqueror of thy foes.

6. Unborn, of imperishable soul, the Lord of all creatures,

Taking upon me own nature, I abide by my own power.

7. For whenever, O son of Bharata, there is decay of righteousness
And a rising up of unrighteousness, then I create myself,
For the protecting of the good and for the destroying of evil-doers.

8. And for the establishing of righteousness I arise from age to age.

"Something similar are the avatars of Vishnu, who becomes incarnate in a portion of his essence on ten occasions to deliver mankind from certain great dangers. Krishna himself is usually regarded as one of these avatars. This we may consider as one of the striking parallels which meet us in other religions to that hope of the advent of an ideal king which was one of the features of that larger hope of the salvation of Israel from all evils, the realization of perfect reconciliation with Jehovah and the felicity of the righteous in Him, to which reference was made in an early portion of this article and which constitutes the essential meaning of the Messianic hope. The form in which the Indian conception presents itself in the above quoted lines is more closely analogous amid many differences to the later and apocalyptic type of the Messianic idea as it appears among the Jews.

The interesting parallels between the Babylonian Marduk (Merodach) god of light and Christ as a world saviour are ingeniously set forth by Zimmer in K.A.T., 3rd ed., pp. 376-391, but the treatment does not embrace all men or only the righteous, whether it precedes or follows the Messianic age. Compare Millennium.

We must also pass over the very important questions that arise as to the gradual extrication of the New Testament idea of the Christ from the elements of Jewish political doctrine which had so strong a hold of many of the first disciples—the relation, for example, of the New Testament Apocalypse to contemporary Jewish thought. A word, however, is necessary as to the Rabbinical teaching of the Messiah. There is certain evidence that the Messiah, son of Joseph or son of Ephraim, who in Jewish theology is distinguished from and subordinate to the victorious son of David. The developed form of this idea is almost certainly a product of the period with Chaldisch-Babylonian influence. The Pharisees were hard pressed by arguments from passages (especially Isa. lxi.) which their own exegesis admitted to be Messianic, though it did not accept the Christian inferences as to the atoning death of the Messiah. The Pharisees were impressed with a suffering and atoning Messiah is, to say the least, unproved and highly improbable. See, besides the books above cited, De Wette, Opuscula; Wünsche, Die Leiden des Messias (1870).

See the article "Messiah" in Hastings's D. B. (together with Forbush) and the development of Doctrine, in extra vol., pp. 295-302 in Encyc. Bibl. (W. R. S.; O. C. W.)

MESSINA, a city of Sicily, 7 m. S.S.W. of the promontory of Faro (anc. Promontorium Pelorun), which forms the north-eastern angle of the island, the capital of the province of Messina and the seat of an archbishop. Pop. (1890), 97,074; (1881), 126,407; (1901), 149,778; (1905), 158,812. The site of the town curves round the harbour, between it and the strongly fortified hills of Anticamare, the highest point of which is 3707 ft. The straits, which take their name from the town, are here about 33 m. wide, and only a little over 2 m. at the promontory of Faro. The numerous earthquakes from which the city had suffered, notably that in 1755, had left it few remnants of antiquity. But it was a flourishing and beautiful city when in 1908 one of the most disastrous earthquakes ever recorded destroyed it totally. The earthquake occurred early in the morning of December 28, and so far as Messina was concerned the damage was done chiefly by the shock and by the fires which broke out afterwards; the seismic wave which followed was comparatively innocuous. But it did vast damage elsewhere along the strait, notably at Reggio, Calabria, which was also totally destroyed. Many other smaller towns suffered both in Sicily and in Calabria; the loss of life was appalling and the distress widespread, in spite of the prompt assistance rendered by Italian naval and military forces and by the crews of British, Russian and German warships and other vessels, and the contribution of funds for relief works from every part of the world. The immediate seismic focus appeared to be in the straits, but Dr E. S. Sessou pointed out that it was surrounded by a curved line of earth-fracture, following an arc drawn from a centre in the Lipari Islands, from Catanza to Etna, and so westward to the Straits of Messina. The earthquake was caused by an earth tremor, together with a small wave impinging on the coast and causing heavy damage, and in an unstable condition. According to an official estimate the earthquake caused the loss of 77,235 lives. (See also EARTHQUAKE.)

The façades of buildings at Messina in great part withstood the earthquake, but even when they did so the remainder of the buildings was destroyed. The cathedral, which was completely wrecked, was begun in 1098 and finished by Roger II. It had a fine Gothic façade: the interior had mosaics in the apses dating from 1330, and the nave contained 26 granites columns, said to have been brought from a temple of Poseidon near Faro, and had a fine wooden roof of 1260. The rest of the edifice was in the baroque style; the high altar (containing the supposed letter of the Virgin Mary to the people of Messina), richly decorated with marbles, lapis lazuli, &c., was begun in 1628 and completed in 1726. The importance of Messina was almost entirely due to its

harbour, a circular basin open on the north only, formed by a strip of land curving round like a sickle, from which it took its original name, *Zancle* (γανκλε, or rather δάγκλε, the Sicilian equivalent of the Greek δακτύλος, according to Thucydidès, vi. 4).

Zancle was first founded, doubtless on the site of an earlier settlement, by pirates from Cumae, and again more regularly settled, after an unknown interval, by settlers from Cumae under Perieres, and from Chalcos under Cretanemes, in the first quarter of the 8th century B.C. Myales must have been occupied as an outpost very soon afterwards, but the first regular colony of Zancle was Himera, founded in 648 B.C. After the capture of Milethus by the Persians in 494 B.C. Skyes, king of Zancle, invited the Ionians to come and settle at Καλή 'Αστύ, then in the occupation of the Sicels (the modern Marina di Cariolà, 25 m. east of Cefalù); but at the invitation of Anaxilus of Regium the Samians proceeded instead to the latter place. About 488 B.C. Anaxilas and the Samians occupied Zancle in the absence of Skyes, and it was then that the name was changed to Messene, as the existence of coins of the Samian type, bearing the new name, proves. About 480 B.C., however, Anaxilas had sufficiently established his authority at Messene, and the types of coinage introduced by him were so close to 490 B.C., when Anaxilas himself zealously supported his son-in-law Terillus in invading the Carthaginians' invasion of 480 B.C. In 426 the Athenians gained the alliance of Zancle, but soon lost it again, and failed to obtain it in 415.

Messina fell into the hands of the Carthaginians during their wars with Dionysius the elder of Syracuse (397 B.C.). The Carthaginians destroyed the city, but Dionysius recaptured and rebuilt it. During the next fifty years Messina changed masters several times, till Timoleon finally expelled the Carthaginians in 343 B.C. In the wars between Agathocles of Syracuse and Carthage, Messina took the side of the Carthaginians. After Agathocles' death, his mercenaries, the Mamertines, treacherously seized the town about 282 B.C. and held it. They came to war with Hiero II. of Syracuse and appealed for help to Rome, which was granted, and this led to a collision between Rome and Carthage, which ended in the First Punic War. Messina was almost at once taken by Rome. At the close of the war, in 241 B.C., Messina became a free and allied city (civitas foederata), and obtained Roman citizenship before the rest of Sicily, probably from Caesar himself. During the civil wars which followed the death of Caesar, Messina held with Sextus Pompeius; and in 35 B.C. it was sacked by Octavian's troops. After Octavian's proclamation as emperor he founded a colony here; and Messina continued to flourish as a trading port. In the division of the Roman empire it belonged to the emperors of the East; and in A.D. 547 Belisarius collected his fleet here before crossing into Calabria. The Saracens took the city in A.D. 831; and in 1061 it was the first permanent conquest made in Sicily by the Normans. In 1190 Richard I. of England, with his crusaders, passed six months in Messina. He quarrelled with Tancredi, the last of the Hauteville dynasty, and sacked the town. In 1194 the city, with the rest of Sicily, passed to the house of Hohenstaufen under the emperor Henry VI., who died there in 1197; and after the fall of the Hohenstaufen was contented for by Peter I., king of Aragon, and Charles I., count of Anjou. At the time of the Sicilian Vespers (1282), which drove the French out of Sicily, Messina bravely defended itself against Charles of Anjou, and repulsed his attack. Peter I., through his commander Ruggiiero di Loria, defeated the French off the Faro; and from 1282 to 1713 Messina remained a possession of the Spanish royal house. In 1571 the fleet fitted out by the Holy League against the Turk assembled at Messina, and in the same year its commander, Don John of Austria, celebrated a triumph in the city for his victory at Lepanto. Don John's statue stands in the Piazza dell' Annunziata. For one hundred years, thanks to the favours and the concessions of Charles V., Messina enjoyed great prosperity. But the internal quarrels between the Merli, or aristocratic faction, and the Malvezzi, or democratic faction, fostered as they were by the Spaniards, helped to ruin the city (1671-1678).

The Messinians suspected the Spanish court of a desire to destroy the ancient senatorial constitution of the city, and sent to France to ask the aid of Louis XIV. in their resistance. Louis despatched a fleet into Sicilian waters, and the French occupied the city. The Spaniards replied by appealing to Holland, who sent a fleet under Ruyter into the Mediterranean. In 1676 the French admiral, Abraham Duquesne, defeated the combined fleet of Spain and Holland; but, notwithstanding this victory, the French suddenly abandoned Messina in 1678, and the Spanish occupied the town once more. The senate was suppressed, and Messina lost its privileges. This was fatal to the importance of the city. In 1743 the plague carried off 40,000 inhabitants. The city was partially destroyed by earthquake in 1783. During the revolution of 1848 against the Bourbons of Naples, Messina was bombarded for three consecutive days. In 1864 the deaths from cholera numbered about 15,000. Garibaldi landed in Sicily in 1860, and Messina was the last city in the island taken from the Bourbons and made part of united Italy under Victor Emmanuel.

Messina was the birthplace of Dicaearchus, the historian (c. 322 B.C.); Aristotle, the Peripatetic; Euhemerus, the rationalist (c. 316 B.C.); Stefano Protonotario, Mazzaro di Ricco and Tommaso di Sasso, poets of the court of Frederick II. (A.D. 1250); and Antonio di Messina, the painter (1447-1499), of whose works one is preserved in the museum. During the 15th century the grammarian, Constantine Lascaris, taught in Messina; and Bessarion was for a time archimandrite there.

**MESSUE**—**METABOLIC DISEASES**

Messa was the birthplace of Dicaearchus, the historian (c. 322 B.C.); Aristotle, the Peripatetic; Euhemerus, the rationalist (c. 316 B.C.); Stefano Protonotario, Mazzaro di Ricco and Tommaso di Sasso, poets of the court of Frederick II. (A.D. 1250); and Antonio di Messina, the painter (1447-1499), of whose works one is preserved in the museum. During the 15th century the grammarian, Constantine Lascaris, taught in Messina; and Bessarion was for a time archimandrite there.

**MESSUE** (from Anglo-French messue, probably a corruption of messue, ménage, popular Lat. mansio, whence mod. Fr. maison, from manere, to dwell), in law, a term equivalent to a dwelling-house, and including outbuildings, orchard, curtilage or court-yard and garden. At one time 'messue.' is supposed to have had a more extensive meaning than that comprised in the word 'house,' but such distinction, if it existed, no longer survives.

**MESTIZO** (adopted from the Spanish, the Portuguese form being mestico, from Lat. miscere, to mix), a term originally meaning a half-breed, one of whose parents was Spanish, and now used occasionally of any half-breed, but especially to denote persons of mixed Spanish (or Portuguese) and American Indian blood. The offspring of such half-breeds are also called mestizos. The feminine form is mestiza.

**MESUREUR, GUSTAVE EMIL EUGÈNE** (1847— ), French politician, was born at Marcq-en-Barœul (Nord) on the 2nd of April 1847. He worked as a designer in Paris, and became prominent as a member of the municipal council of Paris, rousing much angry discussion by a proposal to rename the Parisian streets which bore saints' names. In 1887 he became president of the council. The same year he entered the Chamber of Deputies, taking his place with the extreme left. He joined the L. Bourgeois ministry of 1895-1896 as minister of commerce, and the next year he was postmaster-general, and in 1897 was vice-president of the Chamber from 1898 to 1902, and presided over the latter. Commission of 1899, 1901 and 1902. He was defeated at the polls in 1902, but became director of the Assistance Publique. His wife, Amélie de Wailly (b. 1853), is well known as a writer of light verse and of some charming children's books.

**META** (from Greek meta, change), in chemistry, the chemical changes in the protoplasm of some or all of the tissues of the body. While in some pathological states these modifications lead to structural changes, in others they do not produce gross lesions, and these latter conditions are commonly classified as Functional Diseases. When such
functional disturbances affect the general nutrition of the body
they have been termed Metabolic Diseases (Stoffwechselkrank-
heiten). It is impossible to draw a hard and fast line between
functional and organic disease, since the one passes gradually
into the other, as is well seen in gout. Nor is it always easy
to decide how far the conditions are due merely to quantitative
alterations in the metabolism and how far to actual qualitative
changes, for it is highly probable that many of the apparently
qualitative alterations are really quantitative disturbances in
one part of the protoplasmic mechanism, leading to an apparent
qualitative change in the total result of the activity.

Obesity.—It is as fat that the surplus food absorbed is stored
in the body; but the power of storing fat varies enormously
in different individuals, and in some it may be considered patho-
logical. The reasons of this are very imperfectly understood.
One undoubted cause of obesity is taking a supply of food in
excess of the energy requirements of the individual. The
amount of food may be absolutely large, or relatively
the muscular energy evolved in mechanical work or in heat-produ-
cion; but in either case, when fat begins to be deposited, the
muscular activity of the body tends to diminish and the loss of
heat from the surface is reduced; and thus the energy
requirements become less, and a smaller diet is sufficient to yield
the surplus for further storage of fat. Fat is formed from carbo-
hydrates, and possibly indirectly from proteins (see NUTRITION).
Individuals probably vary in their mode of dealing with these
substances, some having the tendency to convert them to fat,
some to burn them off at once. Carl von Noorden, however,
who has studied the metabolism in cases of obesity, finds no
marked departure from the normal. It may be that in some
persons there is a very perfect absorption of food, but so far no
scientific evidence for this view is forthcoming. In all cases the
fat stored is available as a source of energy, and this circum-
stance is taken advantage of in the various fat "cures," which
consist in giving a diet containing enough proteins to cover the
requirements of the body, with a supply of fats and carbohydrates
insufficient to meet the energy requirements of the individual.
This is illustrated by the dietaries of some of the best known of
these "cures":

| In Grms. per Diem. | Proteid. | Fat. | Carbo-
|-------------------|---------|------|hydrates. |
| Banting's cure     | 172     | 8    | 81     | 1112    |
| Oertel's          | 156-170 | 25-45| 75-120 | 1180-1608 |
| Ebstein's         | 102     | 85   | 47     | 1401    |

In a normal individual in moderate muscular activity about
3000 Calories per diem are required (see DIETETICS), and there-
fore under the diets of these "cures," especially when accompa-
nied by a proper amount of muscular exercise, the fats stored
in the body are rapidly used up.

Diabetes, as distinguished from transitory glycosuria, is pro-
duced by a diminution in the power of the tissues to use sugar,
which accumulates in the blood and escapes in the urine.
One great source of energy being unavailable, the tissues have to
use more fats and more proteins to procure the necessary energy,
and hence, unless these are supplied in very large quantities,
there is a tendency to emaciation.

The power of storing and using sugar in the tissues is strictly
limited, and varies considerably in healthy individuals. Normally,
when about 200 grms. of glucose are taken at one time, some
of it appears in the urine within one hour. In some individuals
the taking of even 100 grms. leads to a transient glycosuria,
while others can take 250 grms. or more and use it all. But even
in the same healthy individual the power of using sugar varies
at different times and in different conditions, muscular exercise
markedly increasing the combustion. Again, some sugars are
more readily used than others, and therefore have a less tendency
to appear in the urine when taken in the food. Milk-sugar and
lactose appear in the urine more readily than glucose. This
power of using sugar possessed by an individual may depend to a
small extent on the capacity of the liver to store as glycogen any
excess of carbohydrates absorbed from the food, and some slight
cases of transient glycosuria may be accounted for by a dimin-
uition of this capacity. But the typical form of diabetes cannot
be thus explained. It has been maintained that increased
production of sugar is a cause of some cases of the disease, and
this view has been supported by Claude Bernard's classical
experiment of producing glycosuria by puncturing the floor of
the fourth ventricle in the brain of the rabbit. But after such
puncture the glycosuria occurs only when glycogen is present in
the liver. It is transient and has nothing to do with true
diabetes. The fact that various toxic substances, e.g. carbon
monoxide, produce glycosuria has been used as an argument in
support of this view, but they too seem to act by causing a
conversion of glycogen to glucose, and are effective only when
the liver is charged with the former substance. At one time it was
thought that the occurrence of glycosuria under the admini-
stration of phloridzin proved that diabetes is due to a poison.
But the fact that, while sugar appears abundantly in the urine
under phloridzin, it is not increased in the blood, shows that the
sugar is utilized by diminishing the power of the tissues to use sugar,
but by increasing the excretion of sugar through the kidneys
and thus causing its loss to the body. Hence the tissues have to fall
back upon the proteids, and an increased excretion of nitrogen
is produced. This, however, is a totally different condition from
diabetes.

Anything which produces a marked diminution in the normally
limited power of the tissues to use sugar will cause the disease
in a lighter or graver form. As age advances the activity of the
various metabolic processes may diminish irregularly in certain
individuals, and it is possible that the loss of the power of using
may be sooner impaired in some than in others, and thus
diabetes be produced. But Minkowski and von Mering have
demonstrated, by experiments upon animals, that pathological
changes in the pancreas have probably a causal relationship
with the disease. They found that excision of that organ in
dogs, &c., produced all the symptoms of diabetes—the appear-
ance of sugar in the urine, its increased amount in the blood,
the rapid breaking-down of proteids, and the resulting emaciation
and azoturia. At the same time the absorption from the intestine
of proteids, fats and carbohydrates was diminished. How this
pancreatic diabetes is produced has not been explained. It has
been suggested that the pancreas forms an internal secretion
which stimulates the utilization of sugar in the tissues. Though
in a certain number of cases of diabetes disease of the pancreas
has been found, other cases are recorded where grave disease
of that organ has not produced this condition. But the apparent
extent of a lesion is often no measure of the depth to which the
functions of the structure in which it is situated are altered, and
it is very possible that the functions of the pancreas may in
many cases be profoundly modified without our methods of
research being able to detect the change. The pancreas consists
of two parts, the secreting structure and the epithelial islets, and
one or other of these may be more specially involved, and thus
alteration in digestion and absorption on the one hand, and
changes in the utilization of carbohydrates on the other, may be
separately produced. The subcutaneous injection of large doses
of extracts of the supra-renal bodies causes glycosuria and an
increase of sugar in the blood, but the relationship of this con-
dition to diabetes has not yet been investigated.

The disease may be divided into two forms:—
1. Slight Cases.—The individual can use small quantities of sugar,
but the taking of larger amounts causes glycosuria. Supposing
that the energy requirements of an individual are met by a diet of—

<table>
<thead>
<tr>
<th></th>
<th>Proteid.</th>
<th></th>
<th>Fat.</th>
<th></th>
<th>Carbohydrate</th>
<th>Calories.</th>
</tr>
</thead>
<tbody>
<tr>
<td>100 grms.</td>
<td>410</td>
<td>930</td>
<td>1640</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

then if only 100 grms. of glucose can be used, the energy value of
300 grms., i.e. 1230 Calories, must be supplied from proteids and
fats. To yield this, 300 grms. of proteids or 132 grms. of fats would
be required. If these are not forthcoming in the diet, they must
be supplied from the tissues, and the individual will become emaciated; hence a diabetic on an ordinary diet is badly nourished, and hence the huge appetite characteristic of the disease.

2. Grave Cases.—From the products of the splitting of proteids sugars and phosphates, and the by-products of decomposition of the fatty forms of the disease, even when carbohydrates are excluded from the food, a greater or lesser quantity of the sugar thus formed escapes consumption and may be excreted. Theoretically, 100 grms. of proteids yield 65 grms. of sugar, i.e. 1 grm. of sugar will be set free for each 7.5 grms. of glucose formed. In the urine of grave cases of diabetes on a proteid diet, the proportion of nitrogen to sugar is about 1 to 2. This may mean that the theoretically possible sugar is not all used, that some is formed in the body, and that some is formed in the economy. Both hypotheses may be correct, but the latter is supported by the fact that even in grave cases the decomposition of proteids may be diminished by giving sugar, and that the amount of sugar in the urine may fall.

In the course of the disease the amount of sugar which the tissues can use varies from day to day. It is in the utilization of glucose—the normal sugar of the body—that the tissues chiefly fail. Many diabetics are able to use laevulose, and the inulin from which it is derived, and lactose (milk-sugar) to a certain extent. It has, however, been observed that under the administration of these sugars the excretion of glucose may be increased, the tissues apparently using the foreign sugar, allowing part of the glucose when they would have set it free. The increased decomposition of proteid, rendered necessary to supply the energy not forthcoming in the sugar, leads to the appearance of the nitrogen of the proteid in the urine, and it also leads to the formation of various acids. Sulphuric acid and phosphoric acid are formed by oxidation of the sulphur and phosphorus in the proteid molecule. Organic acids of the lower fatty acid series \( \beta \) oxobutyric and aconato-acetic acid with their derivative acetone bodies also appear in the urine of diabetics. These acids are in part formed from the disintegration of proteids and in part fats, as the result of a modified metabolism induced by the withdrawal of carbohydrates. To neutralize then ammonia is developed and hence the proportion of ammonia in the urine is increased. But the development of these various acids the alkalinity of the blood is diminished. The development of these acids in large quantities is associated with extensive decomposition of proteid, and is sometimes the first symptom of a comatose condition, which seems to be due rather to an acid intoxication than to the special toxic action of any particular acid.

Myxoedema.—The thyroid gland forms a material which has the power of increasing the metabolism of proteids and of fats; and when the thyroid is removed, a condition of sluggish metabolism, with low temperature and a return of the connective tissues, supervenes, accompanied by the appearance of depression of the mental functions and by other nervous symptoms. The disease myxoedema, which was first described by Sir William Gull in 1873, was shown by Ord in 1887 to be due to degenerative changes in the thyroid gland. It affects both sexes, but chiefly females, and is characterized by a peculiar puffiness of the face and hands, shedding of the hair, a low temperature, and mental hebetude. The symptoms are similar to those produced by removal of the thyroid, and are indicative of a condition of diminished activity of metabolism. The nervous symptoms may be in part due to some alteration in the metabolism, leading to the formation of toxic substances. The administration of thyroid gland extract causes all the symptoms to disappear.

Cretinism may now be defined as myxoedema in the infant, and it has been definitely proved to be associated with underdevelopment or degeneration of the thyroid gland. The characteristic features of all metabolic disease, leading to retarded development, and the treatment which has proved of service, at least in some sporadic cases, is the administration of various thyroid preparations.

Exophthalmic Goitre—Graves's Disease or Basedow's Disease.—This disease chiefly affects young women, and is characterized by three main symptoms: increased rate and force of the heart's action, protrusion of the eyeballs, and enlargement of the thyroid gland. The patient is nervous, often sleepless, and generally becomes emaciated and suffers from slight febrile attacks. The increased action of the heart is the most constant symptom, and the enlargement of the thyroid gland may not be manifest. Various theories as to the pathology of the condition have been advanced, but in the light of our knowledge of the physiology of the thyroid the most probable explanation is an increased functional activity of that gland or of changes in the parathyroids.

Gout has often been divided into the typical and atypical forms. The first is undoubtedly a clinic and pathological entity, but the second, though containing cases of less severe forms of true gout, is largely constituted of imperfectly diagnosed morbid conditions. The accumulation of urate of soda in the tissues of gout formerly led physicians to believe in a causal relationship between an increased formation of that substance and the onset of the disease. Sir A. Garrod's investigations, however, seemed to indicate that diminished excretion rather than increased production is the cause of the condition. He found an accumulation of uric acid in the blood and a diminution in its amount in the urine during the attack. That uric acid is increased in the blood is undoubtedly, but the changes described by Garrod in the urine, and considered by him as indicative of diminished excretion and retention, are rendered of less value by the imperfections of the analytic method employed. More recent work with better methods has thrown still further doubt upon the existence of such a relationship, and points rather to the accumulation of uric acid being, like the other symptoms of the condition, a result of some unknown modification in the metabolism, and a purely secondary phenomenon. The important fact that in leucæma (von Jaksch), in lead-poisoning (Garrod), and in other pathological conditions, uric acid may be increased in the blood and in the urine without any gouty symptoms supervening, is one of the strongest arguments against the older views. That the gouty inflammation is not caused by the depositions of urate of soda, seems to be indicated by the occurrence of cases in which there is no such deposition. The source of the uric acid which is so widely deposited in the gouty is largely the phosphorus containing nucleins of the food and tissues. These in their decomposition yield a series of di-ureides, the purin bodies, of which uric acid is one. Their excretion is increased when substances rich in nuclein, e.g. sweetbreads, &c., are administered. While uric acid itself has not been demonstrated to have any injurious action, the closely allied adenin has been found to produce toxic symptoms. After the discovery of this source of uric acid, physiologists for a time inclined to regard it as the only mode of production. But it must be remembered that in birds uric acid is formed from the ammonia compounds coming from the intestine and muscles, just as urea is formed from the same substance in mammals. Uric acid is a di-ureide—a body composed of two urea molecules linked by acrylic acid—an unsaturated propionic acid. It is therefore highly probable that in many conditions the conversion of ammonia compounds to urea is not complete, and that a certain amount of uric acid is formed apart from the decomposition of nucleins.

Sir William Roberts has adduced evidence to show that uric acid circulates in the blood in a freely soluble combination or quadrature—that is, a compound in which one molecule of an acid salt BH\(_4\)H is linked to a molecule of the acid BH\(_4\)H.\(_2\)H\(_2\). These compounds are said to be readily decomposed and the bi-urates, formed, which are at first gelatinous but become crystalline. The deposition of urate of soda in joints, &c., has been ascribed to the effects of such compounds. Further support for this view comes from the results of certain investigations which throw doubt upon this explanation. The most recent investigations on the metabolism of the gouty have shown that there is undoubtedly a slowing in the rate of elimination of uric acid and also of the total nitrogen of the urine with occasional sudden increases sometimes connected with a gouty paroxysm, sometimes independent of it. Whether this is due to the action of some toxin developed in the body or is caused by a constitutional renal inactivity is difficult to decide. Certainly it is these renal diseases often develop in the course of gout.

Rheumatism.—Rheumatic fever was formerly regarded as due to some disturbance in the metabolism, but it is now known to be a specific micro-organisinal disease. The whole clinical picture is that of an infective fever, and it is closely related to gonorrhoeal rheumatism and to certain types of pyaemia. A number of independent observers have succeeded in isolating from cases of rheumatic fever a diplococcus which produces similar
symptoms in the rabbit to those which characterize the disease in man.

Excluding the peculiar changes in the joints which occur in rheumatoid arthritis and in Charcot's disease, and which are almost certainly primary affections of the nervous system, it is found that a large number of individuals suffer from pain in the joints, in the muscles, and in the fibrous tissues, chiefly on exposure to cold and wind, or after indiscretions of diet. This so-called chronic rheumatism appears to be a totally distinct condition from rheumatic fever; and although its pathology is not determined, it looks as if it were due either to a diminished elimination or an increased production of some toxic substance or substances, but so far we have no evidence as to their nature.

Rickets is undoubtedly a manifestation of a profound alteration of the metabolism in childhood, but how far it is an idiopathic condition and how far a result of the action of toxins introduced from without is not yet definitely known. Kassowitz long ago showed that the bone changes are similar to those which can be produced in animals by chronic phosphorus poisoning, and that they are really irritative in nature. Spillmann, in his work Le Rachitisme, discusses the evidence as regards the action of various conditions, and comes to the conclusion that there is no evidence that it is due to a mere primary disturbance of the metabolism, or to excessive production of lactic acid, or to any specific micro-organismal poisoning. But he adds evidence, perhaps not very convincing, that in the disease there is a specific intoxication derived from the alimentary canal and provoking inflammatory lesions in the bones.

See generally Carl von Noorden, Metabolism and Practical Medicine (1907). (D. N. P.)

METABOLISM (from Gr. μεταβολή, change), the biological term for the process of chemical change in a living cell (see PHYSIOLOGY).

METAL (through Fr. from Lat. metallum, mine, quarry, adapted from Gr. μεταλλία, in the same sense, probably connected with μετάλλαω, to search after, explore, μερίκω, after, ἀξίω, value, other). Originally applied to gold, silver, copper, iron, tin, lead and bronze, i.e. substances having high specific gravity, malleability, opacity, and especially a peculiar lustre, the term "metal" became generic for all substances with these properties. In modern chemistry, however, the metals are a division of the elements, the members of which may or may not possess all these characteristics. The progress of science has, in fact, been accompanied by the discovery of some 70 elements, which may be arranged in order of their "metallic" properties as above indicated, and it is found that while the end members of the scale are most distinctly metallic (or non-metallic), certain central members, e.g. arsenic, may be placed in either division, their properties approximating to both metallic and non-metallic. One chemical differential utilizes the fact that metals always form at least one basic oxide which yields salts with acids, while non-metals usually form acidic oxides, i.e. oxides which yield acids with water. This definition, however, is highly artificial and objectionable on principle, because when we speak of metals we think, not of their chemical relations, but of a certain sum of mechanical and physical properties which unites them all into one natural family.

All metals, when exposed in an inert atmosphere to a sufficient temperature, assume the form of liquids, which all possess the following characteristic properties. They are (at least practically) non-transparent; they reflect light in a peculiar manner, producing what is called "metallic lustre." When kept in non-metallic vessels they take the shape of a convex meniscus. These liquids, when exposed to higher temperatures, soon contract or change others pass into vapours. When these vapours are like is not known in many cases, since, as a rule, they can be produced only at very high temperatures, precluding the use of transparent vessels. Silver vapour is blue, potassium vapour is green, many others (mercury vapour, for instance) are colourless. The liquid metals, when cooled down sufficiently, some at lower, others at higher, temperatures freeze into compact solids, endowed with (the relative and transitory) and the lustre of their liquids. These

frozen metals in general form compact masses consisting of aggregates of crystals belonging to the regular or rhombic or (more rarely) the quadratic system. Compared with non-metallic solids, they in general are good conductors of heat and of electricity. But their most characteristic, though not perhaps their most general, property is that they combine in themselves the apparently incompatible properties of elasticity and rigidity on the one hand and plasticity on the other. To this remarkable combination of properties more than to anything else the ordinary metals owe their wide application in the mechanical arts. In former times a high specific gravity used to be quoted as one of the characters of the genus; but this no longer holds, since we now know a series of metals lighter than water.

Non-Transparency.—This, in the case of even the solid metals, is perhaps only a very low degree of transparency. In regard to gold this has been proved to be so; gold leaf, or thin films of gold produced chemically on glass plates, transmit light with a green colour. On the other hand, infinitely thin films of silver which can be produced chemically on glass surfaces are absolutely opaque. Very thin films of liquid mercury, according to Melsens, transmit light with a violet-blue color; also thin films of copper are said to be translucent.

Colour.—Gold is yellow; copper is red; silver, tin, and some others are pure white; the majority are greyish.

Reflection of Light.—Polished metallic surfaces, like those of other solids, divide any incident ray into two parts, of which one is refracted while the other is reflected—with this difference, however, that the former is completely absorbed, and that the latter, in regard to polarization, is quite differently affected. The following values are due to Rubens and Hagen (Ann. der Phys., 1900, p. 352); they express the percentage of incident light reflected. The superiority of silver is obvious.

Crystalline Form and Structure.—Most (perhaps all) metals are capable of crystallization. The crystals belong to the following systems: regular system—silver, gold, palladium, mercury, copper, iron, lead; quadratic system—tin, potassium; rhombic system—antimony, bismuth, tellurium, zinc, magnesium. Perhaps all metals are crystalline, only the degree of visibility of the crystalline arrangement is very different in different metals, and even in the same metal varies according to the slowness of solidification and other circumstances.

Antimony, bismuth and zinc exhibit a very distinct crystalline structure, a bar-shaped ingot readily breaks, and the crystal faces are distinctly visible on the fracture. Tin also is crystalline; a thin bar, when bent, "creaks" audibly from the slipping of the crystal faces over one another; but the bar is not easily broken, although it is an apparently non-crystalline—Class I.

Gold, silver, copper, lead, aluminium, cadmium, iron (pure), nickel and cobalt are practically amorphous, the crystals (where they exist) being so closely packed as to produce a virtually homogeneous mass.—Class II.

The great contrast in apparent structure between cooled ingots of Class I. and of Class II. appears to be owing chiefly to the fact that, while the latter crystallize in the regular system, metals of Class I. form rhombic or quadratic crystals. Regular crystals crystallize in such ways that the face directions are such that and the surfaces diffuse differently in different directions. Hence, supposing the crystals immediately after their formation to be in absolute contact with one another all round, then, in the case of Class II., such contact will be maintained on cooling, while in the case of Class I. the contraction along a given straight line will in general have different values in any two neighbouring crystals, and the crystals consequently become slightly detached from one another. The crystalline structure which exists on both sides becomes visible only in the metals of the first class, and only there manifests itself in brittleness.
Closely related to the structure of metals is their degree of "plasticity" (susceptibility of being constrained into new forms without breach of continuity). This term of course includes as special cases the qualities of "malleability" (capability of being flattened out under the hammer) and "ductility" (capability of being drawn into wire); but these two special qualities do not always go parallel to each other, for this reason amongst others—that ductility in a higher degree than malleability is determined by the tenacity of a metal. Hence tin and lead, though very malleable, are little ductile. The quality of plasticity is developed to very different degrees in different metals, and even in the same species it depends on temperature, and may be modified by mechanical or physical operations.

A bar of zinc, for instance, as obtained by casting, is very brittle; but when heated to 100° or 150° C. it becomes sufficiently plastic to be rolled into the thinnest sheet or to be drawn into wire. Such sheet or wire then remains flexible after cooling, the originally only loosely cohering crystals having got intertwisted and forced into absolute contact with one another—an explanation supported by the fact that rolled zinc has a somewhat higher specific gravity (7-2) than the original ingot (6-9). The same metal, when heated to 205° C., becomes so brittle that it can be powdered in a mortar.

Pure iron, copper, silver and other metals are easily drawn into wire, and can be flattened into sheets or plates. But all these operations render the metals harder, and detach from their plasticity. Their original softness can be restored to them by "annealing," i.e. by heating them to redness and then quenching them. In the case of the silver, however, this applies only if the metal is perfectly pure. If it contains a few parts of carbon per thousand, the annealing process, instead of softening the metal, gives it a "temper," meaning a higher degree of hardness and brittleness (see below).

What we have called plasticity must not be confused with the notion of "softness," which means the degree of facility with which the plasticity of a metal can be discounted. Thus lead is far softer than silver, and yet the latter is by far the more plastic of the two. The famous experiments of H. E. Tresca show that the plasticity of certain metals at least goes considerably farther than had before been supposed.

He operated with lead, copper, silver, iron and some other metals. Round disks made of these metals were placed in a closily fitting cylindrical cavity drilled in a block of steel, the cavity having a circular aperture of two or four millimeters below. By an hydraulic press a pressure of 100,000 kilos was made to act upon the disks; when the metal was seen to "flow" out of the hole like a viscous liquid. In spite of the immense rearrangement of parts there was no break of continuity. What came out below was a compact cylinder with a roundish bottom, consisting of so many layers superimposed upon one another. Parallel experiments with layers of dough or sand plus some connecting material proved that the particles in all cases moved along the same tracks as would be followed by a flowing cylinder of liquid. Of metals, by the way, potassium and sodium are the softest; they can be kneaded between the fingers like wax. After these follow first bismuth and then lead, the latter being the softest of the metals used in the arts. Among these the softness decreases in about the following order: lead, pure silver, pure gold, tin, copper, aluminium, platinum, pure iron. As liquidity might be looked upon as the ne plus ultra of softness, this is the right place for stating that, while most metals, when heated up to their melting points, put up a tenacious resistance from the bottom up, the state, platinum and iron first assume, and throughout a long range of temperatures retain, a condition of viscous semi-solidity which enables two pieces of them to be "welded" together by pressure into intimate continuity.

According to Precht, the ordinary metals, in regard to the degree of facility or perfection with which they can be hammered flat on the anvil, rolled out into sheet, or drawn into wire, form the following descending series:

**Hammering.**

By the "hardness" of a metal we mean the resistance which it offers to the filer or engraver's tool. Taking it in this sense, it does not necessarily measure, e.g., the resistance of a metal to abrasion by friction. Thus, for instance, a leaden bronze is scratched by an ordinary steel knife-blade, yet the set of needles used for perforating postage stamps last longer if made of aluminium bronze than if made of steel.

**Elasticity.**—All metals are elastic to this extent that a change of form, brought about by stresses not exceeding certain limit values, will disappear on the stress being removed. Strains exceeding the "limit of elasticity" result in permanent deformation or (if sufficiently great) in rupture. Referring to the reader the article ELASTICITY, the reader can refer to the Standardization of Materials for the practical aspects of this subject, we give here a table of the "modulus of elasticity," E (column 2), for millimetre and kilogramme. Hence 1000/E is the elongation in millimetres per metre length per kilo. Column 3 shows the change causing a permanent elongation of 0-05 mm. per metre, which, for practical purposes, Wertheim takes as giving the limit of elasticity; column 4 gives the breaking strain. These values may vary within certain limits for different specimens.

**Specific Gravity.**—This varies in metals from 5-94 (lithium) to 22-48 (osmium), and in one and the same species is a function of temperature and of previous physical and mechanical treatment. It has in general one value for the powdery metal as obtained by reduction of the oxide in hydrogen below the melting point of the metal, another for the metal in the state in which it assumes spontaneously on freezing, and this latter value, in general, is modified by hammering, rolling, drawing, &c. These mechanical operations do not necessarily add to the density; stamping; it is true, does so necessarily, but rolling or drawing occasionally causes a diminution of the density. Thus, for instance, chemically pure iron in the ingot has the specific density 7-844; when it is rolled out into thin sheet, the value falls to 7-6; when drawn into thin wire, to 7-75. The following table gives the specific density of many metals. Where special statements are not made, the numbers hold for the ordinary temperature (15° to 17° or 20° C.,) referred to water of the same temperature as a standard, and to hold for the natural frozen metal.

For practical purposes the volatility of metals may be stated as follows:
1. Distillable below redness: mercury.
2. Distillable at red heat: cadmium, alkali metals, zinc, magnesium.
3. Volatilized more or less readily when heated beyond their fusing points in open crucibles: antimony (very readily), lead, bismuth, tin, silver.
5. Practically non-volatile: (copper), iron, nickel, cobalt, aluminium; also lithium, barium, strontium and calcium.

In the oxygenhydrogen flame silver boils, forming a blue vapour, while platinum volatilizes slowly, and osmium, though insufibulable, very readily.

Latent Heats of Liquefaction.—Of these we know little. The following numbers are due to Person—ice, it may be stated, being 80.

The latent heat of vaporization of mercury was found by Mariage to be 103 to 106.

Conductivity.—Conductivity, whether thermal or electric, is very differently developed in different metals; and, as an exact knowledge of these conductivities is of great importance, much attention has been given to their numerical determination (see CONDUCTION, ELECTRIC; and CONDUCTION OF HEAT).

The following table gives the electric conductivities of a number of metals as determined by Matthiesen, and the relative internal thermal conductivities of (nominally) the same metals as determined by Wiedemann and Franz, with rods about 5 mm. thick, of which one end was kept at 100°C, the rest of the rod in a "vacuum" (of 5 mm. tension) at 12°C. Matthiesen's results, except in the two cases noted, are from his memoir in Pogg. Ann., 1858, cii. 428.
Magnetic Properties.—Iron, nickel and cobalt are the only metals which are attracted by the magnet and can become magnets themselves. But in regard to their power of retaining their magnetism one on the other, it comes at all up to the compound metal steel. See MAGNETISM.

Chemical Changes.—Metals may unite chemically both with metals and with non-metals. The compounds formed in the first case, which may be either definite chemical compounds or solid solutions, are discussed under ALLOYS; in this place only combinations with non-metals are discussed, it being presumed that the free metal takes part in the reaction.

Metallic Substances Produced by the Union of Metals with Small Proportions of Non-Metallic Elements.

Hydrogen, as was shown by Graham, is capable of uniting with, or being occluded by certain metals, notably with palladium (p.), into metal-like compounds.

Oxygen.—Mercury and copper and some other metals are capable of dissolving their own oxides. Mercury, by doing so, is capable of uniting with oxygen and forming metallic compounds, which are stable and can exist in the ordinary atmosphere.

Arsenic combines readily with all metals into true arsenides, which latter, in general, are soluble in the metal itself. The presence in a metal of even small proportions of arsenide generally leads to considerable deterioration in mechanical qualities.

Phosphorus.—The remark just made might be said to hold for phosphorus also, since it is the same as if the metal contained arsenic in an alloy of copper with phosphorus (which is a compound), which possesses valuable properties. According to Abel, the most powerful effect is produced by from 1 to 1 1/2% of phosphorus. Such an alloy can be cast like a metal and is harder, more ductile, more malleable and more tenacious than iron, except in the latter hardness, elasticity, toughness and tensile strength.

Carbon.—Most metals when molten are capable of dissolving at least small proportions of carbon, which, in general, leads to deterioration in metallicity, except in the case of iron, by which the addition of small percentages of carbon gains in elasticity and tensile strength with little loss of plasticity (see IRON).

Silicon, so far as we know, behaves in most metals pretty much like carbon, but our knowledge of facts is limited. What is known is that cast iron is essentially an alloy of iron proper with 2 to 6% of carbon and more or less of silicon (see IRON). Alloys of copper and silicon are prepared by Deville in 1863. The alloy with 12% of silicon is white, hard and brittle. When diluted down to 4%-8%, it assumes the colour and fusibility of bronze, but, unlike it, is tenacious and ductile like iron.

Action of the More Ordinary Chemical Agents on the Simple Metals.

The metals to be referred to are always understood to be in the compact (frozen) condition, and that, wherever metals are enumerated as being similarly attacked, the degree of readiness in the action is indicated by the order in which the several members are named—the more readily attacked metal always standing first.

Water, at ordinary or slightly elevated temperatures, is decomposed more or less readily, with evolution of hydrogen gas and formation of a basic hydride, by (1) potassium (formation of KHO), sodium (NaH), lithium (LiOH), barium, strontium, calcium (BaH₂O₂, &c.); (2) magnesium, zinc, manganese (MgOH₂, &c.).

In the case of group 1 the action is more or less violent, and the hydroxides formed are soluble in water and very strongly basic; metals of group 2 are only slowly attacked, with formation of relatively feeble basic and alkaline solutions (from Na₂O). Among the more obvious, the metals not named so far may be said to be proof against the action of pure water in the absence of free oxygen (air).

By the joint action of water and air, thallium, lead, bismuth are only slowly attacked, with formation of more or less sparingly soluble hydroxides (ThHO, PbH₂O, BiH₂O₃), which, in the presence of carbonic acid, pass into still less soluble basic carbonates. Iron, when exposed to moisture and air, "rusts"; but this process never takes place in the absence of air, and it is questionable whether it ever sets in in the absence of carbonic acid (see RUST).

Copper, in the present connection, is intermediate between iron and the following group of metals.

Mercury, if pure, and all the "noble" metals (silver, gold, platinum, platinum-platinum) are absolutely proof against water even in the presence of oxygen and carbonic acid.

The metals grouped together above, under 1 and 2, act on steam pretty much as they do on liquid water, but more so; the following are less so, in proportion as the steam is condensed.

Aqueous Sulphurous or Hydrochloric Acid readily dissolves groups 1 and 2, with evolution of hydrogen and formation of chlorides or sulphates. The same holds for the following groups of metals, except for magnesium; magnesium is as insoluble in hydrochloric acid as in water; the same holds true for the acid. Tin dissolves readily in strong hot hydrochloric acid as SnCl₂; aqueous sulphurous acid does not act on it appreciably in the cold; at 150° it attacks it more or less completely, dissolving it in all length and breadth. When the acid is stronger, of sulphuric acid and the gas and deposition of sulphur (Calvert and Johnson). A group (B), comprising copper, is, substantially, attacked only in the presence of oxygen.

Lead, in its unprotected state, or as its oxide if not too hot, remains unchanged. A group (C) may be formed of mercury, silver, gold and platinum, which are not touched by either of these acids in the circumstances named.

The concentrated sulphuric acid does not attack gold, platinum and platinum-platinum generally; all other metals (including silver) are converted into sulphates, with evolution of sulphur dioxide. In the case of iron, ferric sulphate Fe₂(SO₄)₃ is produced; tin yields a reaction with insalubrity of its oxygen, which is stronger, of sulphuric acid and deposition of sulphur (Calvert and Johnson). A group (B), comprising copper, is, substantially, attacked only in the presence of oxygen.

Iron, in its unprotected state, or as its oxide if not too hot, remains unchanged. A group (C) may be formed of mercury, silver, gold and platinum, which are not touched by either of these acids in the circumstances named.

Aqueous Nitric Acid (Aqueous) —Gold, platinum, iridium and rhodium only are proof against the action of this powerful oxidizer. Tin and antimony (also arsenic) are readily attacked by nitric acid, and the hydrated oxide of the highest oxides of SnO₂, Sb₂O₃ (As₂O₃) —the oxides of tin and antimony being insoluble in water and in the acid itself. All other metals, including palladium, are dissolved as nitrates, the oxidizing part of the reagent being generally reduced to nitrous acid, while the stronger the reaction is, the more strongly the metal is attacked. Nitric acid, under certain conditions, reduces the dillute acid, partially, at least, to nitrous oxide, NO₂ or ammonium nitrate, NH₄NO₃.

Aqua Regia, a mixture of nitric and hydrochloric acids, converts all metals to chlorides (even gold, the "king of metals," whence the name) into chlorides, except only rhodium, iridium and ruthenium which, when pure, are not attacked.

Carbonic Acid.—Carbonic Acid does not decomposing liquid pure water, only a few dissolve in aqueous caustic potash or soda, with evolution of hydrogen.

The most important of these are aluminium and zinc, which are converted into aluminate, Al(OH)₃, and zinicate, Zn(OH)₂, respectively. But of the rest the most common, when used with boiling sufficiently strong alkali, are attacked at least superficially; of ordinary metals only gold, platinum, and silver are perfectly proof against the reagents under consideration, and these accordingly form the upper limits of the vessels used for analytical operations involving the use of aqueous caustic alkalis. For commercial purposes iron is universally employed, and works well; but it is not available analytically, because a supercritical oxidation of the metal takes place when the water is boiled up (the heat of the vessel), and the dissolved oxygen cannot be prevented. Basins made of pure malleable nickel are free from this drawback; they work as well as platinum, and rather better than silver ones do. There is hardly a single metal which holds out against the alkalis themselves when in the state of storage or even the most violently attacked. In chemical laboratories fusions with caustic alkalis are always affected in vessels made of gold or silver, these metals holding out fairly well even in vessels made of all the other metals, which are not attacked as well against aqueous alkalis, is most violently attacked by the fused reagents. Yet tons of caustic soda are fused daily in chemical works in iron pots without thereby suffering corrosion, which seems to show that (cleanliness of the gold and silver, is attributed only by the fused alkali and air, the influence of the latter being of course minimized in large-scale operations.

Oxygen or Air.—The noble metals (from silver upwards) do not combine directly with oxygen given as oxygen gas (O₂), although, like silver, they may absorb this gas largely when in the fused condition, and may not be proof against ozone, O₃. Mercury, within
METALLOGRAPHY

Of a certain range of temperatures situated close to its boiling point, combines slowly with oxygen into the red oxide, which, however, breaks up again at higher temperatures. All other metals, when heated in oxygen or air, are converted, or more readily, into stable oxides. Potassium, for example, yields peroxides, K₂O₂ or K₂O₃; lithium gives Na₂O; the barium-group metals, as well as magnesium, cadmium, zinc, lead, copper, are converted into their monoxides MeO. Bismuth and antimony give (the latter very readily) selenium and sulfur, the latter being derived from the latter by passing a single oxides. Aluminium, when pure and kept out of contact with siliceous matter, is only oxidized at a white heat, and then very slowly, to alumina, Al₂O₃. Tin, at high temperatures, passes slowly into oxide, SnO₂.

Sodium—Among the better known metals, gold and aluminium are the only ones which, when heated with sulphur or in sulphur vapour remain unchanged. All the rest, under these circumstances, are converted into sulphides. The metals of the alkalis and alkaline earths, however, yield a sulphide with a metallic luster, and in this manner, burn in sulphur vapour as they do in oxygen. Of the heavy metals, copper is the one which exhibits by far the greatest avidity for sulphur, its sub sulphide CuS being the stablest of all heavy metallic sulphides in opposition to dry reactions.

Chlorine.—All metals, when treated with chlorine gas at the proper temperatures, pass into chlorides. In some cases the chlorine is taken up in two instamles, a lower chloride being produced first, to pass ultimately into a higher chloride. Iron, for instance, is converted into FeCl₂ and then ultimately into FeCl₃, which means a mixture of the two chlorides, or pure FeCl₃ as a final product. Of the several products, the chlorides of gold and platinum (AuCl₃ and PtCl₄) are the only ones which when heated beyond their temperatures of volatilization but dissociate into free chlorine and an intimate chlorination product of copper, CuCl₂, which, when heated to redness, decomposes into the lower chloride, CuCl, and chlorine. All the rest, when heated by themselves, volatilize, some at lower, others at higher temperatures. Of the several individual chlorides, the following are liquids or solids, volatile enough to be distilled from glass vessels: AsCl₃, SbCl₅, SnCl₄, BiCl₃, HgCl₂, the chlorides of arsenic, antimony, tin, bismuth, mercury respectively. The following are readily volatilized in a current of chlorine, at a red heat: AlCl₃, CrCl₃, FeCl₃, the chlorides of aluminium, chromium, iron. The following, though volatile at higher temperatures, are not volatilized at full redness: KCl, NaCl, LiCl, CaCl₂, MgCl₂, MnCl₂, ZnCl₂, MnCl₃, PbCl₂, PbCl₃, AgCl, AlCl₃, the chlorides of alkali and alkaline earth metals, cadmium, zinc, magnesium, lead, silver. Somewhat less volatile than the last named group are the chlorides (MCl₃) of barium, strontium and calcium.

Volatilic chlorides, as a class, are readily soluble in water. The following are the most important exceptions: silver chloride, AgCl, and mercuric chloride, HgCl₂, are absolutely insoluble; lead chloride, PbCl₂, and cuprous chloride, CuCl₂, are very sparingly soluble in water. Gold chloride, AuCl₃, is readily dissolved by (liquid) water, with formation of oxide (Au₂O₃) or oxochlorides (Sb₂O₅, BiCl₃) and hydrochloric acid. The chlorides MgCl₂, AlCl₃, CrCl₃, FeCl₃, suffer a similar decomposition when evaporated with water, and are also soluble in water. The chlorides CuCl₂, NiCl₂, and even CaCl₂. All chlorides, except those of silver and mercury (and, of course, those of gold and platinum), are oxidized by steam at high temperatures, with elimination of hydrochloric acid.

For the characters of metals as chemical elements see the special articles on the different metals.

See generally A. Rossing Geschichte der Metalle. (1901); B. Neumann, Die Metalle (1904); also treatises on chemistry.

METALLOGRAPHY.—The examination of metals and alloys by the aid of the microscope has assumed much importance in recent years. Several observers have been of the opinion that it can be considered to be a natural development of the use of the microscope in determining the constitution of rocks, a study to which the name petrography has been given. It would appear, however, that it is an extension of the study of the structure of meteoric irons. There can be no question that in the main it was originated by Dr H. C. Sorby, who in 1864 gave the British Association an account of his work. Following the work of Sorby came that of Professor A. Märens of Charlottenburg, presenting many features of originality. F. Osmond has obtained results in connexion with iron and steel which are of the highest interest. A list of the more important papers by these and other workers will be found in the appended bibliography.

Preparation of the Specimen.—Experience alone can enable the operator to determine what portion of a mass of metal or alloy will afford a trustworthy sample of the whole. In studying a series of binary alloys it has been found advantageous in certain cases to obtain one section which will show in a general way the variation in structure from one end of the series to the other.

This has been effected by pouring the lighter constituent carefully on the surface of the heavier constituent, and allowing solidification to take place. A section through the colut so obtained will show a gradation in structure from pure metal on one side to pure metal on the other. A thin slice of metal is usually cut by means of a hack-saw driven by mechanism. The thickness of the piece should not be less than ⅛ in. and in order that it may be firmly held between the fingers it should not be less than ⅛ in. square. The preliminary stages of polishing are effected by emery paper placed preferably on wooden disks capable of being revolved at a high rate of speed. The finest grade of emery paper that can be obtained is used towards the end of the operation. Before use the finer papers should be rubbed with a hard steel surface to remove any coarse particles. The completion of the operation of polishing is generally effected on wet cloth or parchment covered with a small amount of carefully washed jeweller's rouge. Various mechanical appliances are employed to minimize the labour and time required for the polishing. These usually consist of a series of interchangeable revolving disks, each of which is covered with emery paper, cloth or parchment, according to the particular stage of polishing for which it is required. In the case of brittle alloys and of alloys having a very soft constituent, which during polishing tends to spread over and obliterate the harder constituents, polishing is in many cases altogether avoided by casting the alloy on the surface of glass or mica. In this way, with a little care, a perfect surface is obtained, and it is only necessary to develop the structure by suitable etching. In adopting this method, however, instances have occurred in which the removal of the cast surface has shown a structure differing considerably from the original.

Polishing in Bas-Relief.—If the polishing be completed with fine rouge on a sheet of wet parchment, placed upon a comparatively soft base such as a piece of deal, certain soft constituents of an alloy may often be eroded in such a manner as to leave the hardest portions in relief. For the later stages of polishing H. L. Le Chatelier recommends the use of alumina obtained by the calcination of ammonium alum; and for the final polish of soft metals, chromium oxide.

Although in some cases a pattern becomes visible after polishing, yet more frequently a mirror-like surface is produced in which no pattern can be detected, or if there is a pattern it is blurred, as if seen through a veil or mist. This is due to a thin layer of metal which has been dragged, or smeared, uniformly over the whole surface by the friction of the polishing process. Such a surface layer is formed in all cases of polishing, and the peculiar lustre of burnished silver or steel is probably due to this layer. But to the metallographist it is an inconvenience, as it conceals scratches left by imperfect polishing, and also hides the pattern. It is therefore desirable to conduct the polishing so as to make this layer as thin as possible: it is claimed for alumina that it can be so used as to produce a much thinner surface layer than that due to the employment of rouge. The surface layer is very readily removed by appropriate liquid reagents, and, of course, the action of the etching reagent acts differently on the individual substances in the alloy and the pattern can thus be emphasized to any required extent. Osmond divides etching reagents into three classes—acids, halogens and salts. As regards acids, water containing from 2 to 10% of hydrochloric acid is useful. It is made by mixing 10 grams of potassium bichromate with 10 grams of sulphuric acid in 100 grams of water. The use of nitric acid requires much experience. It is frequently employed in the examination of steels, Sir W. C. Roberts-Austen preferred a 1% solution in alcohol, but many workers use concentrated acid, and effect the etching by allowing a stream of water to dilute the film of acid left on the surface of the specimen after dipping it. Of the halogens, iodine is the most useful. A solution in alcohol is applied, so that a single drop covers half a square inch of surface. The specimen is then washed with alcohol, and dried with a piece of fine linen or chamois leather. Tincture of iodine also affords a means of identifying lead in certain alloys by the formation of a yellow iodide of lead, while the vapour of iodine has in certain cases been
used to tint the constituents. Thin coloured films may often be produced by the oxidation of the specimen when heated in air. This, as a means of developing the structure, in the case of the copper alloys is specially useful. Tinted crystals may thus be distinguished from the investing layer caused by the presence of a minute quantity of another constituent. The temper colours produced by heating iron or steel in air are well known. Carbide of iron is less oxidizable than the iron with which it is intimately associated, and it assumes a brown tint, while the iron has reached the blue stage. These coloured films may be fixed by covering with thin films of gelatine.

In some cases the alloy may be attacked electrolytically by exposing it for a few minutes to a weak electric current in a bath of very dilute sulphuric acid. Certain organic bodies give very satisfactory results. The Japanese, for instance, produce most remarkable effects by simple reagents of which an infusion of certain forms of grass is a not unimportant constituent. In the case of iron and steel a freshly prepared infusion of liqueur root has been found to be most useful for colouring certain constituents of steel. Osmond, who was the first to use this reagent, insisted that it should be freshly prepared and always used under identical conditions as regards age and concentration. His method of applying it was to rub the specimen on parchment moistened with it, but he has subsequently modified this 'polish attack' by substituting a 2% solution of ammonium nitrate for the liqueur infusion. In each case a small quantity of freshly precipitated calcium sulphate is used on the parchment to assist the polishing.

**Appliances used in Micrography.**—The method of using the microscope in connexion with a camera for photographic purposes will now be considered. Every micrographer has his own views as to the form of an installation to be adopted, and it will therefore be well to give an illustration of a definite apparatus which has been found to give satisfactory results. It consists of a microscope A with a firm base placed in a horizontal position. The microscope can be connected by a tube, B with the expanded camera CC, at the end of which is the usual frame to receive the photographic plate. A practised observer can focus on a plate of clear glass by the aid of a subsidiary low-power microscope lens. If a semi-transparent plate is employed it should be as fine as possible. The surface of the table is cut in such a way near H that the observer who is seated may conveniently examine the object on the stage of the microscope, the portion of it being aside for this purpose. The substage focusing is effected by a rod, PFF, and geared attached to the fine adjustment of the microscope GA; flap J when raised forms the support of the lamp used for illumination. As an illuminant an arc light has many advantages, as the exposure of the plate used will seldom exceed 10 seconds. The filament of a Nernst lamp can be used as the source of light; though not so brilliant as the arc it possesses the great advantage of perfect immobility. For the best results, especially with high powers, the source of light must be small, so that its image can be focussed on to the surface of the object; this advantage is possessed by both of these illuminants. Next in value comes the acetylene flame, and an incandescent lamp or a gas lamp with a mantle will give good results, but with much longer exposure. Actual illumination is best effected by a Beck vertical illuminator or a Zeiss prism. It is necessary that the lens used for concentrating the light on the illuminator should be an achromatic one, as colour effects cause trouble in photographing the objects. For lower powers the Lieberkühn parabolic illuminator is useful. Certain groups of alloys show better under oblique illumination, which may be effected by the aid of a good condensing lens, the angle of incidence being limited by the distance of the object from the objective in the case of high magnification. As regards objectives, the most useful are the Zeiss 2 mm., 4 mm. and 24 mm.; two other useful objectives for low powers being 35 mm. and 70 mm., both of which are projecting objectives. A projecting eye-piece, preferably of low power, should be employed with all but the two latter objectives. The immersion lens, the Zeiss 2 mm., is used with specially thickened cedar oil, and if the distance from the objective to the plate is 7 feet, magnifications of over 2000 diameters can easily be obtained. As regards sensitized plates, excellent results have been obtained with Lumière plates sensitive to yellow and green. The various brands of "process" plates are very serviceable where the contrasts on the specimen are not great. Some reproductions of photo-micrographs of metals and alloys will be found in the plate accompanying the article **Alloys**.

**METALLURGY, the art of extracting metals from their ores; the term being customarily restricted to commercial as opposed to laboratory methods. It is convenient to treat electrical processes of extraction as forming the subjects of Electrochemistry and Electrometallurgy (qq.v.). The following table enumerates in the order of their importance the metals which our subject at present is understood to include; the second column gives the chemical characters of the ores utilized, italics indicating those of subordinate importance. The term "oxide" includes carbonate, hydrate, and, when marked with *, silicate.**

**Metal, Character of Ores.**

- Metal, Character of Ores.  
- Mercury, Sulphide, reguline metal.  
- Antimony, Sulphide.  
- Bismuth, Reguline metal.  
- Nickel and cobalt, Iron, arsenides, silicates.  
- Platinum, iridium, &c., Reguline.  

**General Sequence of Operations**

Occasionally, but rarely, metallic ores occur as practically pure compact masses, from which the accompanying matrix or "gangue" can be detached by hand and hammer. In most cases the "ore" (see Mineral Deposits; Veins), as it comes out of the mine or quarry, is simply a mixture of ore proper and gangue, in which the latter not infrequently predominates. Hence it is generally necessary to purify the ore before the liberation of the metal is attempted.

Most metallic ores are specifically heavier than the accompanying impurities and their purification is generally effected by reducing the crude ore to a fine enough powder to detach the metallic from the earthy part, and then washing away the latter by a current of water.

The majority of ores being chemical compounds, the extraction of their metals demands chemical treatment. The chemical operations involved may be classified as follows—

1. **Fiery Operations.**—The ore, generally with some "flux," is exposed to the action of fire. The fire in most cases has a chemical, in addition to its physical, function. Moreover the furnace is designed so as to facilitate the action of the heat and furnace gases in the desired direction. It is intended either to burn away certain components of the ore—in which case it must be so regulated as to contain a sufficient excess of unburned oxygen; or it is meant to deoxidize ("reduce") the ore, when the draught must be restricted so as to keep the ore constantly wrapped up in combustible flame gases (carbon monoxide, hydrogen, marsh-gas, &c.). The majority of the chemical operations of metallurgy fall into this category, and those processes other metal-reducing agents than those naturally contained in the fire (or blast) are only exceptionally employed.

2. **Amalgamation.**—The ore by itself (if it is a reguline one), or with certain reagents (if it is not), is worked up with mercury so that the metal is obtained as an amalgam, which can be separated mechanically from the dross. The purified amalgam is distilled, when the mercury is recovered as a distillate while the metal remains.

3. **Wet Processes.**—Strictly speaking, certain amalgamation methods fall under this head; but, in its ordinary acceptance, the term refers to processes in which the metal is extracted either from the natural ore, or from the ore after roasting or other preliminary treatment, by an acid or salt solution, and from this solution precipitated—generally in the reguline form—by some suitable agent.

**Fog methods** of metal extraction at once yield a pure product. What as a rule is obtained is a more or less impure metal, which requires to be "refined" to become fit for the market.

**Chemical Operations.**—Amalgamation and wet-way processes have limited applications, being practically confined to copper, gold and silver. We therefore here confine ourselves, in the main, to pyro-chemical operations.

The method to be adopted for the extraction of a metal from its ore is determined chiefly, though not entirely, by the nature of the non-metallic component with which the metal is combined. The simplest case is that of the reguline ores where there is no non-metallic component and the metal is combined with carbon.

**Oxides, Hydrates, Carbonates and Silicates.**—All iron and tin ores proper fall under this heading, which, besides, comprises certain ores of copper, of lead and of zinc. The first step consists in subjecting the crude ore to a roasting or calcining process, the object of which is to remove the water and carbon dioxide, and burn away, to some extent at least, the sulphur, arsenic or organic matter. The residue consists of an impure oxide of the respective metal, which in all cases is further refined by a process of fusion with a flux, the nature of which is such that the metal be present as a silicate, lime must be added in the smelting to remove the silica and liberate the oxide.

The temperature required for the reduction of zinc lodes above the blende point, in both the metal and the steel, is about 200 degrees Centigrade. In the case of ore and reducing agent (charcoal is generally used) must be heated in a retort combined with condensing apparatus. In all the other cases the reduction is effected in the fire itself, a tower-shaped blast furnace being preferably used, as the furnace is charged with alternate layers of fuel and ore (or rather ore and flux, see below), and the whole kindled from below. The metallic oxide, partly by the direct action of the carbon with which it is in contact, but principally by that of the carbon monoxide produced in the lower strata from the oxygen of the blast and the hot carbon there, is reduced to the metallic state; those processes of reduction or the uses and running the slag upon the furnace, whence both are withdrawn by opening plug-holes.

**Sulphides.**—Iron, copper, lead, zinc, mercury, silver and antimony very frequently present themselves in this state of combination, as a more or less intimate compound, in a family of natural minerals, of which two principal classes: (1) such as substantially consist of simple sulphides, as iron pyrites (FeS), galena (PbS), blende (ZnS), cinnabar (HgS); and (2) complex sulphides, such as various kinds of sulphureous arsenides, antimonides, etc., and compounds of iron, zinc, copper, nickel, cobalt, and silver; and mixtures of these and other sulphides with one another.

In treating a sulphureous ore, the first step as a rule is to subject it to oxidation by roasting it in a reverberatory or other furnace, which leads to the burning away of at least part of the arsenic and part of the sulphur. The effect on the several individual metallic sulphides (supposing only one of these to be present) is as follows:—

1. Those of silver (AgS) and mercury (HgS) yield sulphur dioxide gas and metal; in the case of silver, sulphate is formed at low temperatures. Metallic mercury, in the circumstances, goes off as a vapour, which is collected and condensed; silver remains as a regulus, but pure sulphide of silver is hardly ever worked.

2. Sulphides of iron, such as FeO, FeS and ZnO as final products, some basic sulphate being formed at the earlier stages, especially in the case of zinc. The oxides can be reduced by carbon.

3. The sulphides of lead and copper yield, the former a mixture of lead sulphate and metal, the latter a basic sulphate. Sulphate of lead is stable at a red heat; sulphate of copper breaks up into oxide, sulphide and oxide. In practice, neither oxidation process is ever pushed to the end; it is stopped when enough of the useful product is obtained. The oxide contains oxygen and sulphur in the ratio of O:S. The access of air is then stopped and the whole heated to a higher temperature, when the whole of the sulphur and oxygen is eliminated. This process is known as the roasting or calcining of the metal.

4. Sulphide of antimony, when roasted in air, is converted into a kind of alloy of sulphide and oxide; the same holds for iron, only less so. Silver is quite unaltered by roasting. Sooty carbon added together with metallic iron in the proportion of 2Fe:1PbS yields a regulus (=1Pb) and a "mat" ZnO, which, however, on cooling, decomposes into the ordinary sulphide FeS and finely divided iron. Sooty carbon has been used for the recovery of silver in the general metallurgical proposition: Any one of the metals, copper, iron, tin, lead, silver, antimony, arsenic, in general, is capable of desulphurizing (at least partially) any one of the others that follow it in the series just given, and it does so the more readily and completely the greater the number of intervening terms. Hence, supposing a complete mixture of these metals to be melted down under circumstances admitting of only a partial sulphurization of the whole, the result will be the best chance of passing into the "mat," while the arsenic is the first to be eliminated as such, or, in the presence of oxidants, as oxide.

**Arsenides.**—Although arsenides are amongst the commonest individual ores of metals generally, ores consisting essentially of arsenides are comparatively rare. The most important are certain double arsenides of cobalt and nickel, which in practice are always contaminated with the arsenides or other compounds of foreign metals, such as iron, nickel, cobalt, manga, manganese, nickel, and so on. The general arsenic of these ores is as follows: The ore is first roasted by itself, when a part of the arsenic goes off as such and as oxide, while a complex of lower arsenides remains. This residue is now subjected to careful oxidizing, (for the arsenic of the arsenides) and then subjected to reduction, the slag as a "speiss." (This term has the same meaning in reference to arsenides as "mat" has in regard to sulphides.) By stopping the process at the right moment, we can produce a speiss which contains all the cobalt, nickel, and iron as well as silver, and if the process is renewed we can further produce a speiss which contains only nickel and a slag which substantially is one of cobalt only. The composition of the speisses generally varies from AsMe to AsMe, where Me represents one atomic weight of metal in tate, so that in general 

\[ Me = Fe + Co + Ni, \]  

the silicious
METAL-WORK

It should be possible to represent each quality of a metal as a function of $x$, n/m, and of the nature of the individual bases that make up the MO and (Fe or Al) O respectively. Our actual knowledge is far short of this possibility. The problem, in fact, is very difficult, the more so as it is complicated by the existence of aluminates, compounds such as Al$_2$O$_3$·3CaO, in which aluminium plays the part of acid, and the occasional existence of compounds of fluorides of such metals. The formation of Slags, or, in fact, comes to the same thing, of metallic silicates, was especially studied by Percy, Smith, Bischof, Plattner and others, and in more recent times by Vogt, Doelter, and at the Geophysical laboratory of the Carnegie Institution, Washington.

METAL-WORK. Among the many stages in the development of primate man, none can have been of greater moment in his struggle for existence than the discovery of the metals, and the means of working them. The names generally given to the three prehistoric periods of man's life on the earth—the Stone, the Bronze and the Iron age—imply the vast importance of the progressive steps from the flint knife to the bronze belt, and last to the keen-edged elastic iron weapon or tool.

The metals chiefly used in the arts have been gold, silver, copper and tin (the last two generally mixed, forming an alloy called bronze), iron and lead (see the separate articles on these metals). Their peculiarities have naturally marked out each of them for special uses and methods of treatment. The durability and the extraordinary ductility and pliancy of gold, its power of being subdivided, drawn out or flattened into wire or leaf of almost infinite fineness, has led to its being used for works where greater malleability and delicacy are of utmost importance; it is used, for the most part, for objects of adornment and luxury, as distinct from those of utility.

In a lesser degree most of the qualities of gold are shared by silver, and consequently the treatment of these two metals has always been very different, though the greater abundance of the latter metal has allowed it to be used on a larger scale and for a greater variety of purposes. The great fluidity of bronze when melted, the slightness of its contraction on solidifying, together with its density and hardness, make it especially suitable for casting, and allow of its taking the impress of the mould with extreme sharpness and delicacy. In the form of plate it can be tempered and annealed till its elasticity and toughness are much increased, and it can then be formed into almost any shape under the hammer and punch. By other methods of treatment, known to the ancient Egyptians, Greeks and others, but now forgotten, it could be hardened and formed into knife and razor edges of the utmost keenness. In many specimens of modern brass, small quantities of silver, lead and zinc have been found, but their presence is probably accidental. In modern times brass has been much used, chiefly for the sake of its cheapness as compared with bronze.

In beauty, durability and delicacy of surface it is very inferior to bronze, and, though of some commercial importance, has been of but little use in the production of works of art. To some extent copper was used in an almost pure state during medieval times, especially from the 12th to the 15th century, mainly for objects of ecclesiastical use, such as pyxes, monstrances, reliquaries and crosiers, partly on account of its softness under the tool, and also because it was slightly easier to apply enamel and gilding to pure copper than to bronze (see fig. 1). In the medieval period it was used to some extent in the shape of thin sheeting for roofs, as at St Mark's, Venice; while during the 16th and 17th centuries it was largely employed for ornamental domestic vessels of various sorts.
**METAL-WORK**

**Iron.**—The abundance in which iron is found in so many places, its great strength, its remarkable ductility and malleability in a red-hot state, and the ease with which two heated surfaces of iron can be welded together under the hammer combine to make it specially suitable for works on a large scale where strength with lightness are required—things such as screens, window-grills, ornamental hinges and the like. In its hot plastic state iron can be formed and modelled under the hammer to almost any degree of refinement, while its great strength allows it to be beaten out into leaves and ornaments of almost paper-like thinness and delicacy. With repeated hammering, drawing out and annealing, it gains much in strength and toughness, and the addition of a very minute quantity of carbon converts it into steel, less tough, but of the keenest hardness. The large employment of cast iron is comparatively modern, in England at least only dating from the 16th century; it is not, however, incapable of artistic treatment if due regard be paid to the necessities of casting, and if no attempt is made to imitate the fine-drawn lightness to which wrought iron so readily lends itself. At the best, however, it is not generally suited for the finest work, as the great contraction of iron in passing from the fluid to the solid state renders the cast somewhat blunt and spiritless.

Among the Assyrians, Egyptians and Greeks the use of iron, either cast or wrought, was very limited, bronze being the favourite metal, almost for all purposes. The difficulty of holding the iron was probably one reason for this, as well as the now forgotten skill which enabled bronze to be tempered to a steel-like edge. It had, however, its value, of which a proof occurs in Homer (II. xxiii.), where a mass of iron is mentioned as being one of the prizes at the funeral games of Patroclus.

Methods of Manipulation in Metal-Work.—Gold, silver and bronze may be treated in various ways, the chief of which are (1) casting in a mould, and (2) treatment by hammering and punching (Fr. repoussé).

The first of these, casting is chiefly adapted for bronze, or iron. Analyses of the iron of prehistoric weapons have brought to light the interesting fact that many of the earliest specimens of iron manufacture contain a considerable percentage of nickel. This special alloy does not occur in any known iron ores, but is invariably found in meteoric iron. It thus appears that iron was manufactured from meteoric iron which had fallen to the earth in an almost pure metallic state, possibly long before prehistoric man had learnt how to dig for and smelt iron in any of the forms of ore which are found on this planet.

In the case of the more precious metals only if they are used on a very small scale. The reason of this is that a repoussé relief is of much thinner substance than if the same design were cast, even by the most skilful metal-worker, and so a large surface may be produced with a very small expenditure of valuable metal. Casting is probably the primitive method of metal-work. This has passed through three stages, the first being represented by solid castings, such as are most celebrated and other implements of the prehistoric time; the mould was formed of clay, sand or stone, and the fluid metal was poured in till the hollow was full. The next stage was, in the case of bronze, to introduce an iron core, probably to save needless expenditure of the more valuable metal. The British Museum possesses an interesting Etruscan or Archaic Italian example of this primitive device. It is a bronze statuette from Sessa on the Volturno, about 2 ft. high, of a female standing, robed in a close-fitting chiton. The presence of the iron core has been made visible by the splitting of the figure, owing to the unequal contraction of the two metals. The forearms, which are extended, have been cast separately and soldered or brazed on to the elbows. The third and last stage in the progress of the art of casting was the employment of a core, generally of clay, round which the metal was cast in a mere skin, only thick enough for strength, without waste of metal. The Greeks and Romans attained to the greatest possible skill in this process. Their exact method is not certainly known, but it appears probable that they were acquainted with the process now called à cire perdue—the same as that employed by the great Italian artists in bronze. Cellini, the great Florentine artist of the 16th century, has described it fully in his *Trattato della Scultura*. If a statue was to be cast, the figure was first roughly modelled in clay—only rather smaller in all its dimensions than the future bronze; all over this a skin of wax was laid, and worked by the sculptor with modelling tools to the required form and finish. A mixture of pounded brick, clay and ashes was then ground finely in water to the consistence of cream, and successive coats of this mixture were then applied with a brush, till a second skin was formed all over the wax, fitting closely into every line and depression of the modelling. Soft clay was then carefully laid on to strengthen the mould, in considerable thickness, till the whole statue appeared like a shapeless mass of clay, round which iron hoops were bound to hold it all together. The whole was then thoroughly dried, and placed in a hot oven, which baked the clay, both of the core and the outside mould, and melted the wax, which was allowed to run out from small holes made for the purpose. Thus a hollow was left, corresponding to the skin of wax between the core and the mould, the relative positions of which were preserved by various small rods of bronze, which had previously been driven through from the outer mould to the rough core. The mould was now ready, and melted bronze was poured in till the whole space between the core and the outer mould was full. After slowly cooling, the outer mould was broken away from outside the statue and the inner core as much as possible, broken away from the statue through a hole in the foot or some other part of the statue. The projecting rods of bronze were then cut away, and the whole finished by rubbing down and polishing over any roughness or defective places. The most skilful sculptors, however, had but little of this after-touching to do, the final modelling and even polish which they had put upon the wax being faithfully reproduced in the bronze casting. The further enrichment of the object by enamels and inlay of other metals was practised at a very early period by Assyrian, Egyptian and Greek metal-workers, as well as by the artists of Persia and medieval Europe.

The second chief process, that of hammered work (Gr. σφράγισμα; Fr. repoussé), was probably adopted for bronze-work on a large scale before the art of forming large castings was discovered. In the most primitive method thin plates of bronze were hammered over a wooden core, rudely cut into the required shape, the core serving the double purpose of giving shape to and strengthening the thin metal. A further development in the art of hammered work consisted in laying the metal plate on a soft
and elastic bed of cement made of pitch and pounded brick. The design was then beaten into relief from the back with hammers and punches, the pitch bed yielding to the protuberances which were thus formed, and serving to prevent the punch from breaking the metal into holes. The pitch was then melted away from the front of the embossed relief, and applied in a similar way to the back, so that the modelling could be completed on the face of the relief, the final touches being given by the graver. This process was chiefly applied by medieval artists to the precious metals, but by the Assyrians, Greeks and other early nations it was largely used for bronze. The great gates of Shalmaneser II., 858-823 B.C., from Balawat, now in the British Museum, are a remarkable example of this sort of work on a large scale, though in the neighbourhood of the celebrated tin and copper mines, which have been worked from a very early period. The use of lead has been more extended. In sheets it forms the best of all coverings for roofs and even spires. In the Roman and medieval periods it was largely used for coffins, which were often richly ornamented with cast work in relief. Though fusible at a very low temperature, and very soft, it has great power of resisting decay from damp or exposure. Its most important use in an artistic form has been in the shape of baptismal fonts, chiefly between the 11th and the 14th centuries. The superior beauty of colour and durability of old specimens of lead is owing to the natural presence of a small proportion of silver. Modern smelters carefully extract this silver from the lead ore, thereby greatly impairing the durability and beauty of the metal.

As in almost all the arts, the ancient Egyptians excelled in their metal-work, especially in the use of bronze and the precious metals. These were worked by casting and hammering, and ornamented by inlay, gilding and enamels with the greatest possible skill. From Egypt perhaps was derived the early skill of the Hebrews. Further instruction in the art of metal-working came probably to the Jews from the neighbouring country of Tyre. The description of the great gold lions of Solomon’s throne, and the laver of cast bronze supported on figures of oxen, shows that the artificers of that time had overcome the difficulties of metal-working and founding on a large scale. The Assyrians were perhaps the most remarkable of all ancient nations for the colossal size and splendour of their works in metal; whole circuit walls of great cities, such as Ecbatana, are said to have been covered with metal plates, gilt or silvered. Herodotus, Athenaeus and other Greek and Roman writers have recorded the enormous number of colossal statues and other works of art for which Babylon and Nineveh were so famed. The numerous objects of bronze and other metals brought to light by the excavations in the Tigris and Euphrates valleys, though mostly on a small scale, bear witness to the great skill and artistic power of the people who produced them; while the discovery of some bronze statuettes, shown by inscriptions on them to be not later than 2200 B.C., proves how early was the development of this branch of art among the people of Assyria.

The Metal-Work of Greece.—The early history of metal-working in Greece is extremely obscure, and archaeologists are divided in opinion even on so important a question as the relative use of bronze and iron in the Homeric age. The evidence of Mycenaean remains, as compared with the literary evidence of Homer, is both inadequate and inconclusive (see Aegean Civilization; Greek Art; Arms and Armour, Ancient; Plate; &c.). The poems of Homer are full of descriptions of elaborate works in bronze, gold and silver, which, even when full allowance is made for poetic fancy, show clearly enough very advanced skill in the working and ornamenting of these metals. Homer’s description of the shield of Achilles, made of bronze, enriched with bands of figure reliefs in gold, silver and tin, could hardly have been written by a man who had not some personal acquaintance with works in metal of a very elaborate kind. Again, the accuracy of his descriptions of brazen houses—such as that of Alcinoüs, Od. vii. 81—is borne witness to by Pausanias’s mention of the bronze temple of Athena Akropolis in Sparta, and the bronze chamber dedicated to Myron in 648 B.C., as well as by the discovery of the stags and bronze nails, which show that the whole interior of the so-called treasury of Atreus at Mycenae was once covered with a lining of bronze plates. Of the two chief methods of working bronze, gold and silver, it is probable that the hammer process was first practised, at least for statues, among the Greeks, who themselves attributed the invention of the art of hollow casting to Theodorus and Rhescus, both Samian sculptors, about the middle of the 6th century B.C. Pausanias specially mentions that one of the oldest statues he had ever seen was a large figure of Zeus in Sparta, made of hammered bronze plates riveted together. With increased skill in large castings, and the discovery of the use of cores, by which the fluid bronze was poured into a mere skin-like cavity, hammered or repoussé work was only used in the case of small objects in which lightness was

FIG. 2.—One of the Siris Bronzes.

the treatment of the reliefs is minute and delicate. The “Siris bronzes,” in the same museum, are a most astonishing example of the skill attained by Greek artists in this repoussé work (see Brûnsted’s Bronzes of Siris, 1836). They are a pair of shoulder-pieces from a suit of bronze armour, and each has in very high relief a combat between a Greek warrior and an Amazon. No work of art in metal has probably ever surpassed these little figures for beauty, vigour and expression, while the skill with which the artist has beaten these high reliefs out of a flat plate of metal appears almost miraculous. The heads of the figures are nearly detached from the ground, their substance is little thicker than paper, and yet in no place has the metal been broken through by the punch. They are probably of the school of Praxiteles, and date from the 4th century B.C. (see fig. 2).

Copper and tin have been but little used separately. Copper in its pure state may be worked by the same methods as bronze, but it is inferior to it in hardness, strength and beauty of surface. Tin is too weak and brittle a metal to be employed alone for any but small objects. Some considerable number of tin drinking-cups and bowls of the Celtic period have been found in Cornwall.
METAL-WORK

desirable, or for the precious metals in order to avoid large expenditure of metal. The colossal statues of ivory and gold by Phidias were the most notable examples of this use of gold, especially his statue of Athena in the Parthenon, and the one of Zeus at Olympia. The nude parts, such as face and hands, were of ivory, while the armour and drapery were of beaten gold. The comparatively small weight of gold used by Phidias is very remarkable when the great size of the statues is considered.

A graphic representation of the workshop of a Greek sculptor in bronze is given on a fictile vase in the Berlin Museum (see Gerhard's *Trinkschalen*, plates xii., xiii.). One man is raking out the fire in a high furnace, while another behind is blowing the bellows. Two others are smoothing the surface of a statue with scraping tools, formed like a strigil. A fourth is beating the arm of an unfinished figure, the head of which lies at the workman's feet. Perhaps the most important of early Greek works in cast bronze, both from its size and great historical interest, is the bronze pillar (now in the Hippodrome at Constantinople) which was erected to commemorate the victory of the allied Greek states over the Persians at Plataea in 479 B.C. (see Newton's *Travels in the Levant*). It is in the form of three serpents twisted together, and before the heads were broken off was at least 20 ft. high. It is cast hollow, all in one piece, and has the names of the allied states engraved on the lower part of the coils.

Its size and the beauty of its surface show great technical skill in the founder's art. On it once stood the gold tripod dedicated to Apollo as a tenth of the spoils. It is described by both Herodotus and Pausanias. Marble was comparatively little used by the earlier Greek sculptors, and even Myron, a rather older man than Phidias, seems to have executed nearly all his most important statues in metal. Additional richness was given to Greek bronze-work by gold or silver inlay on lips, eyes and borders of the dress; one remarkable statuette in the British Museum has eyes inlaid with diamonds and fret-work inlay in silver on the border of the chiton. The mirrors of the Greeks are among the most important specimens of their artistic metal-work. These are bronze disks, one side polished to serve as a reflector, and the back ornamented with engraved outline drawings, often of great beauty (see Gerhard, *Eiruskische Spiegel*, 1843-1867). In metal-work, as in other arts, the Romans were pupils and imitators of the Greeks. Owing to the growth of the spirit of luxury, a considerable demand arose for magnificent articles of gold and silver plate. The finest specimens of these that still exist are the very beautiful set of silver plate found buried near Hildesheim in 1869, now in the Berlin Museum. They consist of drinking vessels, bowls, vases, ladies and other objects of silver, parcel gilt, and exquisitely decorated with figures in relief, both cast and repoussé. There are electrotypes of these in the Victoria and Albert Museum. When the seat of the empire was changed, Byzantium became the chief centre for the production of artistic metal-work. From Byzantium the special skill in this art was transmitted in the 9th and 10th centuries to the Rhenish provinces of Germany and to Italy, and thence to the whole of western Europe; in this way the 12th century smith who wrought the Hampton Court iron gates was the heir to the mechanical skill of the ancient metal-workers of Phoenicia and Greece. In that period of extreme degradation into which all the higher arts fell after the destruction of the Roman Empire, though true feeling for beauty and knowledge of the subtleties of the human form remained for centuries almost dormant, yet at Byzantium at least there still survived great technical skill and power in the production of all sorts of metal-work. In the age of Justinian (first half of the 6th century) the great church of St Sophia at Constantinople was adorned with an almost incredible amount of wealth and splendour in the form of screens, altars, candlesticks and other ecclesiastical furniture made of massive gold and silver.

Metall-Work in Italy.—It was therefore to Byzantium that Italy turned for metal-workers, and especially for goldsmiths, when, in the 5th to the 7th centuries, the basilica of St Peter's in Rome was enriched with masses of gold and silver for decorations and fittings, the gifts of many donors from Belisarius to Leo III., the mere catalogue of which reads like a tale from the *Arabian Nights*. The gorgeous Pala d'oro, still in St Mark's at Venice, a gold retable covered with delicate reliefs and enriched with enamels and jewels, was the work of Byzantine artists during the 11th century. This work was in progress for more than a hundred years, and was set in its place in 1106 A.D., though still unfinished (see Bellomo, *Pala d'oro di S. Marco*, 1847). It was, however, especially for the production of bronze doors for churches, ornamented with panels of cast work in high relief, that Italy obtained the services of Byzantine workmen (see Garrucci, *Arte cristiana*, 1872-1882). One artist, named Staurachios, produced many works of this class, some of which still exist, such as the bronze doors of the cathedral of Amalfi, dated 1066 A.D. Probably by the same artist, though his name was written differently, were the bronze doors of San Paolo fuori le Mura, Rome, careful drawings of which exist, though the originals were destroyed in the fire of 1824. Other important examples exist at Ravello (1197), Salerno (1099), Amalfi (1062), Atrani (1087); and doors at Monreale in Sicily and at Trani, signed by an artist named Barisano (end of the 12th century); the reliefs on these last are remarkable for expression and dignity, in spite of their early rudeness of modelling and ignorance of the human figure. Most of these works in bronze were enriched with fine lines inlaid in silver, and in some cases with a kind of niello or enamel. The technical skill of these Byzantine metal-workers was soon acquired by native Italian artists, who produced many important works in bronze similar in style and execution to those of the Byzantine Greeks. Such, for example, are the bronze doors of San Zenone at Verona (unlike the others, of repoussé, not cast work); those of the Duomo of Pisa, cast in 1160 by Bonannus, and of the Duomo of Trani, the last made in the beginning of the 12th century by Oderisius of Benevento. Another artist, named Roger of Amalfi, worked in the same way; and in the year 1210 the brothers Hubertus and Petrus de Piacenza cast the bronze door for one of the side chapels in San Giovanni in Laterano. One of the most important early specimens of metal-work is the gold and silver altar of Sant' Ambrogio in Milan. In character of work and design it resembles the Venice Pala d'Oro, but is still earlier in date, being a gift to the church from Archbishop Angilbert II. in 835 A.D. (see Du Sommerard, and D'Agincourt, *Hymen Age*). It is signed *Wolvinvis Magister Phareb*: nothing is known of the artist, but he probably belonged to the semi-Byzantine school of the Rhine provinces; according to Dr Rock he was an Anglo-Saxon goldsmith. It is a very sumptuous work, the front of the altar being entirely of gold, with repoussé reliefs and cloisonné enamels; the back and ends are of silver, with gold ornaments. On the front are figures of Christ and the twelve apostles; the ends and back have reliefs illustrating the life of St Ambrose.

The most important existing work of art in metal of the 13th century is the great candelabrum now in Milan Cathedral. It is of gilt bronze, more than 14 ft. high; it has seven branches for
candles, and its upright stem is supported on four winged dragons. For delicate and spirited execution, together with refined gracefulness of design, it is unsurpassed by any similar work of art. Every one of the numerous little figures with which it is adorned is worthy of study for the beauty and expression of the face, and the dignified arrangement of the drapery (see fig. 3). The conventional open scroll-work of branches and fruit which wind around and frame each figure or group is devised with the most perfect taste and richness of fancy, while each minute part of this great piece of metal-work is finished with all the care that could have been bestowed on the smallest article of gold jewellery. Though something in the grotesque dragons of the base recalls the Byzantine school, yet the beauty of the figures and the keen feeling for graceful curves and folds in the drapery point to a native Italian as being the artist who produced this wonderful work of art. There is a cast in the Victoria and Albert Museum.

![Fig. 4.—Silver Repoussé Reliefs from the Pistoia Retable.](image)

During the 13th and 14th centuries in Italy the widespread influence of Nicola Pisano and his school encouraged the sculptor to use marble rather than bronze for his work. At this period wrought iron came into general use in the form of screens for chapels and tombs, and grills for windows. These are mostly of great beauty, and show remarkable skill in the use of the hammer, as well as power in adapting the design to the requirements of the material. Among the finest examples of this sort of work are the screens round the tombs of the Scala family at Verona, 1350–1375—a sort of network of light cupped quatrefoils, each filled up with a small ladder (scala) in allusion to the name of the family. The most elaborate specimen of this wrought work is the screen to the Rinuccini chapel in Santa Croce, Florence, of 1371, in which moulded pillars and window-like tracery have been wrought and modelled by the hammer with extraordinary skill (see Wyatt, Metal-Work of Middle Ages). Of about the same date are the almost equally magnificent screens in Sta Trinita, Florence, and at Siena across the chapel in the Palazzo Pubblico. The main part of most of these screens is filled in with quatrefoils, and at the top is an open frieze formed of plate iron pierced, repoussé, and enriched with engraving. In the 14th century great quantities of objects for ecclesiastical use were produced in Italy. The silver altar of the Florence baptistery was begun in the first half of the 14th century, and not completed till after 1477 (see Cas. des beaux-arts, Jan. 1883). The greatest artists in metal laboured on it in succession, among them Orcagna, Ghiberti, Verrocchio, Ant. Pollaiuolo and many others. It has elaborate reliefs in repoussé work, cast canopies and minute statuettes, with the further enrichment of translucent coloured enamels. The silver altar and relatable of Pistoia Cathedral (see fig. 4), and the great shrine at Orvieto, are works of the same class, and of equal importance.

Whole volumes might be devoted to the magnificent works in bronze produced by the Florentine artists of this century, works such as the baptistery gates by Ghiberti, the statues of Verrocchio, Donatello and many others, the bronze screen in Prato cathedral by Simon de Pollaiuolo, brother of Donatello, in 1444–1451, and the screen and bronze ornaments of the tomb of Piero and Giovanni dei Medici in San Lorenzo, Florence, by Verrocchio, in 1472. At the latter part of the 15th century and the beginning of the 16th the Pollaiuoli, Ricci and other artists devoted much labour and artistic skill to the production of candlesticks and smaller objects of bronze, such as door-knockers, many of which are works of the greatest beauty. The candlesticks in the Certosa near Pavia, and in the cathedrals of Venice and Padua, are the finest examples of these. Nicolò Grossi, who worked in wrought iron under the patronage of Lorenzo dei Medici, produced some wonderful specimens of metal-work, such as the candlesticks, lanterns, and rings fixed at intervals round the outside of the great palaces (see fig. 5). The Strozzi palace in Florence and the Palazzo del Magnifico at Siena have fine specimens of these—the former of wrought iron, the latter in cast bronze. At Venice fine work in metal, such as salvers and vases, was being produced, of almost Oriental design, and in some cases the work of resident Arab artisans. In the 16th century Benvenuto Cellini was supreme for skill in the production of enamelled jewellery, plate and even larger works of sculpture (see Plon's Ben. Cellini, 1882), and Giovanni de Bologna in the latter part of the same century inherited to some extent the skill and artistic power of the great 15th-century artists.

**Spain.**—From a very early period the metal-workers of Spain have been distinguished for their skill, especially in the art of repoussé work. A very remarkable set of specimens of goldsmith’s work of the 7th century are the eleven votive crowns, two crosses and other objects found in 1858 at Guarrazar, and now preserved at Madrid and in Paris in the Cluny Museum (see Du Sommerard, Musée de Cluny, 1852). Magnificent works in silver, such as shrines, altar crosses and chalice vessels of all kinds, were produced in Spain from the 14th to the 16th century—especially a number of sumptuous tabernacles (custodia) for the host, magnificent examples of which still exist in the cathedrals of Toledo and Seville. The bronze and wrought-iron screens—rejas, mostly of the 15th and 16th centuries—to be found in almost every important church in Spain are very fine examples of metal-work. They generally have moulded rails or balusters, and rich friezes of pierced and repoussé work, the whole being often thickly plated with silver. The common use of metal for pulpits is a peculiarity.
of Spain; they are sometimes of bronze, as the pairs in Burgos and Toledo cathedrals, or in wrought iron, like those at Zamora and in the church of San Gil, Burgos. The great candelabrum or *tenebrarium* in Seville Cathedral is the finest specimen of 16th-century metal-work in Spain; it was mainly the work of Bart. Morel in 1562. It is of cast bronze enriched with delicate scroll-work foliage, and with numbers of well-modelled statuettes. Especially in the art of metal-work Spain was much influenced in the 15th and 16th centuries by both Italy and Germany, so that numberless Spanish objects produced at that time owe little or nothing to native designers. At an earlier period Arab and Moorish influence is no less apparent.

*Fig. 6.—Part of the "Eleanor Grill."*

**England.**—In Saxon times the English metal-workers, especially of the precious metals, possessed great skill, and appear to have produced shrines, altar-frontals, retables and other ecclesiastical furniture of considerable size and magnificence. Dunstan, archbishop of Canterbury (925-988), like Bernward, bishop of Hildesheim a few years later, and St Eloi of France three centuries earlier, was himself a skilful worker in all kinds of metal. The description of the gold and silver retable given to the high altar of Ely by Abbot Theodwin in the 11th century, shows it to have been a large and elaborate piece of work decorated with many reliefs and figures in the round. In 1241 Henry III. gave the order for the great gold shrine to contain the bones of Edward the Confessor. It was the work of members of the Otro family, among whom the goldsmith's and coiner's crafts appear to have been long hereditary. Countless other important works in the precious metals adorned every abbey and cathedral church in the kingdom. In the 13th century the English workers in wrought iron were especially skilful. The grill over the tomb of Queen Eleanor at Westminster, by Thomas de Leghton, made about 1294, is a remarkable example of skill in welding and modelling with the hammer (see fig. 6). The rich and graceful iron hinges, made often for small and out-of-the-way country churches, are a large and important class in the list of English wrought-iron work. Those on the refectory door of Merton College, Oxford, are a beautiful and well-preserved example dating from the 14th century. More mechanical in execution, though still very rich in effect, is that sort of iron tracery work produced by cutting out patterns in plate, and superimposing one plate over the other, so as to give richness of effect by the shadows produced by these varying planes. The screen by Henry V.'s tomb at Westminster is a good early specimen of this kind of work. The screen to Bishop West's chapel at Ely, and that round Edward VI.'s tomb at Windsor, both made towards the end of the 15th century, are the most magnificent English examples of wrought iron; and much wrought-iron work of great beauty was produced at the beginning of the 18th century, especially under the superintendence of Sir Christopher Wren (see Ebbets, *Iron Work of 17th and 18th Centuries*, 1886). Large flowing leaves of acanthus and other plants were beaten out with wonderful spirit and beauty of curve. The gates from Hampton Court are the finest examples of this class of work (see fig. 7).

From an early period bronze and latten (a variety of brass) were much used in England for the smaller objects both of ecclesiastical and domestic use, but except for tombs and lecterns were but little used on a large scale till the 16th century. The full-length recumbent effigies of Henry III. and Queen Eleanor at Westminster, cast in bronze by the "cire perdue" process, and thickly gilt, are equal, if not superior, in artistic beauty to any sculptor's work of the same period (end of the 13th century) that was produced in Italy or elsewhere. These effigies are the work of an Englishman named William Torek. The gates to Henry VII.'s chapel, and the screen round his tomb at Westminster (see fig. 8), are very elaborate and beautiful examples of "latten" work, showing the greatest technical skill in the founder's art. In latten also were produced the numerous monumental brasses of which a large number still exist in England (see *Brasses, Monumental*).

In addition to its chief use as a roof covering, lead was sometimes used in England for making fonts, generally tub-shaped, with figures cast in relief. Many examples exist: e.g. at Tidenham, Gloucestershire; Warbord and Dorchester Oxon; Chirton, Wilts; and other places.

METAL-WORK

GEOMANY.—Unlike England, Germany in the 10th and 11th centuries produced large and elaborate works in cast bronze, especially doors for churches, much resembling the contemporaneous doors made in Italy under Byzantine influence. Bernward, bishop of Hildesheim, 992-1022, was especially skilled in this work, and was much influenced in design by a visit to Rome in the suite of Otto III. The bronze column with winding reliefs now at Hildesheim was the result of his study of Trajan’s column, and the bronze door which he made for his own cathedral shows classical influence, especially in the composition of the drapery of the figures in the panels. The bronze doors of Augsburg (1047-1072) are similar in style. The bronze tomb of Rudolph of Swabia in Merseburg Cathedral (1080) is another fine work of the same school. The production of works in gold and silver was also carried on vigorously in Germany. The shrine of the three kings at Cologne is the finest surviving example. At a later time Augsburg and Nuremberg were the chief centres for the production of artistic works in the various metals. Hermann Vischer, in the 15th century, and his son and grandsons were very remarkable as bronze founders. The font at Wittenberg, decorated with reliefs of the apostles, was the work of the elder Vischer, while Peter and his son produced, among other important works, the shrine of St Sebald at Nuremberg, a work of great finish and of astonishing richness of fancy in its design. The tomb of Maximilian I., and the statues round it, at Innsbruck, begun in 1521, are perhaps the most meritorious German work of this class in the 16th century, and show considerable Italian influence. In wrought iron the German smiths, especially during the 15th century, greatly excelled. Almost peculiar to Germany is the use of wrought iron for grave-crossees and sepulchral monuments, of which the Nuremberg and other cemeteries contain fine examples. Many elaborate well-canopies were made in wrought iron, and gave full play to the fancy and invention of the smith. The celebrated 15th-century example over the well at Antwerp, attributed to Quintin Matsys, is the finest of these.

FRANCE.—From the time of the Romans the city of Limoges has been celebrated for all sorts of metal-work, and especially for brass enriched with enamel. In the 13th and 14th centuries many life-size sepulchral effigies were made of beaten copper or bronze, and ornamented by various-coloured “champlevé” enamels. The beauty of these effigies led to their being imported into England; most are now destroyed, but a fine specimen still exists at Westminster on the tomb of William de Valence (1256). In the ornamental iron-work for doors the French smiths were pre-eminent for the richness of design and skilful treatment of their metal. Probably no examples surpass those on the west doors of Notre Dame in Paris—unhappily much falsified by restoration. The crockets and finials on the fleches of Amiens and Rheims are beautiful specimens of a highly ornamental treatment of cast lead, for which France was especially celebrated. In most respects, however, the development of

Fig. 9.—Brass Vase, pierced and gilt; 17th century Persian work.
the various kinds of metal-working went through much the same stages as in England.

_Persia and Damascus._—The metal-workers of the East, especially in brass and steel, were renowned for their skill even in the time of Theophilus, the monkish writer on the subject in the 13th century. But it was during the reign of Shah Abbas I. (d. 1628) that the greatest amount of skill both in design and execution was reached by the Persian workmen. Delicate pierced vessels of gilt brass, enriched by tooling and inlay of gold and silver, were among the chief specialties of the Persians (see fig. 6). A process called by Europeans “damascening” (from Damascus, the chief seat of the export) was used to produce very delicate and rich surface ornament. A pattern was incised with a graver in iron or steel, and then gold wire was beaten into the sunk lines, the whole surface being then smoothed and polished. In the time of Cellini this process was copied in Italy, usually the tiny figures and inscriptions of weapons and armour. The repoussé process both for brass and silver was much used by Oriental workers, and even now fine works of this class are produced in the East, old designs still being adhered to.

(J. H. M.)

_Modern Art Metal-Work._—The term “art metal-work” is applied to those works in metal in which beauty of form or decorative effect is the first consideration, irrespective of whether the object is intended for use or is merely ornamental; and it embraces any article from a Birmingham brass bedstead to works of the highest artistic merit. The term, as definitely distinguishing one branch of metal-working from another, is objected to by many on the ground that no such prefix was required in the best periods of art, and that allied crafts continue to do without it to the present day. Indeed, as long as metal-working remained a handicraft—in other words, until the introduction of steam machinery—every article, however humble its purpose, seems to have been endowed with some traditional beauty of form. The robust, florid and distinctly Roman rendering of the classic, which followed the refined and attenuated treatment associated with the architecture of the brothers Adam, who died in 1792 and 1794, is the last development in England which can be regarded as a national style. The massively moulded ormulu stair balustrade of Northumberland House, now at 40 Prince’s Gate; the candelabra at Windsor and Buckingham Palace, produced in Birmingham by the firm of Messenger; the cast-iron railings with jaspe heads and licent’s faces, the tripods, Corinthian column standard lamps and candelabra, boat-shaped oil lamps and tent-shaped lustres with classic mountings, are examples of the metal-work of a style which, outside the eccentric Brighton Pavilion and excursions into “Gothic” and Elizabethan, was under threat rejected in the United Kingdom from the beginning of the Regency until after the accession of Victoria. Except perhaps the silversmiths, no one was conscious of being engaged in “art metal-working,” yet the average is neither vulgar nor in bad taste, and the larger works are both dignified and suited to their architectural surroundings.

The introduction of gas as an illuminant, about 1816, at once induced a large demand and a novel description of metal fitting; and the craft fell under the control of a new commercial class, intent on breaking with past traditions, and utilizing steam power, electricity, and every mechanical and scientific invention tending to economize metal or labour. But when all artistic perception in Great Britain appeared lost in admiration of the triumphs of machinery and the expansion of trade, a new influence in art matters, that of the Prince consort, began to make itself felt. The Great Exhibition, state-aided schools of design, the South Kensington Museum, and the establishment of a Science and Art Department under Government, were among the results of the important art revival which he inaugurated. He is credited with having himself designed candelabra and other objects in metal, and he directly encouraged the production of the sumptuous treatise on metal-work by Digby Wyatt, which laid the foundations of the revival. To this work, and that of Owen Jones, can be traced the origin of the eclecticism which has laid all past styles of art under contribution. The Gothic revival also helped the recognition of art, without very directly affecting the movement. It was valuable in teaching how to work within definite limitations, but without slavish copying; it also emancipated a considerable body of craftsmen from the tyranny of manufacturers whose sole idea was that machine-work should supersede handicraft. Its greatest efforts were the metal chancel-screen designed by Sir G. G. Scott, that for Hereford Cathedral having been exhibited in 1862. It does not appear that the influence either of Owen Jones or Digby Wyatt on metal-working extended beyond bringing the variety and beauty of past styles to the direct notice of designers. Neither can the London silversmiths, though they employed the best talent available, particularly in the decade following the Great Exhibition of 1851, be credited with much influencing the art metal revival. They were rivalled by Edward Lader of Birmingham, who secured the permanent assistance of at least one fine artist, Mr. Ladeuil, the producer of the Echo Challenge Shield. Perhaps the first actual designer to make a lasting impression on the crafts was Thomas Jeckyll, some of whose work, including gates for Sandringham, was exhibited in 1862. Infinitely greater as a designer was Alfred Stevens, whose influence on English craftsmen might be regarded as almost comparable to that of Michelangelo on that of his Italian contemporaries. Stevens’s designs certainly directly raised the standard of production in several metal-working firms by whom he was employed; whilst in the Wellington Memorial in St Paul’s Cathedral, and in Dorchester House, his work is seen unfettered by commercial considerations. Omitting many whose occasional designs have had little influence on the development of the metal crafts, we come to Alfred Gilbert, whose influence for a time was scarcely less than that of Stevens himself. Monumental works, such as his statue of Queen Victoria at Winchester and his work at Windsor, may be handed down as his greatest achievements, but judged as art metal-work, his smaller productions, such as the centrepiece presented by the army and navy to Queen Victoria on her Jubilee, have been more important.

The charming bronze statuettes of Onslow Ford, the most representative of which are in the Tate Gallery; the work of George Frampton, as seen in the Mitchell Memorial; and the beautiful bas-reliefs of W. Stirling Lee, examples of which are the bronze gates of the Adelphi Bank at Liverpool, have all contributed, especially when applied to architectural decoration, to a high standard of excellence. Painters also have frequently designed and modelled for metal-work, for example, Lord Leighton, who produced bronze statuettes of most refined character; and Sir L. Alma-Tadema, who designed the grilles for his studio and entrance hall; but none so conspicuously as Professor H. von Herkomer, who, whether working in gold and enamel, iron, or his favourite alloy, pewter, infuses a freshness into his designs and methods which displays an unusual mastery over materials.

The gift of reproducing effects of nature or art by brush or chisel is not necessarily accompanied by power to design; but a noteworthy exponent of the dual faculty is G. C. Haïtè, whose designs are widely applied.

It is chiefly to architecture that metal-work owes its permanent artistic improvement. In England buildings of Norman Shaw and Ernest George demanded quiet and harmonious metal-work; and the custom of these architects of superintending and designing every detail, even for interiors, created the supply. The work of every worthy architect raises the standard of the crafts; but beyond others Messrs Asbee, Lethaby and Wilson have taken an active personal interest in schools of metal-work. The technical schools have also been of immense service in creating a class of self-respecting craftsmen, whose wages enable them to regard their work as worthy occupation abounding in interest. Home industries such as the metal-working round Keswick (founded in 1884 by Canon and Mrs Ransney), executed during hours of idleness by field labourers and railway porters, educate the passer-by as well as the worker.
CAST BRONZE GATES, ADELPHI BANK, LIVERPOOL.
Designed by W. D. Caroe, the figures by Stirling Lee, executed by Starkie Gardner and Co.
PLATE II.

METAL-WORK

RAIN-WATER HEAD, IN LEAD, FOR THE VICTORIA LAW COURTS, BIRMINGHAM.
Designed by Aston Webb and Ingres Bell, and executed by Dent and Hellier.

COVERED BRIDGE OF IRON, SHEATHED IN CAST LEAD, GRAND HOTEL, LONDON.
Designed by William Woodward, and executed by Starkie Gardner and Co.
British architects and artists who design for the principal decorating firms are to-day as conversant with the Renaissance and succeeding styles of France and Italy as medieval revivalists were familiar with the Gothic styles with which they made us so well acquainted. Metal-work more or less based upon every kind of past style is produced in vast quantities, and in some cases so skilful are the workers that modern forgeries and reproductions are almost beyond the power of experts to detect. This large class of designers and craftsmen, to whom a thorough knowledge of the history of design is a necessity, follows and develops traditional lines. The new art school, on the contrary, breaks wholly with tradition, unless unconsciously influenced by the Japanese, and awards the highest place to originality in design. It is not to be expected that an art-revival following on, and in possession of, all the results of a period of unprecedented activity in scientific research should proceed with the same restraint as heretofore; but the unfettered activity, and the general encouragement to abandon the traditions of art, have no exact parallel in the past, and may yet prove a danger. It is perhaps the very rapidity of the movement that is likely to retard its progress, and to fortify carries with it the wealth of expertise and the decadent art they employ, or perhaps even to increase the disposition to cling to the reproductions of the styles of the 17th and 18th centuries. The multiplication of art periodicals, lectures, books, photographs, meetings of societies and gilds, museums, schools of arts and crafts, polytechnics, scholarships, facilities for travel, exhibitions, even those of the Royal Academy, to which objects of applied art are now admitted, not only encourages many persons to become workers and designers in the applied arts, but exposes everything to the plagiarist, who travesties the freshest idea before it has well left the hands of its originator. Thus the inspirations of genius, appropriated by those who imperfectly appreciate their subtle beauty and quality, become hackneyed and lose their charm and interest. The keen desire to be unconventional in applied art has spread from Great Britain and the United States to Germany, Austria and other countries, but without well-defined first principles, or limitations. It seems agreed in a general way that the completed work in metal is to be wholly the conception and, as far as possible, the actual handwork of the designer: casting by the cire-perdue process, left practically untouched from the mould, and embossing, being the two most favoured processes. The female figure is largely made use of, and rich and harmonious colours are sought, the glitter of metal being invariably subdued by deadening its lustre, or by patinas and oxides. Gilding, stains and lacquers, electro-plating, chasing, "matting," frosting, burnishing, mechanically produced mouldings and enrichments, and the other processes esteemed in the 19th century, are disused and avoided. New contrasts are formed by the juxtaposition of differently toned metals; or these with an inlay of halliotis shell, introduced by Alfred Gilbert; or of coloured wax, favoured by Onslow Ford; or enamelling, perfected by Professor von Herkomer; or stained ivory, pearls, or semi-precious stones. The quality of the surface left by the enamelled artist or artisan is much neglected, renewed by symmetry of design, the perfecting of the requisite metal. Frenchmen, the important parts in a design are carefully finished and the rest merely sketched: the mode of working, whether by modelling-tools or hammer, being always left apparent.

The newer kinds of art metal-work have, until recently, reached the purchaser direct from the producer's workshop; but they may now also be seen in the shops of silversmiths, jewellers, and general dealers, who are thus helping to transfer production from large commercial manufactories to smaller ateliers under artistic control. The production of the larger household accessories, such as bedsteads, fenders, gas and electric fittings, clocks, &c., has hardly as yet come under the influence of the art movement. The services rendered by Mr. W. A. S. Benson of Chiswick, who commenced about 1886 to revolutionize the production of sheet-brass and copper utensils, cannot be passed over. The average ecclesiastical metal-work has rather receded than progressed in merit, except when designed by architects and executed under their supervision. Though the demand for good domestic wrought-iron work has enormously increased, adaptations from the beautiful work of the 17th and 18th centuries have been found so suited to their architectural surroundings, that new departures have been relatively uncommon. Of such the gates for Sandringham, by Jeckyll; for Crewe Hall, by Charles Barry; and for the Victoria and Albert Museum, by Gamble, are the earliest and best known. Of the vast number designed upon traditional lines may be cited those for Lambton Castle, Welbeck, Eaton Hall, Twickenham, Cliveden, and the Astor Estate Office on the Victoria Embankment. Cast iron, brought to perfection by the Coalbrookdale Company about 1860, but now little esteemed, owing to the poverty of design which so often counterfeits smiths' work, presents great opportunities to founders possessing taste or willing to submit to artistic control. A very large field is also opening for cast-lead work, whether associated with architecture, as in the leaden covered-way over Northumberland Street, in London (see Plate), and the fine rain-water heads of the Birmingham Law Courts (see the same), or with the revival of the use of metal statuary and vases in gardens. The subdue colour and soft contours of pewter render it once more a favoured material, peculiarly adapted to the methods of the art revival, and perhaps destined to supersede electro-plate for household purposes. In silver-work the proportion of new art designs exhibited by dealers and others is still relatively small; but jewellers, except when setting pure brilliants and pearls, are becoming more inclined to make their jewels of finely modelled gold and enamel enriched with precious and semi-precious stones, than of gems merely held together by wholly subordinate settings.

On the continent of Europe, France was the first to recognize the merits of its bygone designers and craftsmen, and even antecedent to the Exhibition of 1851, when art in Great Britain was dormant, it was possible to obtain in Paris faithful reproductions of the finest ormulu work of the 18th century. At the same time a most active production of modern designs was proceeding, stimulated by rewards, with the result that the supply of clocks, lamps, candelabrum, statuettes, and other ornaments in bronze and zinc to the rest of Europe became a monopoly of Paris for nearly half a century. In all connected with their own homes the French adhere to their traditions far more than other nations, and the attempt at originality in the introduction of metal-work into the scheme of decoration of a room is almost unknown. In the domain of bronze and imitation bronze statuary the originality of the French is absolutely unrivalled. And not only in bronze, but in Paris jewellery, enamels, silver, pewter and iron work a cultured refinement is apparent, beside which other productions, even the most finished, appear crude. The French artist attains his ideal, and it is difficult to imagine, from his standpoint, that the metal-work of the present can be surpassed. The best English metal-worker, on the contrary, is probably not often quite satisfied with the results he attains, perhaps because in Great Britain the pursuit of art has for centuries been a fitful individual, while in France art traditions are hereditary. The metal-work of Belgium is based at present entirely on that of France, without attaining the same standard, unless designed for ecclesiastical uses. In Holland these crafts have not progressed. Italian metal-workers are mainly employed in reproduction; but traditions linger in some remote parts, while the sporadic appearance of craftsmen of a high order is evidence that the ancient artistic spirit is not wholly extinct. Similarly, the surprising damascening by Messrs Zuluaga of Madrid in the monument to General Prim, and that of Alvarez of Toledo, give hope that the Spanish craftsman only needs to be properly directed. German and Austrian workers had for years shown more energy than originality; but they have recently embraced the newest English developments and carried them to extremes of exaggeration. For really fresh and progressive indigenous art we may perhaps have, in the near future, to turn to America.
METAL-WORK

and to Russia, where, having little artistic past to refer to, designers and craftsmen display unequalled individuality and force. It is from the Far East, however, that the most serious rivalry may be anticipated. The metal-work of China and Japan, so pleasantly naïve and inexpensive, though becoming undesirably modified as to design through contact with European buyers, is losing none of its matchless technique, which indeed in Japan is still being developed. In any history of the art revival the influence of such firms as Barbedienne and Christofle in Paris and Tiffany in New York cannot be ignored.

Industrial Metal-Work.

The malleability and ductility of metals lie at the basis of the work of the gold- and silver-smith, and of the jeweller and of the boiler-maker at the other. Sheet metals can be made to assume almost any shape under the hammer, or by pressure, provided they are subjected to annealing to restore the property of malleability. The most awkward shapes, involving excessive extensions of metal, are produced by drawing processes between dies of iron and steel in power presses. All the common domestic utensils in tinned and enamelled ware, and all the ordinary patterns of the silversmiths, are similarly done. Frequent annealings are necessary to prevent fracture of the metal; but with these and the observance of certain other precautions of a practical character the degree of extension possible is enormous. Another illustration of the malleability of metal is shown by the mechanical properties of a strip of copper. If drawn out uniformly until it is very thin, then rolled into a sheet, this sheet, if bent high in the lathe is bent over into cup-shaped forms with numerous mouldings, by a blunted hardened tool. A great deal of work is done in this way, though this sphere has also been invaded by sheet metal manufacture. Of the metals, of the thin sheets, those thicknesses they are used chiefly for the largest marine boilers. Armour plates which are several inches in thickness do not come in this group, being a special article of manufacture. Sheets are wrought of thicknesses of less than ¼ in. This distinction of thickness is of importance in its bearing on workshop practice. A thin sheet requires a very different kind of treatment from a thick plate. Not only is more powerful machinery required for the latter, but, in bending, the former can only be bent against the outside of the outer and inner layers, which increases with increase of thickness. Short, sharp bends which are readily made in thin sheets cannot be done in thick plates, as the metal would be stressed too much in the middle. The method most generally adopted for thick plates, and soldering or brazing generally for thin, is known as the plate process of being allowed to cool from the fire, and are then cut and mitered out, and the dimensions are taken as in the middle of the plate, but they may be on the inside or outside according to circumstances. But in any case the thickness must enter into the calculations, whereas in thin sheets no account is taken of thickness. 

Cast Work.—The sheets of metal that are bent in one plane only are easily made. The shapes of all polygonal and all cylindrical and conical forms are obtained by simple development—that is, the envelopments of these bodies are marked out on a flat surface and then cut out, and the sheet so developed. Only common geometrical problems are involved in the case of sheets of sensible thickness, and allowances are made for thickness. But in those forms where curving must take place in different directions in the layers, and in the two directions, and for part one and part another, extension taking place in some layers but not in others, and this goes on without producing much reduction in the thickness, this is only possible with malleable and ductile metals and alloys. In the case of those metals, in which, however, even with some slight exceptions, it is impossible to produce relative movements of the layers in cast iron, steel or cast brass, but most rolled metals and alloys can be so treated, copper being the best for the purpose. The methods employed are "raveling" by the hammer, and pressing in dies. But the severity of the treatment would tear the material asunder if rearrangement of the particles was not obtained by frequent annealing (g.e.).

If an object has to be beaten into concave form from a flat thin sheet, the outer portions must be hammered until they occupy smaller dimensions than on the flat sheet. If a circular disk is wrought into a hemisphere and the attempt is made to hammer the edge up to the surface, it would be broken off by the observation, termed wrinkling, the edge showing a series of flutes. These flutes have to be obliterated by a second series of hammerings termed razing. The result is that the object assumes a smooth concave and convex shape, without the thickness of the metal becoming reduced.

Cast Work.—The metals and alloys which are neither malleable nor ductile can only be worked into required shapes by melting and casting. This is the process of casting on the one hand, and for forgings also die-casting. Neolithic period testifies to the high antiquity of this class of work, and also to the great skill which the ancient founders had acquired. Statue-making is a highly specialized department of metal-work, in which the greatest precision is required. The most valuable results have been employed, the cire-perdue, or wax process (see above), and the present, or all sand method. In the latter the artist provides a model in plaster from which the founder takes a mould within an conceivable space when the molten metal is poured. In the other little separate sections (false cores or drawbacks) to permit of their removal from the mould without causing fracture of the sand. These are subsequently replaced piece by piece in the encircling frame, and a core made within it, leaving a space of ½ in. or thereabouts into which the metal is poured. The advantage of this process is that the artist’s model is not destroyed as in the cire-perdue, and if a “waster” results, a second mould can be taken. A large amount occurs in the production of dies and matrixes.

The extreme tenuity of objects which are hammered, drawn or rolled cannot for obvious reasons be attained by casting. Casting also is complicated by the shrinkage which occurs in cooling down and by the formation of the grain, or, to use a mechanical term, of eutectics, and the liquation of some constituents. The temperature of pouring is known to be of more importance than was formerly suspected. The after-treatment of castings by annealing exercises great influence on results in malleable cast iron and steel.

There are many metals and alloys which are malleable and ductile, and also readily fused and cast. This is the case with gold, silver, copper, tin, lead and others, and especially with low carbon steel, iron, and brass. The latter is cast in its ingot, then annealed and rolled into plates as well as the thinnest sheets. The ancient woof, and the products of the native furnaces of Africa are first cast, then hammered out thin. Many of the patent bronzes are by slight variations in the metals forming the eutectics used for the same purposes, that is, for forging, and for rolling into sheets. But in all the great modern manufacturing processes it is true that metals and alloys, though of the same name, have a different composition according as they are wrought, and their use is so different from the casting method or forging and drawing on the other. Wrought or malleable iron has less of carbon and other elements in its composition than has cast iron. Steel intended for castings has slightly more carbon and other elements than wrought iron, and well suited for wrought iron. So also with the numerous bronzes, the phosphor, the delta, the aluminum and other alloys of copper; each is made in several grades to render it suitable for different kinds of treatment.

The most difficult problem of which the craftsman is to be able to vary the composition and physical qualities so extensively as the metals and their alloys. Much light has been thrown on facts which have long been known in a practical way, by the work of the late Mr. A. W. Francis, of the Centenary Committee of the British Association for the Advancement of Science, and by the late Mr. H. J. Petrie of the Institution of Mechanical Engineers (England). These, together with independent researches into the heat treatment of steel and iron, have opened up many unsolved problems fraught with deepest interest and importance.

One of the most difficult problems with which the metal-worker
who handles constructional forms has to do is the maintenance of a due relation between absolute strength and a useful degree of elasticity. Only after many failures has the fact been grasped that only a very high degree of strength is inconsistent with a trustworthy degree of elasticity. To attain this end diverse researches of Wöhler demonstrated the difference between the effects of merely dead loads and of live loads, and between repetitions of stress of one kind only, and the vastly more destructive effects of both kinds alternating.

The texture of the metals and alloys is related to the character of the operations which can be done upon them. Broadly the malleable and ductile metals and alloys show a fibrous character when ruptured, the fusible ones a crystalline fracture. The difference is seen both in the workshop and in the specimens of testing-machines. A piece of wrought iron, or mild steel or copper, if torn asunder shows long lustrous fibres, resembling a bundle of threads in appearance. A piece of cast iron, or steel or bronze, shows a more or less bright, or dark, the metallic lustre of a fibre. The ductile metals and alloys also extend from 10 to 30% with reduction of area before they fracture, the crystalline ones snap shortly without warning. In some instances, however, the metals and alloys have been found to possess, in varying degrees, both characteristics, and must be carefully not to treatment suitable to one kind to another of a dissimilar character. Tools, appliances and machines have little in common. Between the work of the miner and the work of the ploughman there is a great gulf. An artistic taste will recognize the essential differences, and not endeavour, apart from questions of strength, to graft a design suitable for one on another. It is bad taste to imitate that which is structurally unsuitable. A ductile crack is a less equal state of things. When wrought-iron grilles and screens in heavy cast iron. Severe simplicity is also most in harmony with constructive designs in plated work, where stress occurs in straight lines. In that point of view the lattice-girder bridge is an ideal design in steel.

One of the most valuable characteristics of the iron alloys is their capacity for hardening, which they owe in the main to the presence of carbon. The malleable and ductile metals have also quantities of other elements: as manganese, tungsten, nickel and others of less importance. The capacity for hardening or an invaluable property not only in regard to cutting-tools, but also in prolonging the life of parts subjected to severe friction. Great advances have been made in the utilization of this property as a result of the growth of the precision grinding-machines, which are able to correct the inaccuracies of hardened work as effectually as those of soft materials. It is utilized in the spindles of machine-tools, the rolls and rollers for high-speed bearings, slides, pivots and such like.

Methods of Union.—The methods of union of works in metal are extremely varied. An advantage in casting is that the most complicated parts and models can be made at one time. But in complicated forms have to be united by other means—as welding, soldering, riveting or bolting. The two first-named are trustworthy, but are evidently unsuitable for the greater portion of engineers’ work, for the heat of soldering and welding produces considerable distortion of the simple elements of rivets and bolts have produced immense developments since the days when bolts were made by hand, holes bored or hand-drilled, and rivets formed and closed by hand labour. When bolts are treated with the cold, or by cold and screw cutting, operates automatically, and drilling machinery is highly specialized. Hand-riveting on large contracts has been wholly displaced by power-riveting machines. The methods of union of works in metal are extremely varied. A small amount of work is treated by the Bower-Barff and allied processes, by which a coating of magnetic oxide is left on the metal. Hot tar—Angus Smith’s process—is used for water-pipes. Baked linseed-oil is employed as a coating-preparation, and oil paints are applied to the surface of the metal. In steam boilers artificial galvanic couples are often set up by the suspension of zinc plates in the boiler, so that the corrosion of the zinc may protect the steel boiler plates from rust. Various artificial protective coatings are applied to the surface of the metal. A pound of this protective application may be treated with lacquer or with lacquer. The ornamental bronzes and brasses are generally lacquered, though in engineers’ machinery they are as a rule not protected with any coating. For ornamental work lacquering divides favour with colouring sometimes done with coloured and lacquers, but often with chemical colourings, of which the copper and iron salts are the chief basis.

LITERATURE.—Prehistoric: Worsaae, Nordiske Oldsager i Kjoben- havn (1854); Perrin, Etude préhistorique—Age du bronze (1870). Classical: Layard, Ninive and Babylons (1853); Pliny, Natural History, bk. xxiv.; Bröndsted, Den Finskone Krista (1847); and various monographs (1854-1858), and other works; Ciampi, Dell’ Antica toretica (1851); Von Bibra, Die Bronzen und Kupfer-Feuerungen der alten und älteren Volker (1869); C. Bischoff, Das Kupfer in der vorchristlichen Zeit (1865); and other works; Hefner-Altenburg, Das Metall Material der Mittelalter (1865); and other works; Ornament-Werke (1865); Drury Funttum, S.K.M. Handbook of Bronzes (1877); King, Orférerie et ouvrages en métal du moyen âge (1852-1854); Hefner-Altenburg, Ornament-Werke (1865); Versorger des Metal.—Allt. D. Metall-Werk (1869); and Ornament-Werke (1865), and Britten, Alte und neue Orférerie (1858 & c.); Lacroix, Trésor de S. Denis, L’Art du moyen âge (various dates); Karch, Die Räthselspil von der Bronze- und Silberlegierung zu Augsburg (1863); Krug, Entwürfe für Gold-, Silber- und Bronzelegierungen (1867); and Ornament-Werke (1865), and Ornament-Werke (1865); and Ornament-Werke (1865).

METAMERISM (Gr. μέτα, after, πέσις, a part), a technical term used in natural science: In chemistry it denotes the existence of different substances containing the same elements in the same proportions and having the same molecular weight; it is a form of isomerism.

In zoology, metamterism is the repetition of parts in an organized body, a phenomenon which is, as E. Haenke. W. Bateson and others have repeatedly observed, of the tendency to repetition of structural units or parts which finds one expression in a bilateral symmetry. It occurs in almost every group of the animal kingdom, but is most conspicuous in segmented worms, arthropods and vertebrates. In certain worms (the Cestoidea and some Planarians) metamterism is accompanied by the separation of the completed metameres one by one from the older (anterior) extremity of the chain (strobilation), but by no means follows that metamterism has a necessary origin in such completion and separation of the "meres." On the contrary, metamterism seems to arise from a property of organisms which is sometimes more (eumeregenostasis) and sometimes less (dysermogenostasis) fully exhibited, and in some groups not exhibited at all. The most complete and, at the same time, simplest instances of metamterism are to be seen in the larger Chelopods, where many segments of a Gasteropod succeed the other—the one—after another—e.g. in the higher Crustacean.

We can state as a FIRST LAW of metamterism or somite formation: that the number of segments of the organism is also the precise number found in all the higher Crustacean.
that it is either indefinite in regard to number of metameres or somites produced, or is definite. Animals in the first case we call homomeristic; those in the second case, homonomeristic. The homonomeristic condition is a higher development, a specialization, of the homomeristic condition.

The SECOND LAW, or generalization, as to metamerism which must be noted is that the meres or somites (excepting the first with its prostomium) may be all practically alike or may differ from one another in the least degree, this being the condition of commissure. Thus, in fishes the pelvic fins may travel forwards to a thoracic and even jugal position in front of the pectoral fins; the branchiomeres lose all relation to the position of the merones of muscular, skeletal, coelomic and tegumentary parts; and their vessels may move backwards from their original metameres, in higher vertebrates, carrying nerve-loops with them.

The SEVENTH LAW of metamerism is one which has been pointed out to the writer by E. S. Goodrich. It may be called the law of 'transposition or heterosis': the shifting, by metamere or somite, of the substance of meromes undeniably takes place in such a case as the passage of the pelvic fins of some fishes to the front of the pectorals, and in the case of the backward movement of the opisthomerous crustaceans. In any case, a somite or the whole series, in which an alteration in the position of a specialized organ in the series or scale of metameres takes place is not by migration of the actual material organ from somite to somite, but by translocation of a certain condition or property from somite to somite, accompanied by correlative change in all the somites of the series. The phenomenon may be compared to the transposition of a piece of music to a higher or lower key. It is thus that the lateral fins of fishes move up and down the scale of vertebral somites; and thus that whole regions (tagmata), such as those indicated by the names cervical, thoracic, lumbar and sacral, are translated (accompanied by terminal increase or decrease in the total number of their vertebrae) to occupy differing numerical positions in closely allied forms (cf. the varying number of cervical vertebrae in allied Reptiles and Birds).

What, in this rapid enumeration, we will venture to call the BIAS of metamerism is the inclination to the likeness of one belonging to another metamer, and is the opposite of the process of 'heterosis'—already mentioned. We cite this law as one of the principal causes of the common metameric condition and we call each a tagma (tagyia, a regiment). The word 'tagmosis' is applicable to the formation of such regions. In the Chaetopoda metagomosis always occurs to a small extent so as to form the head.

In some cases, as Chaetopoda, we find a condition which we term metameric and we call each a tagma (tagyia, a regiment). The word 'tagmosis' is applicable to the formation of such regions. In the Chaetopoda metagomosis always occurs to a small extent so as to form the head.

The FOURTH LAW of metamerism (auto-heterosis of the meromes) is that the meromes of a somite or series of somites may be separately and dissimilarly affected by heteromerism. It is common enough for some metameres or somites to have lost or received special characters. The sixth law, if the appendages and terga or sterna are largely changed in form. But of equal importance is the independent 'heterosis' of these visceral meromes without any corresponding heterosis of the body wall. In the case of the coelomic system we find the special localization of renal, genital and gastric meromes, and with obliteration elsewhere, in a few somites in Arthropoda.

The FIFTH LAW, relating also to the independence of the meromes as compared with the somites, is that the appendages, in the same manner, may vary independently of the meromes. Metamerism does not always manifest itself in the formation of complete new segments; but one merome may be repeated so as to suggest several metameres, whilst the remaining metameres of the segment are new. A repetition of this kind is the repetition. Thus in the hind somites of the body of Apsus the crustacean we find a series of segments corresponding apparently each to a complete single somite; but when the appendages are examined it is found they have lost or received their usual character. The other meromes of a somite: we find that the somites carry from two to seven pairs of appendages, increasing in number as we pass backwards from the genital segment. The appendages are autotomous and independent, and in this manner a number of independent metamerism and are produced in numbers which have no relation to the numbers of the body-rings, muscles and meromes. This possibility of the independent metameric multiplication of a single metamer of a somite has great importance in the case of dislocated meromes, and no direct application to some of the metameric phenomena of Vertebrata.

The SIXTH LAW is the law of dislocation of meromes. This is a very important and striking phenomenon. A merome, such as a pair of legs, of appendages (involuntary frequent), may (by either a gradual or sudden process, we cannot always say which) quit the metamer to which it belongs, and in which it originated, and pass by actual physical transference to another metamer, or to an appendage together with the merome or several meromes from that to which the wandering merome belongs in origin. The movement is more usual from behind forwards than in the reverse direction; but this, probably, has no profound significance and depends simply on the fact that, as a rule, the head must be the chief region of development on account of its containing the sense organs and the mouth.

In the Vertebrata the independence of the meromes is more fully developed than in other metamered animals. Not only do we get auto-heterosis of the meromes on a most extensive scale, but the dislocation of single meromes and of whole series (tagmata) of meromes is extremely common. Thus, in fishes the pelvic fins may travel forwards to a thoracic and even jugal position in front of the pectoral fins; the branchiomeres lose all relation to the position of the meromes of muscular, skeletal, coelomic and tegumentary parts; and their vessels may move backwards from their original metameres, in higher vertebrates, carrying nerve-loops with them.
course of the historical development of those various groups of metamized animals, which have undoubtedly sprung from ancestors with more numerous somites than they themselves possess, it appears that we may formulate the following laws as the tenth, eleventh, and twelfth laws of metamorphism.

The Tenth Law is that individual somites tend to atrophy and finally disappear as distinct structures, most readily at the anterior and the posterior ends of the series constituting an animal body. Thus, in the adult, the last somite is comparatively small, and in the larva of many insects there is even no somite. And in the present day, the operation of the law is largely modified by fusion (see below). With regard to the posterior end of the body, the atrophy of segments does not, as a rule, affect the telson itself so much as the somites in front of it, and its power of producing new somites is thus very much reduced. Sometimes, however, the telson is very minute and nonchitinized (Hexapoda).

The Eleventh Law may be stated thus: any somite of the series is capable of becoming somiteless, or one or more of its tagmata may become atrophied, reduced in size or partially ablated by the suppression of some of its meromeres; and finally, such a somite may disappear and leave no obvious trace in the adult structure of its presence in ancestral forms. This is indeed the excitation of a somite. Frequently, however, such "excitated" somites are obvious in the embryo or leave some remnant (e.g. neuromere, muscle or chitinous plate) which can be detected by minute observation (microscopic) as evidence of their former existence. The somite of the maxillipede (third post-oral appendage) of Apis cunctiformis is a good example of a somite on its way to excitation. The third pre-oral and premaxillary somites of Hexapoda in the larva and also the only somite in the lanice somites are furnished by the microscopical study of early embryos. The presegmental somite of the Arachnida is an example of a somite which is preserved in some members of the group and partially or entirely obliterated in other cases, sometimes with fusion of its remnants to neighbouring somites.

The Twelfth Law of metamorphism might very well be placed in logical order as the first. It is the law of lipomorism, and asserts that the bodies of the descendants of unisegmental ancestors, highly metamized forms—i.e. strongly divided forms with specialized regions of differentiated metameres—may gradually lose their metameric structure and become more or less segmentally metameric. The change here contemplated is not the atrophy of terminal segments one by one so as to reduce the size of the animal and leave it finally as a single somite. On the contrary, no loss of segmental structure occurs. But, the whole body is divided equally into two or more metameric units which are widely separated in the body, and their division into two parts is permanent. The animal ceases to present any indication of metamorphic repetition of parts in its entire structure. Degrees in this process are frequently recognized. We certainly can observe such degrees in certain regions of the body of the hermit-crabs and the spiders. Admitting that the Echiurids are descended from Chaetopoda, such a change has taken place in them, amounting to a very slight of complete lipomorism, though not absolutely done.

Recent suggestions as to the origin of the mollusca involve the supposition that such an effacement of once-well-marked metamorphism has occurred in them, leaving its traces only in a few structures such as the many gills and shell-shields of the Clams and the duplicate renal sae of Nautilus. A further matter of importance in this connexion is that when the old metameres have been effaced a new secondary segmentation may arise in the weapon-like body of the degenerate Acanthodorus fuscus.

Such secondary annulation of the soft body-cells to mind the secondary annulation of the metameres of leeches and some earth-worms. In both cases the body of the worm is thrown into an almost infinite number of segments. In the case of the earth-worm, marking the somites of the leech and Lumbricidae in definite number and character are perhaps comparable to the redundant pairs of appendages in the earthworm, and are in the same case, the result of repeated infection of tegumentary meromeres—such a sort of ineffectual attempt to subdivide the somite which only prevails on the more readily susceptible meromeres of the integument.

The last of the laws of metamorphism which we shall attempt to formulate here, the Thirteenth, relates to the fusion or blending of neighbouring somites. Fusion of adjacent somites has often been erroneously interpreted in the study of Arthropoda. There are, in fact, very few cases where this mode of development has been observed. The following generalization may be formulated. "The homologous meromeres of two or more adjacent somites tend to fuse with one another by a blending of their substance. Very generally, but not invariably, the fused meromeres are found as distinct separated structures in the embryo of the animal, in which they unite at a later stage of growth." The fusion of neighbouring somites is often preceded by more or less extensive atrophy of the somites concerned, and by arrest of development in the individual ontogeny. Thus, a case of fusion of partially atrophied somites, and vice versa, incipient merogenesis may be misinterpreted as a case of fusion of separate segments.

A very complete fusion of somites is that seen in the head of Arthropoda, which is a tagma consisting of one, two, or three prothoromeres or somites in front of the mouth and of one, two, three, up to five or six opisthosomites. The cephalic tagma or prosoma may thus be more or less sharply divided into two subtagmata, the pre-oral and the post-oral.

METAMORPHISM (Gr. μετάφημα, change of, and μορφή, shape), in petrology, the alteration of rocks in their structural or mineral characters by which they are transformed into new types. In the history of rock masses changes of many kinds are inevitable. Loose sands, clays and clasts of shells are gradually converted into sandstones, shales and limestones by the action of percolating water and the pressure of over-lying accumulations. All rocks exposed at the earth's surface or terraced by waters circulating through natural fissures, may be assumed to undergo changes in their component minerals due to weathering and the chemical action of the atmosphere and of rain. These processes of cementation and decomposition, though not unlike those of metamorphism, are not regarded as essentially the same. They are considered, so to speak, normal episodes in the history of rocks to which all are subject. When rocks, however, are exposed to the heat of intrusive masses (granite, &c.) or have been compressed, folded, crushed, and more or less completely recrystallized, they assume new characters so different from their original ones that they are ascribed to a quite distinct class, namely, the metamorphic rocks.

The transformation is always gradual, so that in suitable districts every stage can be followed from an unaltered or nearly unaltered sedimentary or igneous rock to a perfectly metamorphic one. The transition may be slow or rapid, and the presence of intermediate forms renders it impossible to lay down any hard and fast lines of distinction. A black shale with fossils may in two or three feet pass into a splintery hornfels; a sandstone or grit becomes a sheared grit, a granulitic gneiss, and a completely recrystallized gneiss sometimes within a few hundred yards; in a thoroughly metamorphic hornblende-schist or chlorite-schist small kernels sometimes occur which can easily be recognized as little modified dolerites or diabases. Still, the metamorphic rocks as a class have many well-defined characteristics, and in perfectly typical development cover enormous areas of the earth's surface and must be, in the aggregate, of vast thickness. A great number of them are recognizable of igneous origin; others are equally certainly sedimentary. Hence some writers have suggested that they are not entitled to rank as a separate class, but only as states or conditions of other rocks. It is generally agreed, however, that the primitive structures and the original minerals of sedimentary or igneous rocks are so transformed as to be no longer easily recognizable the rock should be included in the metamorphic class.

Only rarely, however, does metamorphism produce much difference in the chemical composition of the rocks affected. Sandstones become quartzites and quartz schists, limestones are converted into marbles, granite passes into gneiss, and so on, without their bulk composition being greatly modified. From all that we know it seems established that however great the heat and pressure to which metamorphic rocks have been exposed they have very rarely been melted or reduced to the liquid state. Hence there has been no opportunity for intermixture by solution or diffusion; the changes, including the growth of crystals of new-formed minerals, have gone on in solid rocks, and it is not to be expected that the mineral constituents have aggregated into new combinations and have built up new minerals without travelling for more than infinitesimal distances from the places they occupied in the original rock. Exceptions to this occur, but they are so few that they do not
METAMORPHISM

invalidate the general rule. Thin bands of limestone, for example, may be followed for miles in belts of mica-schist or gneiss, without ever losing their identity by blending with the rocks on either side of them. By tracing out zones such as these it is often possible to unravel the highly complicated stratigraphy of metamorphic regions where the rocks have been greatly folded and displaced. Another important consequence of the persistence of the chemical individuality of metamorphosed rocks is that very often an analysis indicates in the clearest possible fashion what was the original nature of the rock mass. Sandstones, limestones, ironstones, shales, granites, dolerites and serpentines may be totally changed in structure and very completely also in mineral composition, but their chemical characters are practically indelible. Confusion arises sometimes from the fact that two rocks of different origin may have much the same composition, e.g. a felspathic sandstone may closely approach a granite, or an impure dolomite may simulate a basic igneous rock. Individual specimens, consequently, cannot always be relegated with perfect certainty to the sedimentary or igneous rocks; but in dealing with a complex containing a variety of types the geologist is rarely long in doubt as to their original nature.

Two distinct kinds of metamorphism are recognized, namely contact or thermal metamorphism, and folding or regional metamorphism. The former is associated with intrusive masses of molten igneous rock which were injected at a very high temperature and produced extensive changes in the surrounding rocks. The second occurs in districts where earth folding and the movements attendant on the formation of mountain ranges have flexured and crushed the strata, probably at the same time considerably raising their temperature. Although these processes are very different in their origin, and in the great majority of cases produce quite different effects on the rocks, these two phenomena are so closely comparable that a sandstone may be converted into quartzite and a limestone into marble by either kind of metamorphism. It is best, however, to describe them as phenomena essentially different from one another.

Contact Metamorphism (thermo-metamorphism).—Any kind of rock—igneous or sedimentary—which has come in contact with an igneous molten magma is likely to show alteration of this type. The extent and intensity of the changes depend principally on two factors: (1) the nature of the rock concerned, and (2) the magnitude and duration of the heat. It is known that the proximity of granite will produce more extensive effects of this kind than a narrow dike of a few inches or a few feet broad. At the edges of such dikes only a slight induration may be noticeable in the country rock, whereas far in the granite itself there are very great changes. Most rock masses are, however, of intermediate character and the effects are far from pure and hence the variety of minerals which may arise in them from contact alteration is very great. Argillaceous limestones, for example, very frequently contain garnet, vesuvianite, wollastonite, diopside, tremolite, talc, epidote and feldspar; that is to say, minerals in which lime is present along with silica, alumina, magnesia and other substances. Calcareous sandstones yield augite, garnet, sphene, epidote; argillaceous sandstones are characterized rather by biotite, hornblende, chlorite.

In each case the materials already present in the rock have united to form new mineral combinations. Crystallization has been accelerated by the increase in temperature, aided, no doubt, by moisture. Water has a very beneficial effect on the solid state crystallization of minerals and when water pressure is considerable, is a powerful mineralizing agent and greatly facilitates crystallization. Often the rocks acquire ultimately a pseudomorphous or porphyro-blastic structure, as they change character and the new minerals form a ground-mass; not only these porphyritic ingredients but the body of the rock shows increased crystallization, for contact alteration as a rule makes rocks more coarse-grained than before.

The new minerals which are produced differ greatly from the original ones. They fill in the gaps left by the decomposition of the old minerals, and they are sometimes produced in such quantity that they may be mistaken for an entirely new rock. The new minerals which are substituted for the original ones are such as are stable at high temperatures. Many of the silicates which form a large part of sedimentary rocks contain combined water; when heated they lose this water, and if the amount is considerable, the rock itself is expelled, forming silicates with little or no water, e.g. biotite, felspar, andalusite. Carbonic acid may be retained or driven out; in a siliceous limestone the silica tends to combine with the lime producing calc-silicates by replacing the carbonic acid. In a pure limestone the carbonate merely recrystallizes as marble. This loss of volatile ingredients must occasion a diminution in the bulk of the sedimentary mass involved; in cooling there will be contraction, and fissures are produced which may be filled with igneous dikes or with
veins deposited by ascending hot waters. Hence contact aureoles are common sites for mineral deposits of economic value.

In some aureoles the sediments or schists have their bedding and foliation planes wedged apart by the intrusive forces of the granite, and the process is repeated with each successive intrusion. The veins of granite not more than a tenth of an inch in width may be traced, sharply distinct from the slate or schist they penetrate. Cases, however, are described in which the rocks of the aureole have been broken and filled with new felspar derived from the granite; this, however, is not common. Shales are often converted, when in contact with diabase, into pale-coloured, flinty-looking rocks known as adinoles. These are exceptionally rich in barytes and contain much water, and may be closely related to metasomatic rocks formed in shales. It seems probable that alkalis have been transferred from the igneous rock to the sedimentary one, perhaps through the medium of the vapours exhaled. The breadth of the adinole belt is a rule only a few inches or a foot or two.

The vapours given off by intrusive igneous masses may contain substances which combine with the ingredients of the surrounding rocks and thus modify their composition. Boron, fluorine and phosphorus are the principal elements which are transferred into this way, and minerals such as tourmaline, topaz and mica are the characteristic products in quartzite or argillaceous rocks; while apatite, fluor spar, axinite, datolite and chondrodite are common in limestone. This is a form of pneumatolytic action (see Pneumatolysis).

Extreme cases of the mutual interaction of the intrusive rock with the masses invaded by it are provided by the fragments enclosed in the magma, known as xenoliths. These are far more common in coarse and eroded and dissolved. Similar changes are found in the rocks of the aureole for a few feet or yards where in actual contact with the granite. This belt of indurated hornfels, distinguished from the normal schist by the much more slowly than the rest of the country rocks and stands out as a prominent, sharp-edged ridge running round the granite margin. Where sediments are dissolved in igneous rock we may expect to find both chemical and physical changes. The chemical change is in the magma produced on crystallization of the magma. Some granites, for example, which contain many rounded, partly dissolved enclosures of slate are themselves full of corundum, andalusite, cordierite and other minerals. These appear to be due to the action of chemical and physical processes in the igneous body. Egg man has been dissolved in its surroundings. Even in the case of such a simple substance as quartz the difference is marked. The quartz in the country rocks is disseminated and of small size, and is not at all the same kind of quartz as that in the igneous rock which has been altered to change the former character of the country rock. The latter is fine-grained, well sorted, and of the same size and shape as the mineral itself. The fine-grained marginal facies is often porphyritic, while the interior of the mass is granular or eugranular. There is often a tendency to the development of special minerals in the edge of intrusive bodies. This is the case in the diabase dikes, and these are due to the absorption of felspathic material. On the other side it is argued that the changes are due to chemical segregation or differentiation in the magma and not to any admixture with foreign material.

Such modifications in the igneous rock at its contacts are often said to be metamorphic, while those which take place in the aureole or country rocks are exomorphic. The exomorphic changes are not always strictly the nature of contact alteration. The commonest are the presence of a fine-grained, sometimes glassy, chilled edge due to rapid solidification from sudden cooling. The fine-grained marginal facies is often porphyritic, while the interior of the mass is granular or eugranular. There is often a tendency to the development of special minerals in the edge of intrusive bodies. This is the case in the diabase dikes, and these are due to the absorption of felspathic material. On the other side it is argued that the changes are due to chemical segregation or differentiation in the magma and not to any admixture with foreign material.

The metamorphism in a rock series may be of nearly uniform intensity over a large area; the sediments, for example, may have all the characteristics of a metamorphic rock. Where this is the case, although the igneous rocks the porphyritic, opalitic, graphic and other textures may have completely disappeared. This, however, is not always the case, especially when the metamorphism is not of very intense degree. Parts of the rock may retain original structural features, while others are typical crystalline schists and gneisses. Kernels, lumps or phacoids of massive rock are often found embedded in schists, and it is clear upon inspection that the phacoids represent the original rock, while the schist is the effect of metamorphism. At other times a rock mass, such as an intrusive sill, is schistose at its edges and surrounded by schistose sediments, while near its centre it is almost entirely massive. The hard parts of the rock, such as quartz and felspathic fragments, in normal sills and sheets; in folding, the latter have yielded to the stresses, and internal movement has produced foliation. The crystalline rocks in the intrusive sheet have been strong enough to withstand the pressure of the surrounding sediments; and the difference in the degree of differential movement is shown by the presence of a belt of rock which often has a most pronounced schistosity. Some intrusive rocks show foliation especially marked along their edges; or they may be foliated internally according to the plane of internal movement. The latter is characteristic of much massif structure and affects wide tracts of country.

Metamorphic rocks of this kind often cover a large part of a continent (e.g. the centre of Africa or Scandinavia and Finland). Whatever the causes be which produced it, they must have been widespread operation and connected either with great geophysical or geothermal energy, or with the earth's history. Where such rocks occur there is generally much evidence of earth movement accompanied by crushing and folding. They are very characteristic of the central areas of great mountain chains, especially the Andes and Alps, the Pyrenees and the Rhodopes, and are also associated with the Precambrian Shield areas. Most geologists believe that this connexion is causal, holding that the contraction of the outer layers of the earth's crust, due to shrinkage of a nearly rigid shell upon a cooling and contracting core, is the cause of the metamorphism. Where such rocks occur, there is no evidence of any abnormal heat which has been added or rejuvenated, and the recrystallized and largely recrystallized. According to this view, the metamorphism is the result of pressure and folding; hence the name dynamo-metamorphism is frequently applied to it. Such processes of regional metamorphism of the globe may be adduced in support of this hypothesis, forming a mass of evidence so strong as to be almost overwhelming. The structural features which prove that there has been great folding in these rocks are accompanied by microscopic and chemical characters which demonstrate that extensive crushing has taken place. Through progressive stages a slate with fossils may be traced into a phyllite, which becomes a mica-schist, or, in places, a micaceous gneiss. At first the fossils are distorted or torn apart, but they disappear as crystalization advances. Limestones under great pressure and extreme temperatures lose their fossils and become crystalline. Grits, quartzites and slates show the effects of pressure and folding in their structure as they pass down from their evidences of the original clastic or igneous textures, fine slaty mylonites (q.t.) and granulites being produced. Moreover, the degree of metamorphism in the rock can often be shown to correspond to the pressure and temperature.
metamorphism

mass along certain narrow belts; and that recrystallization was set up along with the development of schistose structure. The operating cause cannot have been anything but pressure, especially as the phenomena are not infrequently in lines of dislocation and shear; in other cases they may occur at right angles to the line of the dike, and the transition from massive igneous rock to metamorphic schist may take place within the space of one inch. The best known of phenomena of this order are those described by J. J. J. Teall from the granite gneiss of Scotland.

Where rocks of any kind are traversed by powerful dislocations or fractures they often present a schistose facies in the immediate vicinity of the planes of movement. In the Highlands of Scotland great thrusts occur, in which the rocks are displaced for distances which may be as much as ten miles; and just above or below the adjoining thrust-planes very perfect foliation is induced in all kinds of rocks, sedimentary, igneous or metamorphic, which have been affected. The movement of structure of these rocks is generally of the mylonitic, granulitic or foliated type. In the same way the serpentine of the Lizard in Cornwall passes into fine talcose and tremolitic slabs along narrow zones of displacement, an effect which might be cited from regions where folding and crushing have taken place on a large scale. As a rule, almost without exception, the foliation thus produced is parallel to the direction of movement in the rock mass.

In the mineral transformations which accompany metamorphism the operation of pressure is no less clearly indicated. There are, for example, three minerals which consist of silicate of alumina, viz., feldspar, mica, and amphibole. The last of these has the highest specific gravity. In andalusite or hornblende rocks, which have been sheared, with formation of foliation, we sometimes find pseudomorphs of kyanite after andalusite, retaining the characteristic dimensions of the mineral. Compression, it seems reasonable to suppose, would produce the same effect as the crystals of alumina which has its molecules most closely packed, and consequently the highest specific gravity. This explains the conversion of andalusite into kyanite. The principle that substances tend to assume that form for which their molecular volume is of widest application among metamorphic rocks. It has been calculated, for example, that when olivine and anorthite felspars are sheared, a new feldspar is formed by garnet (a change which takes place not infrequently when basic igneous rocks are subjected to the movement of the molten aggregate diminishes from 145 to 121 or above.)

On the other hand, when garnet is fused it recrystallizes as a mixture of quartz, felspars, and anorthite. This has led to the generalization that all minerals except quartz and the crystalline feldspar, when fused, are converted into the most massive volume which are produced in rocks at temperatures below their fusion points and under great pressures have smaller molecular volumes. Lowelastic changes are usually not so simple a kind as those above enumerated. Mutual interaction may occur between adjacent components of the rocks. Titaniferous iron oxides, for example, obtain silicate and lime from such minerals as augite or lime and feldspar and silt and other minerals. Feldspar often breaks up into a variety of cations, the epidote, quartz and albite; the epidote is formed by iron and magnesium crystals of augite or hornblende. Equations can be written which show the transformation of one rock to another; thus, diabase (laborite) and augite (augite-hornblende) may be converted into amphibolite (acid plagioclase, hornblende and quartz). In this case, the molecular volumes are for diabase 671 and for amphibolite 655-6, indicating a diminution in metamorphism. Many substances, however, are not according to this principle have been added. Caution, however, is required in interpreting the meaning of this if it was always strictly correct the metamorphic rocks should have the same specific gravities as their representatives among sediments and igneous rocks. Very frequently this is not the case, and there must be some compensation for this. In this way it is possible to find this antagonistic principle in the tendency for the minerals of the sediments to contain water of combination, especially epite, muscovite, chlorite, hornblende, talc. This indicates that they were formed at considerable depth.

We arrive then by many independent lines of reasoning (stratigraphical, microscopical, chemical and mineralogical evidence being abundantly available) at the conclusion that pressure acting on sedimentary and igneous rocks at temperatures below their fusion points has been able to change them into metamorphic rocks. This is the theory of dynamo-metamorphism, which has won acceptance from the majority of geologists who have made the petrology of metamorphic rocks their special study. It has, however, many incisive critics, and in recent years dissent has on the whole gained strength.

One of the principal objections is that by these processes it is possible to destroy original structures and to break down the minerals which the water acts upon to induce crystallization and build up rock structures of a new type. It is stated that in many regions the rocks though intensely folded are not highly metamorphic; in other places immense dislocations can be proved which cannot be attributed to the development of metamorphic structures or are converted into fine-grained mylonites and not into typical metamorphosed rocks. Conversely, it is argued, there are many districts where metamorphism is very intense, yet evidence of folding and pressure is called for. It is stated that another factor must be taken into account, and in all probability that factor is temperature. All rocks contain interstitial water, and many also contain minerals in the form of carbonates, and thus in combination. Hence all metamorphism must be regarded as a combination of pressure and temperature. It is almost equally certain that metamorphism must be accompanied by a rise of temperature in nearly every case—in fact it is difficult to account for such a process going on without considerable heat. Now heated rocks of a particular type of rocks, a great increase in pressure and temperature.

The heat required for the more intense stages of metamorphism may be derived from one more source. Most regions of gneiss and schists contain igneous rocks in the form of great intrusive masses which rocks themselves are frequently gneissose, and the possibility must therefore arise that the intrusions which are heated and have been injected into the older rocks at a time when folding was going on, would then be in the region of metamorphism. This would then be partly of the contact type and partly the effect of pressure and movement, "pressure-contact-metamorphism." The contact rocks are those largely affected by the heat of the intrusions, which often contain minerals found in contact zones (andalusite, cordierite, sillimanite, staurolite, &c.), would be produced. Cases are known where this has been very well shown, but many of the rocks may have been strongly heated before the initial movement of the particles must also have generated heat. There are no experimental data to enable us to say what rise of temperature may be produced in this way, but we do not doubt that it was considerable. At the same time that the heat generated may have been conducted away from the surface area as fast as it was produced. If the belt of crushing was narrow, heat would be conducted away into the colder rocks beyond. This may explain why in some rocks there is a considerable amount of grinding down but little crystallization. The heat also may be absorbed by the minerals, which pass through chemical combinations of the endothermal type, but it is not likely that this was used up in this way. With rising temperature the rocks would acquire the greatest importance to this concept, more readily. Then if the heat and crushing ceased, a long period would pass before the temperature gradually fell. The minerals would crystallize in their new peels after the well-known law that these larger particles tend to grow more than the smaller ones, and finally granular aggregates would be replaced by masses of coarser structure. If there has been a considerable rise of temperature we might expect analogous structure and constitution between the folded rocks and such a contact aureole; this has been noted by many geologists.

Another factor which must have been of importance is the depth below the surface at which the rocks lay at the time they were folded. If the depth of the depressions were to increase, the pressures must have been greater, and the escape of the heat generated must have been more rapid. The uppermost members of a complex which was undergoing folding are under the lowest pressures, are at the lowest temperatures and pressure only contain moist moisture. Hence minerals such as epidote, chlorite, sillimanite, staurolite, &c., are often produced by weathering alone, might be expected to produce where the temperatures and pressure are high from the first. This is increased by folding; such minerals as biotite, augite, garnet, feldspar, staurolite, &c., might be produced under these conditions. The earth's crust must be divided into bathymetric zones, each of which was characterized by distinctive types of mineral paragenesis. Some geologists ascribe the greatest importance to this concept, they establish two, three or four, or indeed more different types of metamorphism, each of which belongs to a definite horizon. This is to some extent a resuscitation of the old idea, now discarded, that the Archean rocks are sediments of an ocean floor, but forming before the heated waters of the primordial globe; the first deposits were laid down under great heat and pressure and
METAMORPHOSIS

are typical gneisses which may resemble igneous rocks; the schists of later origin exhibit a progressive transition to normal sediments. Without admitting that it is possible to classify metamorphic rocks according to the depth at which they were situated when metamorphism occurred, it is at least true that the more intense stages of alteration characterize a rule the rock masses which were oldest or most deeply situated during the epoch of folding.

While rocks near the surface which are under comparatively slight pressures yield to stress by fracturing, it is conceivable that at greater depths the minerals would become plastic and suffer deformation without rupture. For this zone of "flowage," as he terms it, van Heerden postulated the idea that during this deformation" on many factors such as the strength of the rocks and nature of the minerals concerned, the temperature, amount of moisture and rapidity of the deformation. Between it and the zone of fracture, which might be likened to the part of a plate which is cracked on the other hand, believes that the depth at which plastic flow begins must be at least 35 kilometres; it is difficult to imagine that rocks which have been so profoundly buried can now be exposed at any point in the crust of the earth.

In the attempt to explain the existence of large masses of metamorphic rocks which are perfectly foliated, but at the same time coarsely crystalline, and show no grinding down of their components, as might be expected on the hypothesis of pure dynamic-metamorphism, F. Becke brought into prominence another principle which may prove to be widely applicable. Although known as Riecke's law, it was advanced many years ago by Sorby. It enunciates that when minerals are subjected to unidirectional pressure acting in a definite direction and not like hydrostatic pressure, equally in all directions) they tend to be dissolved on those sides which face the pressure, while the faces which are not compressed tend to grow by absorption. If a mineral such as a feldspar or mica be brought to an edge, it will be foliated, all having a parallel orientation, and the rock will be schistose, with foliation corresponding in direction to the extension of the mineral plates, and perpendicular to the stresses which were effective during the deformation. This principle of Riecke may be applied to the case where one side and deposit it on the other side are the interstitial moisture and vapours present in the rock. By this means schists and gneisses will be produced, which are perfectly foliated yet have their natural homogeneous and uncrushed. Experimental data are at present wanting to show how far this principle is operative and what its limits, but as a supplementary contribution to the theory of dynamo-metamorphism it has been described as the development of "schistosity by crystallization."

More interesting still are E. Weinschenk's theories of pressure-crystallization and piezo-crystallization (pressure-crystallization). He adduces evidence to show that many gneisses are igneous rocks which were foliated from the first, and a large body of observations in many European countries confirms his statement. In his opinion plutonic igneous rocks under given conditions necessarily assume a banded structure, and contain minerals which are not identical with those of igneous rocks but with the components of schists and gneisses. In the surrounding rocks there is contact alteration, and the minerals are crystallized imperfection, but the newly formed minerals are in a condition differing to a greater or less extent from the adult, and reach the adult state either by a series of small steps or by a more or less considerable metamorphism ("op. cit. ii. 360). Here the term will be used in the sense of the last quotations from Balfour and will be regarded as applicable only to those cases of sudden and marked change which frequently occur at the end of the larval period and sometimes at more or less frequent intervals during its course (Crustacea).

Some authors (see H. G. Bronn, Thierryach, "Myriapoda," Bd 3, Abth. 2, p. 113) have applied the term "metamorphism" only to those cases of larval development in which the young leaves the egg with provisional organs which are lost in the later development. Others apply it to the metamorphosis which the just-hatched young is without provisional organs but differs from the adult in size, and in the number of segments and joints, &c. Such writers apply the term "epimorphosis" when there is merely an alteration of sexual maturity and increase in size after birth or hatching.

The essential feature of metamorphosis is the sudden bursting into function of new organs, whether these organs suddenly arise or have been gradually formed, without becoming functional in preceding larval stages. Another feature of it is the disappearance of organs which have been of use to the larva but which are not required at all or are not required in the same form in the new environment. The term is only used in connexion with larval development and is not applied to the sudden changes, due to a change of environment (e.g. the passage of the mammalian embryo from the oviduct into the uterus), which sometimes occur in embryos. Neither is it used in connexion with the sudden changes which occur at the birth or hatching of an embryo, although, especially, in the case of birth, this event is frequently accompanied by profound morphological alteration.

The most familiar examples of metamorphosis are the abrupt changes which occur at the end of the larval history of the frog and of many insects. In both these cases there is a sudden and great change of environment; there is a sudden demand for new organs which would have been quite useless in the old environment, and organs which were of use in the old environment and are of no use in the new have to be eliminated. The two examples we have chosen have the advantage of showing us the two methods by which the crisis in the life-history is met.

(J. S. F.)
METAMORPHOSIS

In the frog (fig. 1) the structural changes which obtain full fruition at the metamorphosis take place gradually during the previous tadpole life. They relate mainly to the alterations of the respiratory organs and vascular system which are required for the purely terrestrial life of the frog, and to the appearance of the paired limbs. The changes in the respiratory and vascular organs are led up to in the tadpole, which during the greater part of its aquatic life is a truly amphibious animal, breathing by lungs as well as by gills; but a sudden change occurs in these organs at the metamorphosis. The limbs which were slowly formed during tadpole life—the posterior pair visibly, the anterior under cover of the operculum (fig. 1, B)—are of no use to the tadpole and must constitute a pure burden to it. The principal events of the metamorphosis are the sudden appearance of the anterior limbs, and the complete closure of the gill aperture (fig. 1, C). The appearance of the anterior limbs and the acquisition of functional importance by both pairs enable the frog to leave the water and pass on to the land to lead its terrestrial life. The other larval organs, such as the gills and the tail, gradually shrink in size and ultimately vanish. In the case of the gills this shrinkage had begun before the metamorphosis, but the tail shows no sign of diminution until the frog is ready to pass on to the land.

The distinguishing feature of this type of metamorphosis is that the animal is burdened for a certain period, both before and after, with organs which are useless to it. In the next type, which is exemplified by the metabolob Insecta, this occurs to a much smaller extent, although the changes of habitat and the corresponding changes of structure are more remarkable. In insecta the change is usually from a terrestrial or aquatic habitat to an aerial one. The larva of a butterfly is a worm-like organism which creeps on and voraciously devours the foliage of certain plants (fig. 2, C). During its life it undergoes much growth, but no important change in structure. When it leaves the egg it is adapted to live and feed on a particular species of plant, on or near which the eggs are deposited by the parent butterfly. It has powerful biting jaws by which it procures its vegetable food. The adult, on the other hand, is a winged creature which also lives on plants but in quite a different way to the larva (fig. 2, A). It flies from plant to plant and obtains its food by sucking the juices of flowers and other parts. The powerful mandibles of the larva have disappeared and in their place we find a sectorial proboscis formed by the first maxillae [fig. 2, A (4)]. Between the larva and the adult insect there is interposed a resting stage, the so-called pupa (fig. 2, B), during which no food is taken, but very important changes of structure occur. These changes consist of two processes: (1) histolysis, by which most of the larval organs are destroyed by the action of phagocytes; and (2) histogenesis, by which the corresponding organs of the imago are developed from the imaginal disks. The imaginal disks appear to arise in the embryo in which they develop, some of them from the epiblast and some from the hypoblast. They persist practically unchanged through larval life and become active as centres of growth in the pupa. The pupal stage in such a metamorphosis may be compared to a second embryonic stage in which the organs of the adult assume their final shape. In this kind of metamorphosis the larval organs are entirely got rid of in the pupal stage, during which the insect is as a rule incapable of locomotion and takes no food; and the new formation of organs—especially those of locomotion and alimentation—which is necessitated by the totally different habits of the larva and mature insect, is also accomplished at the same period, largely, no doubt, at the expense of the material afforded by the disrupted larval organs. The larva itself does not form any of these organs and carry them about during its active life, though it does possess the very minute centres of growth known as the imaginal disks which burst into activity after the larval life is over. It must not be supposed that in all insects in which the sexual animal has a different habitat from the young form, there is a metamorphosis of the kind just described. In the may-flies and dragon-flies, in which the larva is aquatic, the change is prepared for some time before the actual metamorphosis, the organs which are necessary for the aerial existence being gradually acquired during larval life. In such cases, the metamorphosis belongs to our first type and consists of the act by which the organs previously and gradually acquired suddenly become functional. We have now considered in detail two typical cases of metamorphosis. In the first the change is gradually led up to and the larva is burdened, in its later stages at least, with organs which are of no use to it and only become functional at the metamorphosis. In the other, the change is not led up to. It is sudden, and a kind of second embryonic period is established.
METAMORPHOSIS

only differ in degree and that no line can be drawn between them.

In the Crustacea, as has already been pointed out, many authors apply the term metamorphosis to the whole larval development, which consists of a series of changes leading to the adult form. But this is in our opinion an incorrect use of the word. The typical larval development of a Crustacean consists of a series of small metamorphoses. At each moult new organs which have been developed since the preceding moult become manifest and some of them functional. For instance, the prawn Penaeus leaves the egg as a nauplius larva (fig. 3, A). It issues from the first moult as a metanauplius which has a forked tail, a beginning of the cephalo-thoracic shield, and a large helmet-shaped upper lip. It also possesses stump-like rudiments of the maxillae and two anterior pairs of maxillipeds. After the next moult it is known as a protozoea (fig. 3, B), in which a cephalo-thoracic shield is well developed, the posterior part of the body is prolonged into a tail, in the anterior part of which the thoracic segments are obscurely indicated, and the four pairs of stump-like rudiments have become functional appendages [fig. 3, B (4), (5), (6), (7)]. This passes into a later protozoea stage (C) in which the rudiments of the compound eyes and of the abdominal segments are visible beneath the cuticle and in which certain functional changes (jointing, &c.) have appeared in the limbs. This is succeeded by the zoaea stage (fig. 3, D), characterized by the stalked and functional condition of the eyes, the increased size of the abdominal segments, and the appearance of appendages on the sixth of them, the increase of size in the third pair of maxillipeds (8) which had appeared as small rudiments in the preceding stage, and the appearance of the five pairs of posterior thoracic limbs as small biramous appendages. The zoaea stage is followed by the mysis stage (fig. 3, E) in which the thoracic feet are biramous, as in Mysis. From this the adult form proceeds. The transformation is more gradual than would be gathered from this short description, because molts...
or *Cypris* stage are discernible (fig. 5 (5), (6)) beneath the cuticle. When this is moulted the free-swimming *cypris* larva is liberated with its six pairs of biramous thoracic legs, its bivalve shell, and its paired compound eyes (fig. 6). This is the first metamorphosis. After a certain period of free life the *cypris* larva attaches itself by its anterior antennæ, or to some foreign object and enters upon the pupal stage (fig. 7). During this the larva takes no food and ceases to move, and undergoes important changes of structure and form beneath the larval cuticle, which invests it like a pupal case. These changes lead to the

**METAPHOR**—**METAPHYSICS**

(type, but it is remarkable for the heavy burden of adult structures which the larva, in its later stages at least, carries about (fig. 8).

The adult body is, in the main, fashioned out of the larval body, and it takes over most of the organs of the latter; but as a rule the larval organs, or at least the larval appendages, are not for ever functional, and the adult nervous system of the larva which prevails in the larval locomotory apparatus. In Asteroids and Crinoids the metamorphosis is accomplished by fixation to foreign objects, the larval body being thus transformed into an adult.

In the Vertebrata a metamorphosis occurs in the lamprey and the Amphibia. The metamorphosis of the lamprey is peculiar. It lives for three or four years as a sexless larva, known as the ammocoete, and then, when quite suddenly in the four days before the spawning, it undergoes a series of changes and becomes converted into an adult. The metamorphosis affects the alimentary canal, the eyes, the respiratory apparatus and other organs, and especially the reproductive organs, which become functional only after spawning has occurred. The larval body is therefore described as undergoing "an arrest" during its spawning. In the amphibia the metamorphosis is more gradual and extends over a longer period of time. The larval bodies become simplified, and the adult bodies are transformed by a process of disintegration.

In most cases of metamorphosis the organs of the larva, which are found also in the adult, persist through the transformation, undergoing merely the ordinary modifications of development. But it sometimes happens that such organs are completely destroyed and replaced during the whole process. This is the case in the metamorphosis of the Ichneumonidae, in which all the internal organs undergo disintegration and are reformed. It happens also in nemertine worms which develop by a larva; in these the larval organs are stripped off, and it is often observed that the same phenomenon occurs in sponges. In most Echinoderms a similar phenomenon is observed with regard to the oesophagus and the mouth and anus. The probable explanation of this phenomenon is that the larval organs become so highly specialized in connexion with the larval life that they are unable to undergo further change; new formation is therefore necessary. The phenomenon is one of constant occurrence in the Bryozoa, in which it is usually found in connexion with the larval life, and in which cases there may be no metamorphosis, sometimes even in embryonic development. There can be little doubt that the mouth and anus are both genetically connected with the earlier blastopore and that the blastopore is homologous in most animals; and when, though seldom, does the blastopore become transformed into the adult openings and how various is its fate. The hypothesis suggested above applies completely to this behaviour of the blastopore; that is to say, its the larval mouth or anus, and in some cases to effect.

**METAPHOR** (Gr. μεταφορά, transfer of sense, from μεταφέρω, to carry over), a figure of speech, which consists in the transference to one object of an attribute or name which strictly and literally is not applicable to it, but only figuratively and by analogy. It is thus in essence an emphatic comparison, which if expressed formally is a "simile" (Lat. similia), like; thus it is a metaphorical expression to speak of a ship ploughing her way through the waves, but a simile when it takes the form of "the ship, like a plough, moves," &c. The "simple" metaphor, such as the instance given, becomes the "continued" metaphor when the analogy or similitude is worked out in a series of phrases and expressions based on the primary metaphor; it is in such "continued metaphors" that the soul of the "mixed" metaphor is likely to occur.

**PHYSICS, or METAPHYSICS** (from Gr. μετά, after, φύσις, things of nature, or rather, the natural universe), the accepted name of one of the four great departments of philosophy (q.v.). The term was first applied to one of the treatises of Aristotle, though the arrangement of the Aristotelian canon made by Andronicus of Rhodes, in which it was placed "after the physical treatises" with the description ἀρκοῦν τὰ φυσικά. The term was used not in the modern sense of above or transcending nature (a sense which μετά cannot bear), but simply to convey the idea that the treatise so-called comes "after" the physical treatises. It is therefore nothing more than a literary accident that the term has been applied to that department or discipline of philosophy which deals with first principles. Aristotle himself described the subject matter of the treatise as "First.

1 On the true order of the Aristotelian treatises see ARISTOTLE.
Philosophy" or "Theology," which deals with being as being (Metaph. I, i, κατ' ὑπόθεσιν τής θεωρίας τοῦ ὑπὸ τοῦ καθ' αὑτό). From this phrase is derived the later term "Ontology" (q.v.). The mistake or prehension of the significance of μέτα led to various mistaken uses of the term "metaphysics," e.g. for that which is concerned with the supernatural, not only by the schoolmen but even as late as 17th-century English writers, and within narrower limits the term has been dangerously ambiguous even in the hands of modern philosophers (see below). In the widest sense it may include both the "first philosophy" of Aristotle, and the theory of knowledge (in what sense can there be true knowledge?), i.e. both ontology and epistemology (q.e.), and this is perhaps the most convenient use of the term; Kant, on the other hand, would represent metaphysics as being "nothing more than the inventory of all that is given us by pure reason, systematically arranged" (i.e. epistemology). The earliest "metaphysicians" concerned themselves with the nature of being (ontology), seeking for the unity which they postulated behind the multiplicity of phenomena (see Ionian School of Philosophy and articles on the separate thinkers); later thinkers tended to inquire rather into the nature of knowledge as the necessary pre-requisite of ontological investigation. The extent to which these two attitudes have been combined or separated is discussed in the ensuing article which deals with the various schools of modern metaphysics in relation to the principles of the Aristotelian "first philosophy."  

1. The Science of Being

Side by side with psychology, the science of mind, and with logic, the science of reasoning, metaphysics is tending gradually to reassert its ancient Aristotelian position as the science of being in general. Not long ago, in England at all events, metaphysics was merged in psychology. But with the decline of dogmatic belief and the spread of religious doubt—as the special sciences also grow more general, and the natural sciences become more speculative about matter and force, evolution and teleology—men begin to wonder again about the nature and origin of things; just as it was the decay of polytheism in Greek religion and his own discoveries in natural science which impelled Aristotle to metaphysical questions. There is, however, a certain difference in the way of approaching things. Aristotle emphasized being as being, without always sufficiently asking whether the things whose existence he asserted are really knowable. We, on the contrary, mainly through the influence of Descartes, rather ask what are the things we know, and therefore, some more and some less, come to connect ontology with epistemology, and in consequence come to treat metaphysics in relation to psychology and logic, from which epistemology is an offshoot.

To this pressing question then—What is the world as we know it?—three kinds of definite answers are returned: those of materialism, idealism and realism, according to the emphasis laid by metaphysicians on body, on mind, or on both. Metaphysical materialism is the view that everything known is body or matter; but while according to ancient materialists soul is only another body, according to modern materialists mind without soul is only an attribute or function of body. Metaphysical idealism is the view that everything known is mind, or some mental state or other, which some idealists suppose to require a substantial soul, others not; while all agree that body has no different being apart from mind. Metaphysical realism is the intermediate view that everything known is either body or soul, neither of which alone exhausts the universe of being. Aristotle, the founder of metaphysics as a distinct science, was also the founder of metaphysical realism, and still remains its main authority. His view was that all things are substances, in the sense of at least individuals, each of which has a being of its own different from any other, whereas an attribute has only the being of its substance (Met. Z 1-3; Post. An. i. 4); that bodies in nature are obviously natural substances, and as obviously not the only kind of substance; and that there is supernatural substance, e.g., God, who is an eternal, perfect, living being, thinking, but without matter, and therefore not a body.

At the present day realism is despised on the ground that its differentiation of body and soul, natural and supernatural, ignores the unity of being. Indeed, in order to oppose this unity of being to the realistic duality, both materialists and idealists describe themselves as monists, and call realists dualists by way of disparagement. But we cannot classify metaphysics by the antithesis of monism and dualism without making confusion worse confounded. Not to mention that it has led to another variety, calling itself pluralism, it confuses materialism and idealism. Extremes meet; and those who believe only in body and those who believe only in mind, have an equal right to the equivocal term "monist." Moreover, there is no real opposition between monism and dualism, for there can very well be one kind of being, without being all body or all soul; and as a matter of fact, Aristotelian realism is both a monism of substance and a dualism of body and soul.

It is in many cases unfair to express questions by disparaging terms, and to argue as if the whole choice were between materialistic or idealistic monism, leaving realism out of court. In this case it would also hide the truth of things, which requires two different kinds of substance, body and soul. The strength of materialism consists in recognizing nature without explaining it away, its weakness in its utter inability to explain consciousness either in its nature or in its origin. On the other hand, it is the nature of idealism to emphasize the fact of consciousness, but its vice to exaggerate it, with the consequence of resorting to every kind of paradox to deny the obvious and get rid of difficulties. Thus, in what, in reality, two species of substances, or entirely distinct things, those which are impenetrable, resisting, and those which are conscious substances; and it is impossible to reduce bodies and souls to one another, because resistance is incompatible with the attributes of spirit, and consciousness inexplicable by the attributes of body. So far true metaphysics is a dualism of body and soul. But this very dualism is also monism: both bodies and souls are substances, as Aristotle said; and we can go farther than Aristotle. Men are apt to dwell too much on the co-existence and too little on the inclusiveness of substances. The fact is that many substances are often in one; e.g., many bodies in the one body, and both body and soul in the one substance, of man. So far true metaphysics is a monism of substance, in the sense that all things are substances and that all substances, however different, are members of one substance, the whole universe of body and spirit.

This case metaphysics generally will have to recognize three monisms, a materialist monism of body, an idealistic monism of soul, and a realistic monism of substance, which is also a dualism of substances. But a term so equivocal, leading to an antithesis so misleading as that between monism and dualism, can never represent the real difference between metaphysical schools. We shall return, then, to the clearer and more authoritative division, and proceed to discuss materialism, idealism and realism in their order.

2. Materialism

1. Materialism Proper.—Materialism in its modern sense is the view that all we know is body, of which mind is an attribute or function. Several causes, beginning towards the end of the 18th century, gradually led up to the materialism of M. Schott, Vogt and Büchner, which flourished in the middle of the 19th century. The first cause was the rapid progress of natural science, e.g., the chemistry of Lavoisier, the zoology of Lamarck, the theology of Liebig, and, last but not least, the advances in natural science, which pointed to a unity and gradual evolution in nature, were accompanied by a growth in commerce, manufactures and industrialism; the same kind of spirit showed itself in the revolutionary upheaval of 1848, and in the materialistic publications which immediately followed, while these
publications have reacted on the industrial socialism of our own time. Meanwhile, philosophic forces to counteract materialism were weak. Realism was at a low ebb. Idealism was receding for the moment. Hegelianism had made itself unpopular, and its confusion of God, nature and man had led to differences within the school itself (see Hegel).

These causes, scientific, industrial and philosophical, led to the domination of materialism in the middle of the 19th century in Germany, or rather to its revival; for in its main position, that matter and motion are everything and eternal, it was a repetition of the materialism of the 18th century in France.

Thus Karl Christoph Vogt (q.v.) repeated the saying of the French physician Cabanis, "The brain is determined to thought as the stomach is to digestion, or the liver to the secretion of bile, in the form, 'Thought stands in the same relation to the brain as the bile to the liver or the urine to the kidneys.'" But the new materialism was not mere repetition. J. Moleschott (1822–1893) made a diligent use of the science of his day in his Kreislauf des Lebens (1853). Starting from Lavoisier's discoveries, he held that life is metabolism, a perpetual circulation of matter from the inorganic to the organic world, and back again, and he urged this metabolism against the hypothesis of vital force. Aristotle had imputed to all living beings a soul, though to plants only in the sense of a vegetative, not a sensitive, activity, and in Moleschott's time many scientific men still accepted some sort of vital principle, not exactly soul, yet over and above bodily forces in organisms.

Moleschott, like Lotze, not only resisted the whole hypothesis of a vital principle, but also, on the basis of Lavoisier's discovery that respiration is combustion, argued that the heat so produced is the only force developed in the organism, and that matter therefore rules man. He put the whole materialistic view of the world into the following form: Without matter no force, without force no matter. L. Büchner (q.v.) himself said that he owed to Moleschott the first negative to anatomy, crossing his hands over his heart.

Büchner. — Kraft und Staff (1855), which became a kind of textbook of materialism. Passing from Moleschott to Lyell's view of the evolution of the earth's crust and later to Darwin's theory of natural selection and environment, he reached the general inference, that not God but evolution of matter, is the cause of the order of the world; that life is a combination of matter which in favourable circumstances is spontaneously generated; that there is no vital principle, because all forces, non-vital and vital, are movements; that movement and evolution proceed from life to consciousness; that it is foolish for man to believe that the earth was made for him, in the face of the difficulties he encounters in inhabiting it; that there is no God, no final cause, no immortality, no freedom, no substance of the soul; and that mind, like light or heat, electricity or magnetism, or any other physical fact, is a movement of matter.

Sometimes he spoke of mind as an effect of matter; or, though his expressions may be careless, nothing is made of the difference, for he called it movement and effect indifferently in the same context. His definitely expressed view was that psychic activity is "nothing but a radiation through the cells of the grey substance of the brain of a motion set up by external stimuli." E. Haeckel belongs to a slightly later time than the materialists hitherto mentioned. His book Die Welträtsel (Eng. trans. J. M'Cabe, The Riddle of the Universe) identifies substance with body. Starting like his predecessors with the indestructibility of matter, Haeckel makes more than they do of the conservation of energy, and merges the persistence of matter and energy in one universal law of substance, which, on the ground that body is subject to eternal transformation, is also the universal law of evolution. His strong point consists in inferring the fact of evolution of some sort from the consideration of the facts of organic and inorganic, palaeontology and embryology. On the strength of the consistence of arguments for evolution in the organic world, he carries back the process in the whole world, until he comes to a cosmology which recalls the rash hypotheses of the Presocratics.

He supposes that all organisms have developed from the simple cell, and that this has its origin by spontaneous generation, to explain which he propounds the "carbon-theory," that protoplasm comes from inorganic carbones. He not only agrees with Laplace and Huxley about the evolution of the solar system, but he also agrees with them. In the materialistic assumptions that the affinities, pointed out by Lothar Meyer and Mendeleeff, between groups of chemical elements prove an evolution of these elements from a primitive matter (prothyl) consisting of homogeneous elements; but, however, he does not agree with them that everything, ponderable and imponderable or ether, is evolved from a primitive substance, which condenses first into centres of condensation (pyknatoms), and then into masses, which then make up our sense of gravity, or a dense pyknatom to which everything below it become imponderables. Here he stops; according to him substance is eternal and eternally subject to the law of substance; and God is the eternal force or energy of substance. What, then, is the soul? Is it a product of mind or of matter? Haeckel answers: the latter, because sensation is an inherent property of all substance. He supposes that aesthesis and tropesis, as rudimentary sensation and will, are the very causes of condensation; that they belong to pyknatoms, to ponderables and imponderables, to chemical atoms and molecules. Hence, when he returns to organisms, it does not surprise us that he assigns to ova and spermatozoa cell-souls, to the impregnated ovum germ-soul, to plants tissue-souls, to animals nerve-souls; or that he regards man's body and soul as born together in the impregnated ovum, and gradually evolved from the bodies and souls of lower animals. It appears to his imagination that the affinity of two atoms of hydrogen to one of oxygen, the attraction of two atoms of oxygen to one of nitrogen, and the relative affinity of a pair of lovers are all alike due to sensation and will.

But has Haeckel solved the problems of mind? When he applies sensation and will to nature, and through plants to the lowest animals, he considers their sensation and will to be rudimentary and unconscious. Consciousness, according to his own admission, is not found even in all animals, although it is present not only in the highest vertebrates—men, mammals, birds—but also in ants, spiders, the higher crabs and molluscs. He holds indeed that, in accordance with the law of substance, consciousness must be evolved from unconsciousness with the development of sense organs and a central nervous organ.

At the same time he admits, firstly, that he marks the barrier between unconscious and conscious is difficult; secondly, that it is impossible to trace the first beginning of consciousness in the lower animals; and, thirdly, that "however certain we are of the fact of this natural evolution of consciousness, we are, unfortunately, not yet in a position to enter more deeply into the question" (Riddle of the Universe, 191). Thus in presence of the problem which is the crux of materialism, the origin of consciousness, he first propounds a gratuitous hypothesis that everything has mind, and then gives up the origin of conscious mind after all. He is certain, however, that the law of substance somehow proves that conscious soul is a mere function of brain, that soul is a function of all substances, and that God is the force or energy, or soul or spirit, of nature. He, in fact, returns to a cien t hylozoism (q.v.), which has tended to revive from time to time in the history of thought. He believes that mind and soul are inherent attributes of all bodies. Curiously enough, he supposes that by making mind a universal attribute of matter he has made his philosophy not materialism, but monism. It is really both: monistic, because it reduces substance to one kind; materialistic, because it identifies that one kind of substance with body or matter, and reduces mind to an attribute of matter. It makes no difference to attribute mind to all matter, so long as it is attributed as an attribute. It is at least as materialistic to say that unconscious mind is an attribute of nature as to say that conscious mind is an attribute of brain; and this is the position of Haeckel. Materialists seem to dread the word "materialism." Büchner also entertains us "to abandon the word 'materialism,' to which (it is not clear why) a certain scientific odium attaches, and substitute monism for it" (Last Words on Materialism, 273). His reason, however, is different: it is that a philosophy, not of matter as such, but of the unity of force and matter, is not materialism. But if a monistic philosophy is one which holds that science must do, it will recognize nothing but matter possessing force, and will therefore be materialism as well as monism, and in short materialistic monism. The point is that neither Büchner nor Haeckel could on their assumptions recognize any force but force of
body, or any mind but mind of body, or any distinct thing or substance except body. This is materialism.

2. Materialistic Tendencies.—Besides these direct instances of materialism, there are philosophers to whom the scientific tendencies of the age have given a materialistic tendency. In Germany, for example, Eugen Dühring (q.v.) was a realist, whose intention is to prove against Kant a knowledge of the thing in itself by attributing time, space and categories generally to the real world. But, under the influence of Trendelenburg's attempt to reconcile truth and being by assigning motion to both, his Wirklichkeitstheophilosophie, in a similar effort after a unity of being, lands him in the contention that matter is absolute being, the support of all reality underlying all bodily and mental states. So Avenarius (q.v.) was no materialist, but only an empiricist anxious to reclaim man's natural view of the world from philosophic incrustations, yet when his Empiriokritisimus ends in nothing but environment, nervous system, and statements dependent on them, with a hypothesis of a personal consciousness, he comes near to materialism, as Wundt has remarked. In France, again, positivism is not materialism, but rather the refusal to frame a metaphysical theory. Comte tells us that man first gets over theology, then over metaphysics, and finally rests in positivism. Yet in getting over theology he ceases to believe in God, and in getting over metaphysics he ceases to believe in soul. As Paul Janet truly remarked, positivism contains an unconscious metaphysics in rejecting final causes and an immaterial soul. Now, when in surrendering theology and metaphysics we have also to surrender God and the soul, we are not free from materialism. Positivism, however, shelters itself behind the vague word "phenomena." Lastly, in England we have not only an influence of positivism, but also, what is more important, the synthetic philosophy of Herbert Spencer. The point of this philosophy is not materialism, but realism. The author himself states that "transfigured realism, which is realism in asserting objective existence as separate from subjective existence, but anti-realism in denying that objective existence is to be known. In his Principles of Psychology he twice quotes his point that "what we are conscious of as properties of matter, even down to its weight and resistance, are but subjective affections produced by objective agencies which are unknown and unknowable." This then is his transfigured realism, which, as far as what is known goes, is idealism, but as far as what exists goes, realism—of a sort. His First Principles, his book on metaphysics, is founded on this same point, that what we know is phenomena produced by an unknown noumenal power. He himself identifies phenomenon, appearance, effect or impression produced on consciousness through any of the senses. He divides phenomena into impressions and ideas, vivid and faint, object and subject, non-ego and ego, outer and inner, physical and psychical, matter, all homogeneously to the more heterogeneous, exemplified by the solar system evolving into different bodies; thirdly determination, from the indefinite to the definite, exemplified by the

MATERIALISM] METAPHYSICS 227

He finds that throughout the universe there is an unceasing distribution of matter and motion, and that this distribution constitutes evolution when there is a predominant integration of matter and dissipation of motion, and the reverse of integration and disintegration of matter. He supposes that evolution is primarily integration, from the incoherent to the coherent, exemplified in the solar nebula evolving into the solar system; secondly differentiation, from the more homogeneously to the more heterogeneous, exemplified by the solar system evolving into different bodies; thirdly determination, from the indefinite to the definite, exemplified by the
Spencer's own materialistic definition of evolution; otherwise there will be a break at least between life and mind. If everything knowable is an example of evolution, and evolution is by definition a transformation of matter and motion, then everything knowable is an example of a transformation of matter and motion. As an exponent of universal evolution Haeckel is more consistent than Spencer.

Huxley (1825-1893) developed views very like those of Spencer, and similarly never version of realism, but he chose to be a materialist, because they believe realism, be it ever so "ignorant", is the deepest proof of God; and it cannot be the result of evolution, because it is the condition of natural force, and therefore of natural evolution. A second argument for God is the prevailing goodness or adaptation of Nature to the ends of conscious beings, which might conceivably be explained by Lamarckian evolution, but has not yet been so explained, and if it were, would not be inconsistent with a divine design in evolution. Further, the very existence of conscious beings is the best proof of the distinct or substantial being of the soul, existing in man with body, in God as pure spirit. It seems hopeless to expect that natural science, even with the aid of evolution, can explain by mere body the origin and nature of this fact of consciousness. If so, materialism is not the whole truth of metaphysics.

3.—The Rise of Metaphysical Idealism

1. Descartes to Leibnitz.—Metaphysical arises from psychological idealism, and always retains more or less of an epistemological character. Psychological idealism assumes without proof that we perceive nothing but mental objects, and metaphysical idealism does the logical but hypothetical conclusion that all we can know from these mental objects of sense is mental objects of sense. Some knowledge of this kind was not drawn. Descartes, the founder of psychological idealism, having proceeded from the conscious fact, cogito ergo sum, to the non sequitur that I am a soul, and all a soul can perceive is its ideas, nevertheless went on to the further illogical conclusion that from these mental ideas I can (by the grace of God) infer things which are extended substances or bodies, as well as thinking substances or souls. He was a psychological idealist and a metaphysical realist. This illogicality could not last. Even the Cartesian school, as it came more and more to feel the difficulty of explaining the interaction of body and mind, and, indeed, any efficient causation whatever, gradually tended to the hypothesis that the real cause is God, who, on the occasion of changes in body, causes corresponding changes in mind, and vice versa. This occasionalism is not idealism, but its emphasis on the will of God gave it an idealistic tendency. Thereupon Spinoza advanced a pantheism which supposed that bodies and souls are not, as Descartes thought, different substances, but are merely the one the extension and the other the thought of one substance, Nature or God. Taking the Aristotelian theory that a substance is a thing in itself, not in Aristotle's sense of any individual existing differently from anything else, but in the novel meaning of something existing alone, he concluded, logically enough from this mere misunderstanding, that there can be only one substance, and that, as no finite body or soul can exist alone, everything finite is merely a mode of one of the attributes of the one infinite substance which alone can exist by itself. Spinozism, however, though it tramples down the barrier between body and soul, is not yet metaphysical idealism, because it does not reduce extension to thought, but only says that the same substance is at once extended and thinking—a position more akin to materialism. At the same time Spinoza maintained a parallelism between extension and thinking so close as to say that the order of ideas is the same as the order of things, so that any mode of extension and thought of it is the same thing extended and thought in two ways, under the attribute of extension and under the attribute of thought (see H. H. Joachim's Study of the Ethics of Spinoza, 1901, p. 72).

It remained, however, for Schelling to convert this parallelism into identity by identifying motion with the intelligence of God, and so to transform the pantheism of Spinoza into pantheistic idealism. Leibnitz, again, having become equally dissatisfied with Cartesianism, Spinozism and the Epicurean realism of Gassendi, in the latter part of his life came still nearer than Spinoza to metaphysical idealism in his monadology, or half-Pythagorean, half-Brunistic analysis of bodies into monads, or units, or simple substances, indivisible and unextended, but endowed with perception and appetite.

He gradually fell under the dominion of two false assumptions. On the one hand, essentially a mathematician, he supposed that

unity is indivisibility, whereas everything known to be one is merely undivided or individual, and that there must be simple because there are compound substances, although composition only requires simpler or relatively simple elements. On the other hand, under the influence of the mechanics of Leibnitz, which included the idea that the innate inertia was not or was not distinguished between inertia, or the inability of a body to change itself, and resistance or the ability of bodies to oppose another, he concluded that, as inertia is passive, so is resistance, and refused to recognize the resistance of a body in action as a force, or active power, of changing their movements in opposite directions. From these two arbitrary hypotheses about corporeal motion, that it requires indivisibly simple elements, and that it offers no resistance, he concluded that Leibnitz must be units, or monads, which would be at once substantial, simple, indivisible and active. He further supposed that the monads are "incorpo" and automata, not interacting like bodies, but each perceiving thought in itself, and acting in consequence, by appetite, or self-acting. Such mentally endowed substances might be called souls; but, as he distinguished between perception and apperception or consciousness, and considered that perceptions are substances, between monads and phenomena; and Leibnitz, conscious entelechies of inorganic bodies, sentient souls of animals, and rational souls, or spirits, of men; while he further concluded that all these are derivative monads created by God, the monad of monads. All derivative monads, he allowed, are accompanied by bodies, which, however, are composed of other monads dominated by a central monad. Further, he explained the old Cartesian difficulty of the relation of body and mind by transforming the Spinozistic idea of extensiveness into a lightness, as between the motions of bodies and the perceptions of their monads; motions always proceeding from motions, and perceptions from perceptions; bodies acting according to efficient causes, and souls according to final causes, in the first instance, and as if it influenced the other without actually doing so. He explained the distinction of these two series, as well as that between the perceptions of different monads, by supposing a pre-established harmony ordained by the primitive monad, God.

Up to this point, then, Leibnitz opened one of the chief avenues to metaphysical idealism, the resolution of the material into the immaterial, the analysis of bodies into mental entities. His theory of bodies involved an idealistic analysis neither into bodily atoms nor into mathematical units, but into mentally self-existent simple substances, which he believed to be the trivials of the monads; and he actually supposed the ultimate of everything to be the monads. He, however, made some modification of this theory of the nature of bodies; and here he hesitated between two alternatives. According to one alternative, which consistently flowed from the psychological idealism of Descartes, as well as from his own monadism, he suggested that bodies are real phenomena; phenomena, because they are aggregates of monads, which derive their unity only from appearing together to our perceptions; real phenomena well founded, because they result from real monads. In support of this view, he said that bodies are not substances, though substantia; that their apparent motion and resistance are results of the passions of their monads; that their primary matter is nothing but passive power of their monads; that the series of efficient causes between them is merely phenomenal. According to this alternative, then, there is nothing but mental monads and mental phenomena; and Leibnitz is a metaphysical idealist. According to the other alternative, however, he suggested that at least organic bodies are composed of monads, which are not simple, but are composed of monads; but something realizing or rather substantializing phenomena, or not mere aggregates of monads, but something substantial beyond their monads, because an organic body, though composed of monads, has a real unity (unio rellis).

From this point of view he believed that the real unity of a body is a vinculum substantiale, which gives it its real continuity and is the principle of its actions; that its primary matter is its own principle of resistance; and that it has not only this passive, but also an active, power of its own. He suggested that this theory of the substantial unity of a body might explain substantiation, by supposing that, while the monads and phenomena of bread remain, the vinculum substantiale of the body of Christ is substituted. He feared also whether we can explain the mystery of the Incarnation, and other things, unless real bonds or unions are added to monads and phenomena. According to this alternative, these organic bodies are compound or corporeal substances, which are not monads; and Leibnitz is a metaphysical realist. He was held to this belief in the substantiality of bodies by his Christianity, by the influence of

Aristotle, of scholasticism and of Cartesianism, as well as by his own mechanics. But the strange thing is that at the very end of his life and at the very same time, in 1714-1716, he was writing the idealistic alternative to Remond de Montmort and Dangicourt, and the realistic alternative to Father des Bosses. He must have died in doubt. We cannot, therefore, agree with many recent idealists who regard Leibnitz as one of themselves, though it is true that, when stripped of its realism, his metaphysics easily passed into the metaphysical idealisms of Lotze and of Fechner. It is true, also, that on its idealistic side the philosophy of Leibnitz is the source of many current views of panpsychism, of psychophysical parallelism as well as of the phenomenon of bodies, and of the analysis of bodies into mental elements.

2. Locke to Hume.—Meanwhile in England, Locke, though differing from Descartes about the origin of ideas, followed him in the illogical combination of psychological idealism with metaphysical realism. He thought that we perceive nothing but a mass of primary and of secondary qualities, and yet that somehow we are able to infer that, while our ideas of secondary qualities are not, those of primary qualities are, like the real qualities of external things. Berkeley saw the inconsistency of this position, and, in asserting that all we perceive and all we know is nothing but ideas in "mind, spirit, soul, or myself," has the merit of having made, as Paulsen remarks, "epistemological idealism the basis of metaphysical idealism." According to him, a body such as the sun is my idea, your idea, ideas of other minds, and always an idea of God's mind; and when we have sensible ideas of the sun, what causes them to arise in our different minds is no single physical substance, the sun, but the will of God's spirit. Hume saw that in making all the objects of perception ideas Berkeley had given as little reason for inferring substantial souls as substantial bodies. He therefore concluded that all we know from the data of psychological idealism is impressions or sensations, ideas, and associations of ideas, and these only, and that the way in which causes are united together with "a certain unknown, inexplicable something as the cause of our perceptions." We have here, in this sceptical idealism, the source of the characteristically English form of idealism still to be read in the writings of Mill and Spencer, and still the starting-point of more recent works, such as Pearson's Grammar of Science and James's Principles of Psychology.

3. Kant and Fichte.—Lastly, in Germany, partly influenced by Leibnitz and partly roused by Hume, Kant elaborated his transcendental or critical idealism, which, if not, as he thought, the prolegomena to all future metaphysics, is still the starting-point of most metaphysical idealists.

Kantism consists of four main positions, which it will be well to lay out, as follows:—

a. As to the origin of knowledge, Kant's position is that sense, outer and inner, affected by things in themselves, receives mere sensations or sensible ideas (Vorstellungen) as the matter which sense itself places in the a priori forms of space and time; that thereupon a simple understanding, by means of the synthetic unity of apperception, "I think"—an act of spontaneity beyond sense, in all consciousness one and the same, and combining all my ideas as mine in one universal phenomenon, is constituted; and further, that all the other substantive notions, such as substance and attribute, cause and effect, &c., units groups of sensations or sensible ideas into objects and events, e.g. a house, one ball moving another; and that, accordingly, perceived objects are otherwise only relations or phenomena of the mind, are partly a posteriori and partly a priori, and constitute a knowledge of objects which, being sensations combined by synthetic unity under a priori forms, are more than mere sensations, though less than substances. In this position is contained both psychological idealism in a new form and supported by new reasons; for, if experience derives its matter from mental sensations and its form from mental synthesis of sensations, it can apprehend nothing but objects of the mind, but its ideas of other things are sensible ideas having no existence outside our thought, nothing in themselves; or phenomena, not noumena.

b. As to the known world, Kant's position was the logical deduction that from such phenomena of experience all we can know by logical reason is similar phenomena of actual or possible experience; and therefore that the known world, whether bodily or mental, is not a Cartesian world of bodies and souls, nor a Spinozistic world of one substance, nor a Leibnizian world of metaphysical substances.
created by God, but a world of sensations, such as Hume supposed, only combined, not by association, but by synthetic understanding into phenomenal objects of experience, which are phenomenal substances and causes—a world of phenomena not noumena. A world of sensations, as Hume supposed, is not possible to his form of the synthetic unity of apperception acting by a priori forms, and the supposition, which lies at the foundation of later German philosophy, that since understanding shapes the objects out of sensations, and since nature, as we know it, consists of such objects, "unitedness of a world" does not mean "unitedness of nature" as well as our knowledge. Known nature is a mental construction in part, according to Kant.

c. As to existence, Kant's position is the wholly illogical one that, although all known things are phenomena, there are things in themselves, or noumena; things which are said to cause sensations of outer sense and to receive sensations of inner sense, though they are beyond the category of causality which is defined as one of the notions unifying the phenomena. No grounds are given for asserting the existence of these causal attributes, though declared unknowable by any logical use of reason, because logical reason is limited by the mental matter and form of experience to phenomena; and all this according to Kant himself.

This third position is a relic of ancient metaphysical realism; although it must be remembered that Kant does not go to the length of Descartes and Locke, who supposed that from mere ideas we could know bodies and souls, but suggests that beneath the phenomena of outer and inner sense the thing in itself may not be heterogeneous (ungleichartig). In this form we shall find the thing in itself revived by A. Riehl.

d. As to the use of reason beyond knowledge, Kant's position is that of an immediate inability, in accordance with the transcendental ideas (Ideen), and practical reason, in order to account for moral responsibility, frames postulates of the existence of things in themselves, or noumena, in order to transcend the limits of a thing in its pure, or a priori, use, contains a necessary priori "ideals" (Ideen), and practical reason, in order to account for moral responsibility, postulates the existence of real noumena. But what is a postulate of practical reason to explain moral responsibility except a logical use of reason? Nevertheless, in his own mind Kant's whole speculative and practical philosophy was meant to form one system. In the preface to the second edition of the Kritik he says that it was necessary to limit speculative reason to a knowledge of phenomena, in order to allow practical reason to proceed from morality to the assumption of God, freedom, and immortality, existing beyond phenomena: "Ich musste auch das Wissen aufheben, um zum Glauben Platz zu machen. He forgot that the true end of speculative reason is to transcend itself, and therefore the rationality not only of knowledge, but also of faith.

Fichte now set himself in the Wissenschaftslehre (1794) to make transcendental idealism into a system of metaphysical idealism, without Kant's inconsistencies and reliefs of realism.

Fichte. His point was that there are no things in themselves different from minds or acting on them; that man is no product of things; nor does his thinking arise from passive sensations caused by things; nor is the end of his existence attainable in a world of things; but that he is the absolute free activity constructing his own world, which is only his own determination, his self-imposed limit, and means to his duty which allies him with God. In order to prove this novel conclusion he started afresh from the Cartesian "I think" in the Kantian form of the synthetic unity of apperception acting by a priori categories; but instead of allowing, with all previous metaphysicians, that the Ego passively receives sensations from something different, and not contenting himself with Kant's view that the Ego, by synthetically combining the matter of sensations with a priori forms, partially constructs objects, and therefore Nature as we know it, he boldly asserted that the Ego, in its synthetic unity, entirely constructs things; that its act of spontaneity is not mere synthesis of passive sensations, but construction of sensations into an object within itself; and that therefore understanding makes as well as shapes Nature.

This construction, or self-determination, is what Fichte called positing (setzen). According to him, the Ego posits first itself (thesis); secondly, the non-Ego, the other, opposite to itself (antithesis); and, thirdly, this non-Ego within itself (synthesis), so that all reality is in consciousness. But, he added, as the Ego is not conscious of this self-determining activity, but forgets itself, the non-Ego is posited as the thing within itself, and the Ego as a thing in itself, or per se. Hence it is the office of the theory of knowledge to show that the Ego posits the thing per se as only existing for itself, a noumenon in the sense of a product of its own thinking. This is the definition of the non-Ego as thing in itself, as he determined through the non-Ego—no object, no subject; this is the principal fact about theoretical reason; on the other hand, the Ego posits itself as determining the non-Ego—no subject, no object, the principal fact about practical reason. Hence the united theoretical and practical reason, which Kant had separated, and both with will, which Kant had distinguished; for he held that the Ego, in positing the non-Ego, posits both its own limit and its own act of will as the co-relative limit. The object requires knowledge and the subject requires will. The conclusion of his epistemology is that we start with ourselves positing subjective sensations—e.g., sweet, red—and refer them as accidents to matter in space, which, though mental, is objective, because its production is grounded on a law of all reason.

The metaphysics resulting from this epistemology is that the so-called thing in itself is not a cause of our sensations, but a product of one's own thinking, a determination of the Ego, a thing known to the Ego which constructs it. Fichte thus transformed the transcendental idealism of Kant by identifying the thing with the object; and by interpreting noumenon, not in Kant's sense of something which speculative reason conceives and practical reason postulates but in the Kantian sense of a thing-in-itself, a thing in consciousness, a thing in itself, or product of reason. This change led to another. Kant had said that the synthetic unity "I think" is in all consciousness one and the same, meaning that I am always present to all my ideas. Fichte maintained, however, that the Ego is not even a conscious self, or a common consciousness; and this change enabled him to explain the unity of anything produced by the Ego by contending that it is not the different objects of different thinkers, but the Ego itself that produces unity of a product of one's own. According to Kant, the objective is valid for all consciousnesses; according to Fichte it is valid for one consciousness. Here was the first time grappling with a fundamental difficulty in metaphysical idealism, which is the difficulty of explaining the identity of a thing, e.g., the sun. As long as even the merege realism of the Kantian thing in itself is maintained, the account of there being one-sun is simply that one thing causes all the phenomena of the sun. But as soon as the thing in itself is converted into something mental, metaphysical idealists must either say that there are as many suns as minds, or that there is one mind and therefore one sun. The former was the alternative of Berkeley, the latter of Fichte.

Thus the complete metaphysical idealism of Fichte's Wissenschaftslehre, formed out of the incomplete metaphysical idealism of Kant's Kritik, is the theory on its epistemological side that the Ego is the absolute, and on its non-Ego to infinity without ever completing the process, nor could be even known to exist apart from the moral order which is man's destination. Hence in his Philosophical Journal in 1798 Fichte prefaced a skeptical essay of Forberg by an essay entitled "God, in whom all things consist, is ever and always the moral order; we need no other God, and can comprehend no other." Having, however, in consequence, lost his professorship at Jena, he gradually altered his views, until at length he declared that God is absolute existence, and will set without consciousness and personality; that not mankind but God is absolutely absolute; that we are only its direct manifestations, free but finite spirits destined by God to possess in ourselves the complete shape of the whole thing which is divided into the absolute; that Nature, therefore, is the direct manifestation of man, and only the indirect manifestation of God; and, finally, that being is the divine idea or life, which is the reality of all appearances. His metaphysical idealism was influenced by his disciple, Schelling. Nevertheless, he refused to go as far as Schelling, and could not bring himself to identify either man or nature with Absolute God. He wanted to believe in the absolute without sacrificing personality and freedom. God determines man, and man determines Nature: this is the final outcome of Fichte's pure idealism.

Fichte completed the process from psychological and epistemological to metaphysical idealism, which it has been necessary to
recall from its beginnings in France, England and Germany, in order to understand modern idealism. The assertion of absolute substance by Spinoza incited Schelling and Hegel. The analysis of bodies into immaterial elements by Leibnitz incited Lotze. The Spinozistic parallelism of extension and thought, and the Leibnitzian parallelism of bodily motion and mental action, incited Schelling and Fechner. Berkeley and Hume produced the English idealism of Mill and Spencer, with their successors, and occasioned the German idealism of Kant. Kant's a priori synthesis of sensations into experience lies at the root of all German idealism. But Fichte was the most fertile of all. He carried metaphysical idealism to its height, by not only resolving the body into the mental, but also elevating the action of mind into absolute mental construction; not inferring things in themselves beyond, but originating things from within, mind itself. By changing the meaning of "noumenon" from the thing apprehended (νοούμενον) to the thought (νόμα), and in the hypothesis of a common consciousness, he started the view that a thing is not yours or my thought, but a common thought of all mankind, and led to the wider view of Schelling and Hegel that the world is an absolute thought of infinite mind. In making the essence of mind activity and construction, in destroying the separation of theoretical and practical reason, in asserting that mind thinks things as means to ends of the will, he prepared the way for Schopenhauer and other voluntarists. In making the essence of the Absolute not mere reason, but will, action and life, he anticipated Lotze. In reducing the thing in itself to a thought he projected the neo-Kantism of Lange and Cohen. In the doctrine—no object, no subject—no object, no subject—that is, in the utter identification of things with objects of subjects, he anticipated not only Schelling and Hegel, but also Schuppe and Wundt with their congers. In expanding Kant's act of synthesis till it absorbed the inner sense and the innermost soul, he started the modern paradox that soul is not substance, but subject or activity, a paradox which has been gradually handed down from Schelling and Hegel to Fechner, and from Fechner to Paulsen and Wundt. Meanwhile, through holding with Kant that man is not God, but a free spirit, whose destiny it is to use his intelligence as a means to his duty, he is still the resort of many who vindicate man's independence, freedom, conscience, and power of using nature for his moral purposes, e.g. of Eucken and Münsterberg (qq.e.). Kant and Fichte together became the most potent philosophic influences on European thought in the 19th century, because their emphasis was on man. They made man believe in himself and his mission. They fostered liberty and reform, and even rationalism. They almost avenged man on the astronomers, who had shown that the world is not made for earth, and therefore not for man. Kant half asserted, and Fichte wholly, that Nature is man's own construction. The Kritik and the Wissenschaftslehre belonged to the revolutional epoch of the "Rights of Man," and produced as great a revolution in thought as the French Revolution was in fact. Instead of the old belief that God made the world for man, philosophers began to fall into the pleasing dream, I am everything, and everything is I—and even I am God.

4. NOUmenal IDEALISM IN Germany

Noumenal idealism is the metaphysics of those who suppose that all known things are indeed mental, but not all are phenomenal in the Kantian sense, because a noumenon is knowable so long as by a noumenon we mean some mental being or other which we somehow can discover beyond phenomena. The noumenal idealists of Germany assumed, like all psychological idealists, the unproved hypothesis that there is no sense of body, but there is a sense of sensations; and they usually accepted Kant's point, that to get from such sensations to knowledge there is a synthesis contributing mental elements beyond the mental data of sense. They saw also the logic of Kant's deduction, that all we can know from such mental data and mental categories must also be mental. This was the starting-point of their metaphysical idealism. But they disagreed with Kant, and agreed with Fichte about things in themselves or noumena, and contended that the mental things we know are not mere phenomena of sense, but noumena, precisely because noumena are as mental as phenomena, and therefore can be known from similar data: this was the central point of their noumenal idealism. They rightly revolted against the inconsistencies of Kant's third and fourth positions about the existence of unknown but postulated things in themselves, hidden from theoretical, but revealed to practical, reason. In a way they returned to the wider opinions of Aristotle, which had come down to Descartes and Locke, that reason in going beyond sense knows more things than phenomena; yet they would not hear of external bodies, or of bodies at all. No realists, they came nearer to Spinozistic pantheism and to Leibnizian monadism, but only on their idealistic side; for they would not allow that extension and body are different from thinking and mind. Their real founder was Fichte, on account of his definite reduction of the noumenal to a mental world. This was indeed the very point—the knowability of a noumenal mental world. At the same time it soon appeared that they could not agree among themselves when they came to ask what it is, but in attempting to define it seem to have gone through the whole gamut of mind. Schelling and Hegel thought it was infinite reason; Schopenhauer, unconscious will; Hartmann, unconscious intelligence and will; Lotze, the activity or life of the divine spirit; Fechner, followed by Paulsen, a world of spiritual actualities comprised in the one spiritual actuality, God, in whom we live and move and have our being.

1. Of these noumenal idealisms the earliest in time and the nearest to Fichte's philosophy was the panlogism, begun by Schelling (1775-1854), completed by his disciple Hegel (1770-1831), and then modified by the master himself. Starting from Fichte's "Wissenschaftslehre," Schelling accepted the whole process of mental construction, and the deduction that noumena are knowable products of universal reason, the Absolute Ego. But from the first he was bolder than Fichte in his attributions to God, and he averred that as he thought, is universal reason, and Nature a product of universal reason, a direct manifestation, not of man, but of God. How is this Absolute known? According to Schelling it is known by intellectual intuition. Kant had attributed to God, in distinction from man's understanding, an intellectual intuition of things. Fichte had attributed to man an intellectual intuition of himself as the Absolute Ego. Schelling attributes to man an intellectual intuition of the Absolute God; and as there is, according to him, but one universal reason, the common intelligence of God and man, this intellectual intuition at once gives man an immediate knowledge of God, and identifies man with God himself.

On Schelling's idealistic pantheism, or the hypothesis that there is nothing but one absolute reason identifying the opposites of subjectivity and objectivity, Hegel based his panlogism. But, while he fully recognized his indebtedness to his master, he differed from him profoundly in one fundamental respect. He rightly objected that the system was wanting in logical proof: He rightly, therefore, rejected the supposed intellectual intuition of the Absolute. He rightly contended that, if we are to know anything beyond sense, we must know it by a process of logical reason. But, unfortunately, he did not mean the logical inferences described in the Organon and the Novum organum. He meant a new "speculative" method, dialectic, founded on an assumption which he had already learnt from Schelling, namely, that things which are different but similar can have the same attribute, and therefore be also the same. With this powerful instrument of dialectic in hand, he attempted to show how absolute reason differentiates itself into subjective and objective, ideal and real, and yet is the identity of both—an identity of opposites, as Schelling had said. By the same dialectic Hegel was able to justify the gradual transformation of transcendental into noumenal idealism by Fichte and Schelling. If things different but similar have the same attributes, and are thereby the same, then in the first place the Kantian categories, though thoughts of mental origin and therefore confined to mind, are nevertheless applicable
to things, because things, though different from, are the same as, thoughts, and have the categories of thoughts; in the second place, the Fichtian Ego of mankind is not the Absolute Reason of God, and yet is the same Absolute Reason; in the third place, the Schellingian Nature is the "other" of Spirit, and yet, being a mere reflex of the Idea of Nature, is identical with Spirit; and as this Spirit is everywhere the same in God and men, Nature is also identical with our Spirit, or rather with the Infinite Spirit, or Absolute Reason, which alone exists. The crux of all metaphysical idealism is the difficulty of reconciling the unity of the object with the plurality of subjects. Hegel's assumption of identity in difference at once enabled him to deal with the whole difficulty by holding that different subjects are yet one subject, each of which is obliged to reared from, and identical with, the one subject which is also many. By the rough magic of this modern Prospero the universe of being is not, and yet is, thought, idea, spirit, reason, God. So elastic a solution established a dominant Hegelian school, which is now practically extinct, in Germany, and from Germany spread Hegelianism to France, England, America, and, in fact, diffused it over the civilized world to such an extent that it is still a widespread fashion outside Germany to believe that the world of being is a world of thought.

The plain answer is to contest the whole assumption. Different things, however similar, have only similar attributes, and therefore not the same attributes. If one man's image, and the world in the image of the Divine Idea; but I am not God, and the transitory sun is not the same as God. Of the ideas and realities of things, they are not the same as the Creator and His thoughts. Each is a distinct thing, as Aristotle said. Reality is not reason. It is strange that the utterly assumption of panlegism was not at one contested in this plain way. Nevertheless, objection was taken to the unsatisfactoriness of the system reared upon it. Schelling himself, as soon as he saw his own formulae exposed in the logic or rather dialectic of his disciple, began to reconsider his philosophy of nature; and, in a very same problematical, the conclusions and the method of Hegel. Schelling perceived that Hegel, in reducing everything to infinite mind, absorbed man's free but finite personality in God, and, in declaring that everything real is rational, failed to explain evil and sin: indeed, the lone reader of T. H. Green's Prolegomena to Ethics can see how awkward is the Hegelian transition from "one spiritual principle" to different men's individual freedom of choice between good and evil. Again, Schelling urged that besides the rational element there must be something else; that there is in nature, as natura naturans, a blind impulse, a will without intelligence, which belongs to the absolute; but that even God Himself as the Absolute cannot be pure thought, because thought is not and never was pure idea. He must have existed; and to be merely His thought of it, and therefore pure being is the prior condition of thought and spirit. Hence Schelling objected to the Hegelian dialectic on the ground that, although reason by itself can and must exist either in the subject or in the object, it can only deduce a priori the existence either of God or of Nature, for the apprehension of which experience is required. He now distinguished two philosophies: negative philosophy starting from notions, and positive philosophy starting from being; the former a philosophy of conditions, the latter of causes, i.e. of existence. Hegel, he said, had only supplied the logic of negative philosophy; and it must be confessed that the most which could be extracted from the Hegel will dialectic would be some connexion of thoughts without proving any existence of corresponding things. Schelling was right; but he had too much affinity with Hegelian assumptions, e.g. the panlegistic foundation of things in the notions of reason, to construct a positive philosophy without falling into fresh mysticism, which failed to exorcise the effect of his earlier philosophy of identity in the growing materialism of the age.

2. Meanwhile, by the side of panlegism arose the pantheism of Schopenhauer (1788-1860). This new noumenal idealism began, like the preceding, by combining psychological idealism with the transcendentalism of Kant and Fichte. In Die Welt als Wille und Vorstellung Schopenhauer accepted Kant's position that the world as observable is the "Naturphilosophie"; but he added that the world as noumenal is will (Wille). He got the hint of a notion derived from Kant; but in regarding the noumenal as knowable, because mental, as well as in the emphasis he laid on the activity of will, he resembled Fichte. His theory of the nature of will was his own, and arrived at from a voluntaristic psychology leading to a voluntaristic metaphysics of his own. His psychological starting-point was the unproved assumption that the only force of which we are immediately aware is will; his metaphysical goal was the consistent conclusion that in that case the only force we can know, as the noumenal essence of which all else is phenomenal appearance, is will. But by this noumenal will he did not mean a divine will similar to our rational desire, a will in which an inference and desire of a desirable end and means produces our rational action. He meant an unintelligent, unconscious, restless, endless will. In considering the force of instinct in animals he was obliged to divest will of reason. When he found himself confronted with the blind forces of Nature he was obliged to divest irrational will of feeling. As he resolved this force after another into lower and lower grades of will he asked in what the highest of the grades of will was, and his metaphysics was founded on a misnomer, and simply consisted in calling unconscious force by the name of unconscious will (Unbewusster Wille). This abuse of language brought him back to Leibnitz. But, whereas Leibnitz imputed unconscious perception as well as unconscious appetition to monads, Schopenhauer supposed unconscious will to arise without perception, without feeling, without ideas, and to be the cause of ideas only in us. Hence he rejected the infinite intelligence supposed by Fichte, Schelling and Hegel against whom he urged that blind will produces intelligence, and only becomes conscious in us by using intelligence as a means to ends. He also rejected the optimism of Leibnitz and Hegel, and placed the most irrational of wills at the head of the worst possible worlds (see further Schopenhauer). This pessimistic metaphysics won its way, and procured exponents such as J. Frauenstädt, J. Bahnsen, and, more recently, P. Deussen. The accident of its pessimism attracted F. W. Nietzsche, who afterwards, passing from the philosophy of will to the theory of evolution, ended by imagining that the struggle of the will to live produces the survival of the fittest, that is, the right of the strongest and the will to exercise power, which by means of selection may hereafter issue in a new species of superior man—the Übermenschen. Finally, Schopenhauer's voluntarism has had a profound effect on psychology inside and outside Germany, and to a less degree produced attempts to deduce from voluntaristic psychology new systems of voluntaristic metaphysics, such as those of Paulsen and Wundt.

3. The first to modify the pure voluntarism of Schopenhauer was E. von Hartmann, who (Die Philosophie des Unbewussten, 1869, 1st ed.), advanced the view that the world as noumenal is both unconscious intelligence and unconscious will, thus founding a panpneumatism which forms a sort of reconciliation of the panlegism of Hegel and the panpneumatism of Schopenhauer. In his tract entitled Schelling's positive Philosophie als Einheit von Hegel und Schopenhauer (1869) he further showed that, in his later philosophy, Schelling had already combined reason and will in the Absolute. Indeed, Fichte had previously characterized the life of the Absolute by reason and will without consciousness; and, before Fichte, Leibnitz had already asserted that the elements of Nature are atoms with unconscious perception and appetite. Hartmann has an affinity with all these predecessors, and with Spinoza, with whom he agrees that there is but one substance unaltered by the plurality of individuals which are only its modifications. Following, however, in the footsteps of Schelling, he idealizes the one extended and thinking substance into one mental being; but he thinks that its essence consists in unconscious intelligence and will, of which all individual intelligent wills are only activities. The merit of this fresh noumenal idealism consists in its correction of the one-sidedness of Schopenhauer: intelligence is necessary to will. But Hartmann's criticism does not go far enough. He ends by outdoing the paradox of Schopenhauer, concluding that Nature in itself is intelligent but not conscious, a sort of immanent unconscious God.

As with his master, his reasons for this view are derived, not from a direct proof that unconscious Nature has the mental attributes supposed, but from human psychology and epistemology. Like Leibnitz, he proceeds from the fact that our perceptions are
sometimes conscious, sometimes unconscious, to the inconstant conclusion, that there are beings with nothing but unconscious perceptions; and by a similar non sequitur, because there is the idea of an end in will, he argues that there must be an unconscious idea of an end in matter. He, therefore, in his
problem der Erkenntnisslehre (1889) he uses without proof the hypothesis of psychological idealism, that we perceive psychical effects, to infer with merely hypothetical consistency the conclusion of metaphysical idealism that all we can believe are psychical causes, or something transcendent, beyond phenomena indeed, yet not beyond mind. But, according to him, this transcendent is the unconscious (Krausistes unbewusst Ideales Geschehen). He calls this epistemic "transcendental realism"; "transcendent idealism. On these foundations he builds the
details of his idealistic metaphysics. (a) He identifies matter with mind by identifying atomic force with the striving of unconscious
will, a mistake prevented by Leibnitz and Schopenhauer, who defined causality as logical necessity receiving actuality through will. (b) He contends that, when matter ascends to the evolution
of organic life, the unconscious has a power, over and above its
atmospheric volitions, of introducing a new element, and that in conse-
quence the facts of variation, selection and inheritance, pointed out
by Darwin, are merely means which the unconscious uses for its own ends in morphological development. (c) He explains the rise of
consciousness by supposing that, while it requires brain as a con-
tition, it consists in the emancipation of intelligence from will at the
moment when in sensation the individual mind finds itself with an
idea without will. Here follows his pessimism, like to, but differing from
Kant's. In him there is no consciousness of will, there is no
will, and pain preponderates over pleasure in every individual life,
with no hope for the future, while the final end is not consciousness,
but the painlessness of the unconscious. The truth of Nature is force; the truth of will
will be rational desire; the truth of life is neither the optimism of Leibnitz
and Hegel, nor the pessimism of Schopenhauer and Hartmann, but the
moderation of Aristotle. Life is sweet, and most men have more
unconscious than pains in their lives.

4. Lotze (1817-1881) elaborated a very different noumenal idealism, which perhaps we may express by the name "Pan-
teleology," to express its conclusion that the known
world beyond phenomena is neither absolute thought nor unconscious will, nor the unconscious at all, but the activity of God;
causing in us the system of phenomenal appearances, which we call Nature, or bodies moving in time and space; but being in itself the system of the universal reciprocal actions
of God's infinite spirit, animated by the design of the supreme
good. The Metaphysik of Lotze in its latest form (1879) begins
with a great truth: metaphysics must be the foundation of
psychology. He saw that the theories of the origin of knowledge
in idealistic epistemology are absurd. Like Aristotle, then, he
proceeded to ask the question, What is being? Nevertheless,
he was too much a child of his age to keep things known steadily
before him; having asked the metaphysical question he proceeded
to find a psychological answer in a theory of sensation, which
asserted the mere hypothesis that the being which we ascribe
to things on the evidence of sensation consists in their being
felt. He really accepted, like Kant, the hypothesis of a
sensation which led to the Kantian conclusion that
the Nature we know in time and space is mere sensible appearances in
us. Further, from an early period in his Medicinsche Psychol-
ologie (1852) he reinforced the transcendental idealism of Kant
by a general hypothesis of "local signs," containing the sub-
ordinate hypotheses, that we cannot directly perceive extension
caused by sensation; light and colour; that spatial bodies outside
could not cause in us spatial images, but these images are caused by
but that besides the obvious data of sense, e.g., pressure, heat
and colour, there must be other qualitative different excitations of
different nerve fibres, by means of which, as non-local signs
of localities, the soul constructs in itself an image of extended space containing different places. This hypothesis of an
acquired perception of a space mentally constructed by "local signs" supplied Lotze and many succeeding idealists, including Wundt, with a new argument for metaphysical idealism. Lotze
concluded that we have no more reason for supposing an external space like space constructed out of our perceptions, than we have for supposing an external colour like perceived colour.
Agreeing, then, with Kant that primary qualities are as mental as secondary, he agreed also with Kant that all the Nature
we know as a system of bodies moving in time and space is
sensible phenomena. But while he was in fundamental agree-
ment with the first two positions of Kant, he differed from the
third; he did not believe that the causes of sensible phenomena
can be unknown things in themselves. What then are they?
In answering this question Lotze regarded Leibnitz as his guide.
He accepted the Leibnitzian fallacy that unity is indivisibility,
which led to the Leibnitzian analysis of material bodies into
immaterial monads, indivisible and therefore unextended, and
to the theory of monadic souls and entelechies. Indeed,
from the time of Leibnitz such attempts either to analyse or to con-
struct matter had become a fashion. Lotze agreed with Leibnitz
that the things which cause phenomena are immaterial elements.
but added that they are not simple substances, self-acting, as
Leibnitz thought, or preserving themselves against disturbance,
as Herbart thought, but are interacting modifications of the
one substance of God.

In the first place, he resolved the doubt of Leibnitz about bodies
by supposing entirely against his realistic alternative that an organic
body is a substantia realissima phaenomena, and for his idealistic
alternative that every body is a phenomenon and not a substance at
all. Secondly, he accepted the Leibnitzian hypothesis of immaterial
elements without accepting their self-action. He believed in recipro-
cal action; and the very essence of his metaphysics consists in sub-
limiting the interaction of bodies into the interaction of immaterial
elements, which produce effects on one another and on the soul as
well. Accordin to Lotze, the soul of a body is not a thing in it
self, but it has become a convenient habit to express this
concrete fact in abstract language by calling it the conservation
of space, and the soul of each body is nothing more than the
interaction of the others; as if bodies exchanged motion as men do money.
Now Lotze took this abstract language literally, and had no difficulty
in showing that, as an attribute is not separated from its substance,
the communication of motion does not really take place:
nothing passes. But instead of turning to the concrete fact of the
equivalence of momentum, by which each body moving makes the
other reciprocally act on one another, and even that body's movements
press one another apart in collision. Having thus rejected all bodily
mechanism, he had to suppose that reciprocal action somehow
takes place between immaterial elements. This brought him to
another difference from Leibnitz as well as from Newton. According
to Leibnitz, while each immaterial element is a monadic substance
and self-acting secondary cause, God is the primary cause of all.
According to Lotze, the connexion required by reciprocity figures
also that the whole of every reciprocal action should take place
within one substance; the immaterial elements act on one another
merely as the modifications of that substance interacting within
space. In this way we have here two primary causes, the body and
the soul, or God, in scholastic language a causa im-
manens, or agent of acts remaining within the agent's being.
At this point, having rejected both the Newtonian mechanism of bodily
motion and the Leibnitzian mechanism of reciprocal forces, and
flew to the Spinozistic unity of substance; except that, according
to him, the one substance, God, is not extended at all, and is not
merely thinking, but is a thinking, willing and acting spirit.

Lotze's metaphysics is thus distinguished from the theism
of Newton and Leibnitz by its pantheism, and from the panthe-
ism of Spinoza by its idealism. It is an idealistic pantheism,
which is a denial of all bodily mechanism, a reduction of every-
thing bodily to phenomena, and an assertion that all real action
is the activity of God. At the same time it is a curious attempt
to restore mechanism and reconcile it with teleology by using
mechanism only in a very limited sense, as meaning, according to
which God performs His own reciprocal actions by uniform
laws, which are also means to divine ends. It is also an
attempt to reconcile this divine mechanism with freedom.
In his Mephe Physik (1879), as in his earlier Mikrokosmos (1856-1864),
Lotze vindicated the contingency of freedom by assigning 'to
God a miraculous power of unconditional commencement,
whereby not only at the very beginning but in the course of
nature there may be new beginnings, which are not effects of
previous causes, though once started they produce effects
according to law. Thus his pantheistic is also a teleological
idealism, which in its emphasis on free activity and moral order
recalls Leibnitz and Fichte, but in its emphasis on the infinity
of God has more affinity to Spinoza, Schelling and Hegel.
Hence his philosophy, like the Hegelian, continually torments
one with the difficulty that its sacrifice of the distinct being of

NOUMENAL IDEALISM]
all individual substances to the universality of God entails the sacrifice of the individual personality of men. Our bodies were reduced by Lotze to the general rule of this mental appearance. Our souls he tried to endow with a quasi-existence, arguing that the unity of consciousness requires an indivisible subject, which is distinct from the plurality of the body but interacting with it, is in a way a centre of independent activities, and is so far a substance, or rather able to produce the appearance of a substance. But at the end of his *Metaphysik*, from the conclusion that everything beyond phenomena is divine interaction, he drew the consistent corollary that individual souls are simply actions of the one genuine being. His final view was that certain actions of the divine substance are during consciousness gifted with knowledge of themselves as active centres, but during unconsciousness are non-existent. If so, we are not persons with a permanent being of our own distinct from that of God. But in a philosophy which reduces everything to phenomenal appearance except the self-interacting substance of God, there is no room for either the bodies or the souls of finite substances or human persons.

5. Fechner (1801–1887) affords a conspicuous instance of the idealistic tendency to mystify nature in his Panpsychism, or that form of nouminal idealism which holds that the psychic, spiritual, soul-like nature of animals, of plants, of earth and other planets, of the sun, all embraced as different members in the soul of the world, the highest spirit—God, in whom we live and move and have our being; that the bodily and the spiritual, or the physical and the psychical, are everywhere parallel processes which never meet to interact; but that the difference between them is only a difference between the outer and inner aspects of one identical psychophysical process; and yet that both sides are not equally real, because while psychical and physical are identical, the psychical is what a thing really is as seen from within, the physical is what it appears to be to a spectator outside; or spirit is the self-appearance of matter, matter the appearance of one spirit to another. Fechner's panpsychism has a certain affinity both to Stahl's animism and to the hylozoism of materialists such as Haeckel. But, while it differs from both in denying the reality of body, it differs from the former in extending conscious soul not only to plants, as Stahl did, but to all Nature; and it differs from the latter in the different consequences drawn by materialism and idealism from this universal principle. According to Fechner, spirit is the universal substance, spirit its universal attribute. According to Fechner, spirit is the universal reality, matter the universal appearance of spirit to spirit; and they are identical because spirit is the reality which appears. Hence Fechner describes himself as a twig fallen from Schelling's stem. Schelling's adherent Oken by his *Lehrbuch der Naturphilosophie* conveyed to his mind the life-long impression that God is the universe and Nature God's appearance. At the same time, while accepting the Schellingian parallelistic identity of all things in God, Fechner was restrained by his accurate knowledge of physics from the extravagant construction of Nature, which had failed in the hands of Schelling and Hegel. Besides, he was deeply impressed by the fact of man's personality and by the problem of his personal immortality, which brought him back through Schelling to Leibnitz, whose *Monadologie* throughout maintains the plurality of monadic souls and the omnipresence of perception, sketches in a few sections (§§ 23, 78–81) a panpsychic parallelism, though without identity, between bodily motions and psychic perceptions, a parallelism, however, by the assumption of energy to argue that physical energy pursues its course in bodies without interacting with souls, and that motions produce motions, perceptions produce perceptions. Leibnitz thus influenced Fechner, as in other ways he influenced Lotze. Both, however, used this influence freely; and, whereas Lotze used the Leibnizian argument from indivisibility to deduce indivisible elements and souls, Fechner used the Leibnizian hypotheses of universal perception and parallelism of motions and perceptions, in the light of the Schellingian identification of physical and psychical, to evolve a world-view (Weltansicht) containing something which was neither Leibnitz nor Schelling.

Fechner's first point is his panpsychism. Emphasizing the many real analogies between physical and mental agency, but underrating the much stronger evidences that all the mental operations of men and animals require a nervous system, he flew to the paradox that man is not but limited to man and animal. Fechner was convinced that in addition to the animal, and even the vegetable, the sun, to the earth and other planets, to the universe, there is a panpsychism. In this doctrine of universal animation he was like Schelling; he assumed that the entire area of the world is pervaded by unconscious perceptions, and therefore preferred to call the souls of inorganic beings "Entelechies," Fechner extended consciousness to the whole world; and accordingly, whereas Leibnitz believed in a supramundane Creator of the desus cuiusque viventium, Schelling identified God with the soul of the world. Fechner's second point was that, throughout the animated universe, physical processes accompany psychical processes without interaction. In this panpsychic parallelism he was again like Leibnitz, and he developed his predecessor's view, that the conservation of energy prevents interaction, into the supposition that alongside the physical there is a parallel psychical conservation of energy. Here, again, he went much further than the "ditto, but allow with Schelling, in identifying the physical and the psychical as outer and inner sides of the same process, in which the inner is the real and the outer the apparent. Fechner's third point carried him beyond all his predecessors, connecting the panpsychical idea of the soul with that of the will. It was advanced the ingenious suggestion that, as body is in body and all ultimately in the world-body, so soul is in soul and all ultimately in the world-soul. By this means he explained immortality and vindicated personality. His final point was connected with this panpsychical idea of the soul on the higher sphere of life. It is his so-called "synchronological view" of the soul. Herbert and Lotze, both deeply affected by the Leibnizian hypothesis of indivisible monads, supposed that man's soul is seated at a central point where the animal soul is attached, and that the spirit is necessary to explain the unity of consciousness. Fechner's supposition was that the unity of consciousness belongs to the unity of the whole body; that the seat of the soul is the living body; that the whole soul is a part of the living body; and that the "threshold of consciousness" and that soul is not substance but the single psychical life which has its physical manifestation in the single bodily life. Applying this synchronological view to the soul, and with it the idea of the individual soul in its whole, as here the nature of one's soul is to unite one's little body, so hereafter its essence will be to unite a greater body, while God's spirit unites the whole world by His omnipresence; and he pertinently asked, in opposition to the "ditto, but allow with Schelling, God's soul is the world-view" point. Lastly, the whole of this "world-view" was developed by Fechner in early life, under the influence of his religious training, and out of a pious desire to understand those main truths of Christianity which teach us that we are children of God, that this world is His creation, and that all His works of creation to individual members, we live and move and are in God: "in Deo vivimus, movemus, et sumus." It is important to notice that Fechner maintained this "world-view" in a little book, *Der indeslechte Tod* published in 1848 under the pseudonym of Dr Mises, but which he afterwards republished in his own name in 1866, and again in 1887, as a sketch of his *Weltansicht*. Afterwards in *Vanna* (1848) he discussed the world-view as a knowledge of God and the soul, in the light of the earth and the rest of the world. Then in 1855 he published his *Atomenlehre*, partly founded on his physics, but mainly on his metaphysics. Under the influence of Leibnitz, Boscovich, Kant and Schelling, he maintained that the ultimate particles, the indivisible atoms, which are not bodies, but centres of forces of attraction and repulsion; that impenetrability is a result of repulsive force; and that force itself is only-law—taking as an instance that Newtonian force of repulsion and attraction which we do not understand, and supposing that Newtonian force of repulsion is that process we do understand from the collision of bodies already extended and resisting. But, in thus adapting to his own purposes the Leibnizian analysis of material into immaterial, he drew his *quantitative philosophy* (§§ 120–146). Thus he supposed the supposed forces of force are not Leibnizian "monads" nor Herbartian "reals," nor divine modifications such as Lotze afterwards supposed, but are elements of a system which in other respects resemble the laws of the physics of Leibniz, like that of Lotze, and yet is opposite to the most characteristic feature of monadology—the percipient indivisible monad.

In 1860 appeared Fechner's *Elemente der Psychophysik*, a work which treated the most recent revolutionized metaphysics of body and soul, and of physical and psychological relations generally. It becomes necessary, therefore, to determine
how far Fechner derived his psychophysics from experience, how far from fallacies of inference, from his romantic imagination and from his theosophical metaphysics, which indeed coloured his whole book on psychophysics. At the very outset he started with his previous metaphysics, and derived physical law from geometrical parallels, and that of the soul from pure spirit.

He now compared the spiritual and bodily sides of a man to the concave and convex sides of a circle, as inner and outer sides of the same process, which is psychical as viewed from within and physical as viewed from without, and considered the changes of the physical stimulus, and the psychic and physical and psychic energy do not interfere, but that the psychic is, like a mathematical quantity, a function of the physical, depending upon it, and vice versa, only in the sense that a constant relation according to such a function, that is, the determining stimulus, produces this state of the physical, but not with one ever being cause of the other. By his psychophysics he meant the exact doctrine of the relations of dependency between physical and psychic.

The name was new, but not new to him. While antiquity had applied themselves to determine the relations between the physical and the spiritual called "quality" of sensations. But what was new was the application of this doctrine to the relations between the stimuli and the so-called "intensity" of sensations. He generalized Weber's law (q.v.) to the sensation instead of the stimulus, and by a logarithmic transformation of the stimulus, the stimulus increases in a geometrical ratio; or increases by an addition of the same amount as the former is, and so on. The discovery of the latter is the importance of Weber's and Fechner's law. By the rules of induction from concomitant variations, we are logically bound to infer the realistic conclusion that outer physical stimuli produce the sensations of the inner world, and not the converse, as Kant and his followers believed.

Fechner, the very opposite conclusion followed from the pre-suppositions of his parallelistic metaphysics, and from the Leibnitzian view of the conservation of energy, which he was the first in our time to express with mathematical language. He concluded that a psychical effect, on the ground that physical energy must be exactly replaced by physical energy.

Saying satisfied himself in what he called "outer psychophysics," that the stimulative process in the organism, he proved what he called "inner psychophysics," or the theory of the relation between nervous and psychical processes. He rightly argued against the old theory that the continuity of nervous processes in the brain is interrupted by mental processes of thought and will. The nervous and psychical processes are both psychical, and both the stimulus increases by a constant fraction of the previous stimulus in the nervous system, when Weber's law proves only that it increases by a constant addition of the same amount as the former stimulus. The second question he answered from his parallelistic metaphysics by deducing that even within the organism there is only a constant dependency of sensation on nervous process without causation, because the nervous and psychical processes are not identical, but the sensation psychical. This answer supposed that the whole physical process from the action of the external stimulus on the nervous system to the reaction of the organism on the external world is a series, while the consciousness of the nervous is mere appearance; and so everything, as spirit, left high and dry. What then is the cause of the sensation? Huxley, it will be remembered, in similar circumstances, answered this question by degrading consciousness to an epiphenomenon, or by saying that physical law was against consciousness, and this absurdity, but only to fall into the greater absurdity of his own pancepsychism. Having long assumed that the whole world is animated throughout, and that there are always two parallel series, physical and psychical, he concluded that the sensory stimulus is causing a physical nervous process, a psychical accompaniment of the stimulus is causing the sensation, which, according to him, is the psychical accompaniment of the nervous process; and that, as the whole physical and the whole psychical series are the same, differing only as outer and inner, this identity holds both of stimulus and its psychical accompaniment and of nervous process and its accompanying sensation. Accordingly, he calls these and all other processes "psychophysical"; but they are two parallel series of physical and psychical, differing only as outer and inner, or as aspects of the same energy; he called this "psychophysical energy." In such a philosophy all reality is "psychophysical." At the same time Fechner would not have us suppose that the two sides are equal; accordingly, he calls his physical and psychical metaphysics, but as the psychical is from within, is real, the physical, being the psychical viewed from without, is apparent; so in oneself, though nervous process and psychical process are the same, it is the psychical which is the reality of the nervous. This is a mere appearance; and so everything, as spirit, is the reality, body the appearance of spirit. Finally, he supposed that one spirit is in another, and all in the highest spirit, God. By this means also he explained unconsciousness. In point of fact, many stimuli are beneath the "threshold" of a man's consciousness. Leibniz, in the Nouveaux Essais, i. 11, had also said that "the unconscious is composed of a quantity of "petite perceptions" which we are, not conscious. Proceeding on this suggestion, and misled by the hypothesis of the unconscious, Fechner held that a conscious sensation, like its stimulus, consists of units, or elements, by summation and increments of which conscious sensations and the differences are produced; so that the hypothesis of the unconscious, an auxiliary assumption, arises from an integration of unconscious shocks or tremors. But the hypothesis of the inclusion of spirit in spirit, he was further able to hold that what is unconscious in one spirit is conscious in a higher spirit, while whatever is both conscious of the Spirit's will, and as spirit is, the inclusion of the lower spirits in the higher spirits, is composed, as it were, of the whole world, and this conscious form of the world, the so-called physical world is merely outer appearance of one spirit to another.

Fechner first confused psychophysics and metaphysics in psychophysics, and next proceeded to confuse them again in his work on evolution. (Einige Ideen zur Schöpfungs-und Entwicklungs-geschichte der Organismen, 1873). He perceived that Darwinism attributed too much to accident, and was also powerless to explain the origin of life and the structure of the organism. His own contributions to the development of panpsychism, from which he deduced a "cosmorganic" evolution from a "cosmorganic" or original condition of the world as a living organism into the inorganic, by the principle of tendency to stability. Fechner supposed that the same tendency to stability is a product of the archaic world ("theological" world), the life of the organism, the laws of secondary automatism, while we ourselves are developed from our own mother-earth by differentiation. By thus supposing a psychical basis to evolution, Fechner, anticipating Wundt, substituted a time when the physical no longer produces the "psychical" conception of every act of the organism. The difficulty of such speculations is to prove that things apparently dead and mindless are living souls. Their interest to the metaphysician is their opposition to physics on the one hand and to them on the other. They show us that the greater part of the world is mere body, but that its general adaptability to conscious organisms proves its creation and government by God, and take to the new hypothesis, which, by a transfer of design from God to nature, supposes that everything is alive, and conducts its life by psychical impulses of its own. Fechner himself went even further, and together with design transferred God Himself to nature. This is the subject of his last metaphysical work, Die Tagesansicht gegenuber der Nachtansicht (1879). The "day-view" (Fechner's) is the view that God is the psychical all-embracing being, the law and consciousness of the world. It resembles the views of Hegel and Lotze in its pantheistic tendency. But it does not, we must sacrifice our personality; because, according to Fechner, the one divine concept that unites all things is us in our smaller circles. By this ingenious suggestion of the membership of one spirit in another, Fechner's "day-view" also puts nature in a different position; neither with Hegel sublimating it to the thought of God's mind, nor with Leibniz substituting it to the phenomena of our human minds, but identifying it with the outer appearance of one spirit to another spirit in the highest of spirits.

We have dwelt on this curious metaphysics of Fechner because it contains the master-key to the philosophy of the present moment. When the later reaction to Kant arose against both Hegelianism and materialism, the nearly contemporary appearance of Fechner's Psychophysics began to attract experimental psychologists by its real as well as its apparent exactness, and both psychologists and metaphysicians by its novel way of putting the relations between the physical and the psychical in man and in the world. Fechner saw psychology deriving advantage from the methods, as well as the results, of his experiments, and in 1879 the first psychological laboratory was erected by Wundt at Leipzig. But he had also to endure countless objections to his mathematical statement of Weber's law, to his unnecessary assumption of units of sensation, and to his unjustified transfer of the law from physical to physiological laws of sensation, involving in the opinion his parallelistic view of body and mind. Among psychologists Helmholtz, Mach, Brentano, Hering, Delboeuf, were more or less against him. Sigwart in his Logik has also opposed the parallelistic view; and James has criticized it from the point of view that the soul selects out the possibilities of the brain means to its own ends. Nevertheless, largely under the influence of the exaggeration
of the conservation of energy, many psychologists—Wundt, Paulsen, Riehl, Jodl, Ebbinghaus, Münsterberg, and in England Lewes, Clifford, Romanes, Stout—have accepted Fechner's psychophysical parallelism, as far as at least as men and animals are concerned. Most stop here, but some go with Fechner to the full length of his metaphysical parallelism of the physical and psychical, as psychophysical, throughout the whole world. This influence extended from Germany to Denmark, where it was embraced by Höfding, and to England, where it was accepted by Romanes, and in a more qualified manner as "a working hypothesis" by Stout. But the most thorough and most eloquent of Fechner's metaphysical disciples was F. Paulsen (q.v.), who spread panpsychism far and wide in his Einleitung in die Philosophie.

Here reappear all the characteristic points of Fechner's "worldview"—the panpsychism, the universal parallelism with the identification of physical and psychical, the inclusion of spirit as a principle of the universe, a "day-view" that all reality is spirit, and the appearance of spirit to the self. But Paulsen tries to supply something wanting in Fechner. The originality of Paulsen consists in trying to supply an epistemological foundation of the "day-view" that all reality is spirit, and to solve the "rationalism" of the hypothesis by a hypothesis of the "rationalism." He adsorbing him with Kant and Schopenhauer. He borrows from Kant's "antirealist" the hypothesis of a spontaneous activity of the mind, and from Schopenhauer the conviction that everything we perceive, experience, and know about physical nature, and the bodies of which it consists, is phenomena, and not bodily things in themselves. But he has a different soul, and so does not accept the Kantian conclusion that things in themselves, in the sense of things beyond phenomena, are all unknowable. On the contrary, his contention is that of Fechner—that all knowable things are inner psychological realities—"the outmost and innermost appearing things," and that the soul is symbolized by the visible. Kant, however, had no epistemology for such a contention, because according to him both outer and inner senses give mere appearance, from which we could not know either the things in themselves, or in some. Parting, then, from Kant, Paulsen resorts to a paradox which he shares with Fechner and Wundt. He admits, indeed, Kant's hypothesis that by inner sense we are conscious only of mental states, but he contends that this is a necessary truth. He says, "It is instinct, intuitive feeling, a will to agree with Fechner and Wundt that there is no substantial soul, and that soul is nothing but the mental states, or rather their unity—thus identifying it with Kant's synthetic unity. On this assumption he deduces that in being conscious of our mental states we are conscious of soul not merely as it appears, but as it is itself, and therefore can infer similar souls, other psychical unities, which are also things in themselves.

But is this the essence of this psychical reality which we thus immediately and mediately know? Here he appeals to Schopenhauer's doctrine that will of some sort is the fundamental fact of mental life. Taking, then, will to be the essential thing in itself of which the phenomena are dependent, he has, we think, the psychical things in themselves beyond ourselves are also essentially "wills." Combining with this the central dogma of Fechner that spirit extends throughout the whole of bodily appearance, he concludes that the realities of the world are "wills," that bodies are mere appearances of "wills," and that there is one universal and all-embracing spirit which is "will." His ultimate metaphysics, then, is this: Everything is spirit, and spirit is "will." Lastly, by "will" he does not mean "rational desire,"" will" is instinctive, intuitive feeling, a will to agree with Fechner and Wundt that there is no substantial soul, and that soul is nothing but the mental states, or rather their unity—thus identifying it with Kant's synthetic unity. On this assumption he deduces that in being conscious of our mental states we are conscious of soul not merely as it appears, but as it is itself, and therefore can infer similar souls, other psychical unities, which are also things in themselves.

5.—Phenomenal Idealism in Germany

Phenomenal idealism is the metaphysics which deduces that, as we begin by perceiving nothing but mental phenomena of sense, so all we know at last from these data is also phenomena of sense, actual or possible. So far it is in general agreement not only with Hume, but also with Kant in his first two positions. But it follows Fichte in his revolt against the unknown in itself. On the other hand, as the speculative systems of noumenal idealism, starting from Fichte, succeeded one another, like ghosts who "come like shadows, go depart," without producing conviction, and often in flagrant opposition to the truths of natural science, and when, in consequence, a wave of materialism threatened to submerge mind altogether by reducing it to a function of matter, many philosophers began to despair of the ambitious attempts which had been made to prove that there is a whole world of mind beyond phenomena, as the noumenalists had supposed. They were thrown back on the limits of human knowledge prescribed by Kant, but purged of the unknown thing in itself by Fichte. Phenomenal idealism is the Kantian contention that Nature, as known to science, is phenomena of experience. Unfortunately, the word "phenomenon" is equivocal (see Mind, xiv. 300). Sometimes it is used for any positive fact, as distinguished from its cause. But sometimes also it means what appears, or can appear, to the senses, as distinguished from what does not appear, but can be inferred to exist. Now, Kant and his followers start from his second and narrower meaning, and usually narrow it still more by assuming that what appears to the senses is as mental as the sensation, being undistinguishable from it or from the idea of it, and that an appearance is a mental idea (Vorstellung) of sense; and then they conclude that we can know by inference nothing but such mental appearances, actual and possible, and therefore nothing beyond sensory experience. When, on the other hand, the objects of science are properly described as phenomena, what is meant is not this pittance of sensible appearances, but positive facts of all kinds, whether perceptible or imperceptible, whether capable of being experienced or of being inferred from, beyond, experience, e.g. the farther side of the moon, which is known to exist only by inference. Hence the doctrine of Kant, that Nature as known to science is phenomena, means one thing in Kantism and another thing in science. In the former it means that Nature is mental phenomena, actual and possible, of sensory experience; in the latter it means that Nature is positive facts, either experienced or inferred. It is most important also to notice that Kantism denies, but science asserts, the logical power of reason to infer actual things beyond experience. But the phenomenal idealists have not, any more than Kant, noticed the ambiguity of the term "phenomenon"; they fancy that, in saying that all we know is phenomena in the Kantian sense of mental appearances, they are describing all the positive facts that science knows; and they follow Kant in supposing that there is no logical inference of actual things beyond experience.

1. The Reaction to Kant. The reaction to Kant ("Zurück zu Kant!") was begun by O. Liebmann in Kant und die Epiphenomenismus (1865). Immediately afterwards, in 1866, appeared Lange's Geschichte der Materialismus. In 1871 J. B. Meyer published his Kant's Psychologie. And in 1872 H. Cohen published his most important Kants Theorie der Erfahrung, which led Lange to modify his interpretation of Kant in the second edition of his own book. Lange (a. s.) by his History of Materialism has exercised a profound influence, which is due partly to its apparent success in answering materialism by Kantian arguments, and partly to

Noumenal idealism is not dead in Germany. It died down for a time in the decline of Hegelianism and the rise of materialism. It has since revived. The pure idealism of Fichte is at the bottom of it all. The panlogism of Schelling and Hegel survives in its influence. So still more does the pantheism of Schopenhauer. The three most vital idealisms of this kind at the moment are the panpsychism of Hartmann, combining Hegel with Schopenhauer; the pantheologism of Lotze, reviving Leibniz; and the panpsychism of Paulsen, continuing Fechner, but with the addition of an epistemology combining Kant with Schopenhauer. All these systems of metaphysics, differ as they may, agree that things are known to exist beyond sensible phenomena, but yet are mental realities of some kind. Meanwhile, the natural substances of Aristotelian realism are regarded with common aversion.
its ingenious attempt to give to Kantism itself a consistency, which, however, has only succeeded in producing a new philosophy of Neo-Kantian, differing from Kantism in modifying the a priori and reducing the thing in itself. Lange to some extent modified the transcendentalism of Kant's theory of the origin of knowledge. A priori forms, according to Kant, are contributions of the mental powers of sense, understanding, and reason; but, according to Lange, they are rooted in "the physical-psycho-organizational." This modification was the beginning of a gradual lessening of the antithesis of a priori to a posteriori, until at last the a priori forms of Kant have been transmuted into "auxiliary conceptions," or "postulates of experience." But this modification made no difference to the Kantian and Neo-Kantian deduction from the epistemological to the metaphysical. Lange entirely agreed with Kant that a priori forms can have no validity beyond experience when he says: "Kant is at any rate so far justified as the principle of intuition in space and time in our, and it was a service to all time that he should in this first great example, show what the nature of a priori, just because it arises out of the disposition of our own experience only, can be a posteriori and not a priori." (Hist. of Materialism, trans. E. C. Thomas, ii. 203). Hence he deduced that whatever we know from sensations arranged in such a priori forms are objects of our own experience and mental phenomena. Hence also his answer to materialism. Science, says the materialist, proves that all known things are material phenomena. Yes, rejoins Lange, but Kant has proved that material are merely mental phenomena; so that the more the materialist proves his case the more surely he is playing into the hands of the idealist—an answer which would be complete if it did not turn on the equivocation of the word "phenomenon," which in science means any positive fact, and not a mere appearance, much less a mental appearance, to sense and sensory experience. Having, however, made a deduction, which is at all events consistent, that on Kantian assumptions all we know is mental phenomena. Lange proceeded to reduce the rest of Kantism to consistency. But his ardent love of consistency led him far away from Kant in the end; for he proceeded consistently from the assumption that Kant's a priori is ideal, to the logical conclusion that in practical matters our moral responsibility cannot prove the reality of a noumenal freedom, because, as on Kant's assumption we know ourselves from inner sense only as phenomena, we can prove only our phenomenal freedom. Lange thus transmuted inconsistent Kantism into a consistent Neo-Kantianism, consisting of these reformulated positions: (1) we start with sensations in a priori forms; (2) all things known from these data are mental phenomena of experience; (3) everything beyond is idea, without any corresponding reality being knowable. "The intelligible world," he concluded, "is a world of poetry." Our reflection is that there is a great difference between the essence and the consistency of Kant's philosophy. Its essence, as stated by Kant, was to reduce the logical use of reason to mental phenomena of experience in speculation, in order to extend the practical use of reason to the real noumena, or things in themselves, required for morality. Its consistency, as deduced by Lange, was to reduce all use of reason, speculation, to its logical use of reason, leaving the mental phenomena of experience, and further, arranged a priori, to mental phenomena of experience, beyond which we can conceive ideas but postulate nothing. As H. Vaihinger, himself a profound Kantian of the new school, says: "Critical scepticism is the proper result of the Kantian theory of knowledge." Beyond phenomena, and "critical monism," so far as it holds that these things are unlike both physical and psychical phenomena, but are nevertheless the common basis of both. He accepts the Kantian positions that unity of consciousness combines sensations by a mental act, and that our consciousness never is enough about matter moving in space is merely phenomena of outer sense; and he agrees with Kant that from these data we could not infer things in themselves by reason. But his point is that the very conception of phenomena implies the things which appear. "Sensory knowledge," he says, "is the knowledge of the relations of things through the relations of the sensations of things." Further, holding that, "like every other perception, the perception of the basis of vision, of body immediately before the body," and, like Fichte, believing in "a common consciousness," he concludes that the evidence of sense is verified by "common consciousness of the external world as objective in the Kantian sense of universally valid. He interprets the external world to be the common basis of physical and psychical phenomena. He relies on the numerous passages, neglected by Lange, in which Kant regards things in themselves as neither phenomena nor ideas, but things existing beyond both. But his main reliance is on the "noumenon" of the Critik, where Kant, speaking of the Cartesian difficulties of communication between body and soul, suggests that, however body and soul appear to be different in the phenomena of outer and inner sense, what lies as thing in itself at the basis of the phenomena of both may be not so heterogeneous (sensible/sensible) after all. Riehl elaborates this bare suggestion into the metaphysical theory that the single basis of physical and psychical phenomena is neither bodily nor mental, nor yet space and motion. In order to explain that we can put this into a form that will explain the extent of the psychophysical philosophy of Fechner. He agrees with Fechner that physical process of nerve and psychical process of mind are really the same psychophysical process as appearing in different ways as a mental and an external phenomenon of consciousness; and that physical phenomena only produce physical phenomena, so that those materialists and realists are wrong who say that physical stimuli produce sensations. But whereas Fechner recognizes that the physical body is only the appearance that has been complicated by psychical processes which are the real causes of the sensations, Riehl rejects this paradox of universal parallelism in order to fall into the equally paradoxical hypothesis that something other than the mind is a necessary condition with the physical phenomena of matter moving in space and the psychical phenomena of mind to arise in us as its common effects. In supposing a direct perception of such a non-descript thing, he shows to what straits idealists are driven in the endeavour to supplement Kant's limitation of knowledge to phenomena by some sort of knowledge of things.

2. The Reaction to Hume.—When the Neo-Kantians, led by Lange, had modified Kant's hypothesis of a priori forms, and retracted Kant's admission and postulation of things in themselves beyond phenomena and ideas, and that too without proceeding further in the direction of Fichte and the noumenal idealists, there was not enough left of Kant to distinguish him essentially from Hume. For what does it matter to metaphysics whether by association sensations suggest ideas, and what give rise to ideas of substance and causation a priori, or synthetic unity of consciousness combines sensations by a priori notions of substance and causation into objects which are merely mental phenomena of experience, when it is at once allowed by the followers of Hume and Kant alike that reason in any logical use has no power of inferring things beyond the experience of the reasoner? In either case, the effective power of inference, which has been reduced to a posteriori, was the reaction to Kant was followed by a second reaction to Hume, partly under the name of "Positivism," which has attracted a number of adherents, such as C. Göring (1841-1870), author of an incomplete System der Kritischen Philosophie (1874-1875) and E. Laas (p.s.), and partly under the name of the "physical phenomenology" of E. Mach. Ernst Mach (p.s.) is a conspicuous instance of a confusion of physics and psychology ending in a scepticism like that of Hume. He tells us how from his youth he pursued physical and psychological studies, how at the age of fifteen he read Kant's Prolegomena, and later rejected the thing in itself, and came to the conclusion that the world with his ego is one mass of sensations. For a time, under the influence of Fechner's Psychophysik, he thought that Nature has two sides, a physical and a psychological, and added that all atoms have feeling. But in the progress of his physical work, which taught him, as he thought, to distinguish between what we see and what we
mentally supply, he soon passed from this noumenalism to a "universal physical phenomenology." It retains some relics of Fechner's influence; first, the theory of identity, according to which the difference between the physical and psychical is not a dualism, but everything is at once both; and secondly, the substitution of mathematical dependence for physical causality, except that, whereas Fechner only denied causality between physical and psychical, Mach rejects the entire distinction between causality and dependence, on the ground that "the law of causality simply asserts that the phenomena of Nature are dependent on one another." He comes near to Hume's substitution of succession of phenomena for real causality. He holds, like Hume, that nothing is real except our sensations and complexes of sensory elements; that the ego is not a definite, unalterable, sharply bounded unity, but its continuity alone is important; and that we know no real causes at all, much less real causes of our sensations; or, as he expresses it, bodies do not produce sensations, but complexes of sensations form bodies. If he has any originality, it consists in substituting for the association of ideas the "economy of thinking," by which he means that all the theoretical conceptions of physics, such as atoms, molecules, energy, &c., are mere helps to facilitate our consideration of things. But he limits this power of mind beyond sensations to mere ideas, and like Hume, and, so once more, Lange, he asserts that we know no more than the inner forms of sensation, or phenomena, we cannot know things. If we ask how Mach arrived at this scepticism, which is contained in his well-known scientific work Die Mechanik in ihrer Entwicklung (1883; ed. 1908) as well as in his psychological work on the Analysis of Sensations (Beitrag zur Analyse der Empfindungen, 1886), we find two main causes, both psychological and epistemological; namely, his views on sense and on inference. In the first place, he displays in its most naked form the common but unproved idealistic paradox of a sense of sensations, according to which touch apprehends not pressure but a sensation of pressure, sight apprehends not colour but a sensation of colour, and there is no difference between the sensory operation and the sensible object apprehended by any sense, even within the sentient organism. Hence, according to him, sensations are not apprehensions of sensible objects (e.g. pressures felt) from which we infer similar objects beyond sense (e.g. similar pressures of outside things), but are the actual elements out of which everything known is made; as if sensations were like chemical elements. Within the limits of these supposed sensory elements, Mach finds more than many psychologists do to sense: because, following the nativists, Johannes Müller and Hering, he includes sensations of time and space, which, however, are not to be regarded as "pure intuitions" in the style of Kant. But here again he identifies time and space with the sensations of them (Zeitempfindungen and Raumempfindungen). On the assumption, then, that time and space are not objects, but systems, of sensations, he concludes that a body in time and space is "a relatively constant sum of touch-and-light-sensations, joined to the same time-and-space-sensations," that each man's own body is included in his sensations, and that to explain sensations by motions would only be to explain one set of sensations from another. In short, sensations are elements and bodies complexes of these elements. Secondly, his theory of inference contains the admission that we infer beyond sensations: he remarks that the space of the geometer is beyond space-sensations, and the time of the physicist does not coincide with time-sensations, because it uses measurements such as the rotation of the earth and the vibrations of the pendulum. But by inference beyond sense he does not mean a process of concluding from sensations to other similar sensations, e.g. from tangential pressures to other similar pressures in the external world. Inference, according to him, is merely mental completion of sensations; and this mental completion has two characteristics: it only forms ideas, and it proceeds by an "economy of thought." In the course of his learned studies on the history of mechanics he became deeply impressed with Galileo's appeals to simplicity as a test of truth, and converted what is at best only one characteristic of thinking into its essence. According to him, whatever inferences we make, certain or uncertain, are mere economies of thought, adapting ideas to sensations, and filling up the gaps of experience by ideas; whatever we infer, whether bodies, or molecules, or atoms, or space of more than three dimensions, are all without distinction equally provisional conceptions, things of thought; and "bodies or things are comendous mental symbols for groups of sensations—symbols which do not exist outside thought." Moreover, he applies the same scepticism to cause and effect. "In Nature," says he, "there is no cause and no effect." He thinks that repetitions of similar conjunctions occur in Nature, the connexion of cause and effect only in abstraction. He refers to Hume as recognizing no causality but only a customary and habitual succession, but adds that Kant rightly recognizes that mere observation cannot teach the necessity of the conjunction. But in reality his theory is neither Hume's theory of association nor Kant's of an a priori notion of understanding under which a given case is subsumed. He thinks that there is a notion of understanding (Versandesbegriff), under which every new experience is subsumed, but that it has been developed by former experience, instinctively, and by the development of the race, as part of the economy of thinking. "Cause and effect are therefore implied in the things themselves, the thought-things of reality [Gedankendinge von ikonomischen Function]." His philosophy, therefore, is that all known things are sensations and complexes of sensory elements, supplemented by an economy of thinking which cannot carry us beyond ideas to real things, or beyond relations of dependency to real causes.

It is important to understand that Mach had developed this economical view of thought in 1872, more than ten years before the appearance of his work on the history of mechanics as he tells us in the preface, where he adds that at a later date similar views were expressed by Kirchhoff in his Vorlesungen über mathematische Physik (1874). Kirchhoff asserted that the whole object of mechanics is "to describe the motions occurring in Nature completely in the simplest manner." This view involves the denial of force as a cause, and the assertion that all we know about force is that the acceleration of one mass depends on that of another, as in mathematics a function depends on a variable; and that even Newton's third law of motion is merely a description of the fact that two material points determine in one another, without reciprocally causing, opposite accelerations. It is evident that Kirchhoff's descriptive is the same as Mach's analytical. That is, in fact, Kirchhoff's statement "if a body A exerts a force on a body B, I mean that on, coming into contra-
position with A, is immediately affected by a certain acceleration with respect to A." In a word, Mach and Kirchhoff agree that force is not a cause, convert Newtonian reciprocal action into mere interdependence, and, in old terminology, reduce mechanics from a natural philosophy of causes to a natural history of mere facts. Now, Mach applies these preconceived opinions to "mechanics in its development," with the result that, though he shows much skill in mathematical mechanics, he misrepresents its development precisely at the critical point of the discovery of Newton's third law of motion.

The true order of discovery, however, was as follows:—

(a) Sir Christopher Wren made many experiments before the Royal Society of London, which were recorded for by Sir Isaac Newton in the Principia, experimentally proving that bodies of ascertained comparative weights, when suspended and impelled against one another, forced one another back by impressing on the opposite changes of momentum inversely as their weights and therefore masses; that is, by impressing on one another equal and opposite changes of momentum.

(b) Wallis showed that such bodies reduce one another to a joint motion of equality, which were the same as the common velocity of the bodies, that is, deducible from the fact that their common centre of gravity, which is the same as the common velocity of the bodies, that is, deducible from the fact that their common centre
of gravity does not change its state of motion or rest by the actions of the bodies between themselves; and they further extended the law to bodies, qua elastic.

(d) Hence, first inductively and then deductively, the third law was discovered only as a law of collision or impact between bodies of ascertained weights and therefore masses, impressing on one another equal and opposite changes of momentum, and always reducing one another to a joint mass with a common velocity to begin with, which is the essence of elastic inaction.

(e) Newton in the *Principia*, repeating and correcting Wren's experiments on collision, and adding further instances from attractive forces of magnetism and gravity, induced the third law of motion as a general law of nature.

This order of discovery shows that the third law was generalized from the experiments of Wren on bodies of ascertained comparative weights or masses, which are not material points or mass-points. It should be impressed on us that the third law is a law of mutual attraction or repulsion, and that the evidence of the third law disappears; for in the case of attractive forces we know nothing of their *modus operandi* except by the analogy of similar forces known, and we are not able to believe that something similar, we know not what, takes place in gravity, magnetism, electricity, &c. Now, Mach, though he occasionally drops hints that the discovery of the law of collision constitutes a new science, consistently maintains, a comparison of the first law of motion with the third law of motion. On the contrary, he treats the laws of collision with other laws as an application of the third law of motion, because it is now unfortunately so taught in books of mechanics. He supposes that a system of bodies, which are assumed to be extended, mutually impenetrable substances, and by this force causes which reduce one another to a joint mass with a common velocity on collision, as for instance in the ballistic pendulum; these are the reciprocal causes of the common velocity of their joint mass, whatever happens afterwards. In the case of this one force we know far more than the interdependence supposed by Mach and Kirchhoff; we know bodies with impenetrable force causing another one to know it. It might have been expected that scepticism on this subject would not have had much effect. But the idealists are only too glad to get any excuse for denying bodily substances and causes; and, while Leibnitz supposed them away in order to make his metaphysics and the transcendentalism of Hume with the reduction of bodies to assemblages of sensations, Mach adds the additional argument that bodily forces are not causes at all. In Great Britain Mach's scepticism was welcomed by Karl Fries, and Fries's idealism was pessimistic, like Mach's; and by Ward to support a nominalism derived from Lotze. No real advance in metaphysics can take place, and natural science itself is in some danger, until the true history of the evidences of the laws of the third law are restored; and both forces we neglect that in the law of force of collision what we know is not material points determining one another’s opposite accelerations, but bodies by force of impenetrable pressure causing one another to keep apart. Mechanics is a natural philosophy.

3. *Dualism within Experience.*—Besides those philosophies which are reactions to Kant or to Hume, there are a number of other modern systems which start with the common hypothesis that knowledge is experience. The consequence is that whatever is true of experience they transfer to all knowledge. One of the characteristics of actual experience is that its object is, or has been, present to an experiencing subject; and of possible experience that it can be present. As a matter of fact, this characteristic differentiates experience from inference. By inference we know that things, such as the farther side of the moon, which neither are, nor have been, nor can be, present to an experiencing subject on the earth, nevertheless exist. But, on the hypothesis that knowledge contains no inferences beyond experience, it follows that all the objects of knowledge, being objects of experience, are, or have been, or can be, present to an experiencing subject, and hence it is common nowadays to hold that there is indeed a difference between knower and known, ego and non-ego, subject and object, but that they are inseparable; or that all known things are objects and subjects inseparably connected in experience. This view, however, is held in different forms; and two opposite forms have arisen in Germany, "immanent philosophy" and "empirio-criticism," the former nearer to Kant, the latter to Hume.

Immanent Philosophy is the hypothesis that the world is not an object of knowledge, but is manifest in it, and is the common object of all knowledge. Among the upholders of this view are, among the followers of Leibnitz, *Immanent Philosophy* and "empirio-criticism," the former nearer to Kant, the latter to Hume.
"originally accepts over against him an environment with manifold parts, other individuals making manifold statements, and what is stated in some way dependent upon the environment." Statements dependent upon the environment are what he means by pure explanations, which are the same as dualistic explanations but in reality the author only meant dualism within experience. By the environment he meant not a thing existing in itself, but only a counterpart (Gegengelt) of ourselves as central part (Centralgelt)." We cannot," he adds, "think ourselves as central part away. He is perhaps right. At some time there was no living being in the whole, one means that there was besides oneself no other central part to whom one's counterparts might also be counterparts. The consequence is that all the statements admitted into his philosophy of the environment (empirico-critical essential co-ordination) (empirico-kritische Prinzipialkoordination), an inseparable correlation of central part and counterpart, eg and environment. Within this essential co-ordination of experience, the reality of the existent as stimulus; C-values of the central nervous system; and E-values of human statements—the latter being characterized by that which at the time of its existence for the individual admits of being named, and including what we call sensations, &c., which depend indirectly on the environment and directly on the central part but not, as the materialist supposes, in any way reducible to possessions of the brain or any other part of that system. This division of values brings us to the second point in his philosophy, his attempt, secondarily, at least, to explain life, action and thought. A vital series he supposed to be always a reaction of C against disturbance by R, consisting in the first a vital difference, or diminution by R of the maintenance-value of C for the production of his maintenance-value of its former composition. He then proceeds to the third and fourth points, that, while this independent vital series of C is sometimes of this simple kind, at other times it is complicated by the addition of a dependent vital series of C against disturbance by R, and in almost every fetched explanations, he endeavoured to explain conscious action and thought. (Thus, if a pain is an E-value directly dependent on a disturbance in R, and a pleasure another E-value directly dependent on a recovery of C, it will follow that a transition from pain to pleasure is a change in the distribution of C-values in a dependent vital series of C, recovering from a vital difference to its maintenance-maximum.) Lastly, supposing that all human processes can in this way be reduced to vital series in an essential co-ordination of central part and environment, Avenarius held that this empirico-critical supposition, which according to him is also the natural view of pure experiences, contains no opposition of physical and psychical, an outer physical and an inner psychical world—an opposition which science has therefore to discharge in dependence on the supposition that the whole hypothesis that an outer physical thing causes a change in one's central nervous system, which again causes another change in one's inner psychical system or soul, is a departure from the empirico-critical hypothesis. "The free will, the projective faculty, of man," he says, "is a projective principle which encloses soul and faculties in the body, and then, having created a false antithesis between outer and inner, gets into the difficulty of explaining how an outer physical stimulus can impart something into an inner psychical soul. He cannot escape this difficulty, for his hypothesis of causation is our hypothesis of causation, and from the hypothesis of causation, we ought to return to the view of reality as an essential co-ordination of eg and environment, of central part and counterpart, with R-values, C-values and E-values.

It is curious that Avenarius should have brought forward this artificial hypothesis as the natural view of the world, without reflecting that on the one hand the majority of mankind believes that the environment (R) exists, and will exist, without being as central part (C) and that on the other hand it is so far from being natural to man to believe that sensation and thought (E) are different from, and merely dependent on, his body (C), that throughout the Homeric poems, though soul (E) is mentioned, in the use for its own ends a purely intellectual act, is regarded as a purely bodily operation. It is indeed difficult to assign any rational place to the empirico-criticism of Avenarius. It is materialistic without being materialism; it is realistic without being realism. Its rejection of the whole relation of physical and psychical systems, and the substitution of two less complex systems, is a disturbing feature for philosophical systems. But its main point is the essential co-ordination of ego and environment, as central part and counterpart, in experience. It is therefore nearly connected with "immanent philosophy." Schopenhauer assumes an essential co-ordination of ego and environment, as central part and counterpart, in experience. At the same time Schuppe's hypothesis of one common consciousness uniting the given by a priori categories could hardly be accepted by Avenarius as purely naturalistic. Whether all the "world's work" is empirical criticism, is idealistic dualism within experience in an posteriori form, but with a tendency towards materialism.

Voluntaristic Phenomenalism of Wundt.—Wundt's metaphysics will form an appropriate conclusion of this sketch of German idealism, because his patient industry and ecletic spirit have fitted him to assimilate many of the views of his predecessors. Wundt proves that all idealisms are in a way one. He starts as a phenomenalist from the hypothesis, which he and Fechner especially, always maintained, that our experience contains subject and object in inseparable connexion, and has something in common with the premature attempt of Avenarius to develop the hypothesis of dualism in experience into a scientific philosophy comprehending the universe in the simplest possible manner. Again he agrees with the reaction both to Hume and to Kant in limited knowledge to mental phenomena, and has affinities with both to feeling. His main sympathies are with the Neo-Kantians, and especially with Lange in modifying the a priori, and in extending the power of reason beyond phenomena to an ideal world; and yet the cry of his phenomenalism is not "back to Kant," but "beyond Kant." Though no noumenalist, in his detailed studies with Fechner in psychology, in psychophysical parallelism, in the independence of the physical and the psychical chains of causality, in reducing physical and psychical to a difference of aspects, in substituting impulse for accident in organic evolution, and in wishing to recognize a gradation of individual spiritual beings, with Schopenhauer and Hartmann in voluntarism; and even in his own antithesis of scholastic method, to bring experience under notions, and to unite subject and object in one concrete reality. He has a special relation to Fichte in developing the Kantian activity of consciousness into will and substituting activity for substantiality as the essence of soul, as well as in breaking down the antithesis between phenomena and things in themselves. At the same time, in spite of his sympathy with the whole development of idealism since Kant, which leads him to reject the thing in itself, to modify a priorism, and to stop at transcendental "ideals," without postulates of practical reason, he nevertheless has so much sympathy with Kant's Kritik as its theories of sense and understanding to build up a system of phenomenalism, according to which knowledge begins and ends with ideas, and finally on its theory of pure reason to accord reason a power of logically forming an "ideal" of God as ground of the moral "ideal" of humanity—though without any power of logically inferring any corresponding reality. He constructs his system on the Kantian order—sense, understanding, reason and exhibits most clearly and most necessarily the idea we have of the empirical idea. His philosophy is the best exposition of the method and argument of modern idealism—that we perceive the mental and, therefore, all we know and conceive is the mental.

Wundt founds his whole philosophy on four psychological positions: his phenomenalistic theory of unitary experience, his voluntarism, his individualistic theory of soul, and his psychological theory of parallelism. They are positions also which deeply affect, not only the psychological, but also the metaphysical idealisms of our time, in Germany, and in the whole civilized world.

1. His first position is his phenomenalistic theory of unitary experience. According to him, we begin with an experience of ideas, in which object and idea are originally identical (Vorstellungs-object); we divide this unitary experience into its subjective and objective parts; we confine all thought to abstract ideas, and regard the objects as to be believed at least to be independent things; but it is the office of psychology to warn us against this popular dualism, and to teach us that there is only a duality of psychical and physical, and no genuine antithesis of the general content of our immediate experience; and experience is our whole knowledge. His metaphysical deduction from this psychological view is that we all know is mental phenomena, of the whole outer world of facts is our only in our ideas, and all that we reason logically do beyond these phenomena is to frame transcendental "ideals."

2. His second position is his voluntarism. He agrees with Schopenhauer that the will is ground for all spiritual activity. He does not mean that will is the only mental operation; for he recognizes idea derived from sensation, and feeling, as well as will. Moreover, he contends that we can neither have idea without feeling, and will, nor without idea and feeling; that idea alone wants activity, and will alone wants content; that will is idea and activity (vorstellende Thatigkeit), which always includes motives.
and ends and consequently ideas. He is therefore a follower of Schopenhauer as corrected by Hartmann. Like these predecessors, and like his younger contemporary Paulsen, in calling will fundamental he includes impulse (Trieb). Accordingly, he divides will into impulses and rests on the hypothesis that one has simple volition feelings, which in his view requires as motive a feeling directed to an end, and therefore an idea, e.g. the impulse of a beast arising from hunger and sight of prey; on the other hand, complex volition issuing in a voluntary act, requiring the decision of an idea and the adoption of a motive, with or without choice. Like other German voluntarists, he imputes “impulsive will” to the whole organic world. He follows Fechner closely in his answer to Darwin. If he is correct, one of the important results is that Wundt impulses becoming habits produce structural changes, which are transmitted by heredity; and as an impulse thus gradually becomes mediating automatically, the will passes to higher activities, which in the Wundt view, is thus the active organ of the will.

He supposes that there is a direct relation between thinking and feeling. If this is the case, he concludes, the will is necessary in thinking. Thus, the will is necessary in thinking. Not only is the will the source of the act, but also of the idea. It is in our power whenever one pleases, whereas sense depends on an external stimulus (De anima, ii. 5). There is also an impulse to think, e.g. from toothache. But it does not follow that thought is the source of the act; it is not necessary that thinking without willing should not or will not. The real source of thinking is evidence. Wundt, however, having supposed that all thinking consists of ideas, next supposes that all thinking is willing. What is the source of this willing? There are the brute impulses that are the substratum of both. He supposes that all agency, and therefore the agency of thinking, is will. In detail, to express this supposed inner will of thinking, he borrows from Leibnitz and Kant the term “apperception” as an act of consciousness, and identifies the latter with the former. Kant, from unconscious perception, gave the name “apperception” to consciousness. Kant further insisted that this apperception, “I think,” is an act of spontaneity, distinct from sense, necessary to the very idea of reality, as well as that of Kant, requiring for its existence, nothing but inner consciousness. In apperception we require the result, and that indeed all activity is will, infers that apperception is inner will. Further, on his own account, he identifies apperception with the process of attention, and regards it as a faculty. The same is the case with the mind in all association of ideas, to all imagination and understanding. According to him, then, attention, even involuntary attention, requires inner will; and all the functions imputed by Hume to association, as well as those imputed to understanding by Kant, require apperception, and therefore inner will. At the same time he does not suppose that they all require the same kind of will. In according with his previous division of outer will into impulsive and rational, he suggests that the will native to the act of apperception and active apperception. Apperception in general thus becomes activity of inner will, constituting the process of attention, passive in the form of impulsive will required for association, and active in the form of rational will involved in apperception and judgment. Now, beneath these confusing phrases the point to be regarded is that, in Wundt’s opinion, though we can receive sensations, we cannot think at all beyond sense, without some will.

This does not, however, go far enough. It would be perfectly possible to think of the position of little man in the great world at the mercy of things which drive him perforce to sense and from sense to thought. It is a substitution of will for evidence. Where evidence partakes of will and of sensation in the same way that we often believe against our will (e.g. that we must die), often without even an impulse to believe, often without taking any interest, or when taking interest in something extraneous, that is directly against the contrary). Yet many psychologists accept the universality of this will, and to believe, and among them James, who says that “it is far too little recognized how entirely the intellect is habit,” is an important instance.

Wundt, however, goes still farther. According to him, that which acts in all organisms, that which acts in all thinking, that which divides unitary experience into subject and object, the source of self-consciousness, the unity of our mental life, “the most proper being of the individual subject is will.” In short, his whole voluntarism means that, while the inorganic world is mere object, all organization is congealed will, and all thinking is the union of will and object, a development which his way of regarding the will requires. In this case, Wundt concludes are arrived at by confusing action, reaction, life, excitability, impulse, and rational desire, all under the one word will, as well as by omitting the involuntary action of intelligence under the name of will. Yet, Wundt a volition, is巴斯, a volition is the beginning of mind; but then the order of mind is feeling, sense, inheritance, will, which instead of first is last, and implies the others. To proceed, however, with voluntarism, Wundt, as we have seen, believes in the usefulness of the will. He accepts the universal voluntarism of Schopenhauer and Hartmann, but believes in it only as an inner spirit, and a gradation of wills, in the organic world. Similarly, he supposes that the personal individual will contains inner will-unity, and thinks that this conclusion is proved by the continuance of actions in animals after parts of the brain have been removed. In a similar manner, Wundt does not, however, think with Schuppe that there is one common consciousness, but only that there is a collective consciousness and a collective will; not perceiving that the act in his view a more object in the experience of every member of the collection—would be only a collective sun. Lastly, he believes that reason forms the “ideal” of God as world-will, though without proof of existence. On the whole, his volun-

trary is not the same, however, he supposes that the only supposed to extend through the whole of the world of things, the whole inorganic world remains a mere object of unity experience.

iii. His third position is his actualistic theory of soul, which he shares with Fechner in many details. If Schopenhauer had rejected the Kantian soul in itself and developed the Kantian activity of apperception, he considered that soul consists in constructive activity. Fechner added that the soul is the whole organism, and thus implies that the will is an act without being a substance. Wundt accepts Fichte’s theory of the actuality, and Fechner’s synecdochical view of the soul. Taking substance entirely in the sense of substrate, he concludes that the soul is the whole organism, and that the soul as such is identical with the whole unitary activity of the organism, the whole inorganic world remains a mere object of unity experience.

iv. Hence his fourth point is his psychological theory of parallelism. As a physiological and psychical theory, he is the first to acknowledge the truth of the dualism, and thus of the parallelism that every psychical process has a physical accompaniment, every physiological function has a psychical meaning, but neither external stimulus nor physiological stimulus is adequate to power in the physiological process. In this view, Wundt holds that there is a physical causality and energy and there is a psychical causality and energy, parallels which never correspond exactly; and he concludes how the mind performs mental activities consciously (see case Physical Realism, ch. v.). Wundt, however, has satisfied himself, like Fechner, that there is no real opposition of body and soul, and concludes, as Hartmann does, that the soul is an activity of the body. If, then, these mental operations were merely actuality, they would be actuality of a man’s bodily substance. In truth there is no sound answer to Materialism, except that, besides bodily functions which are self-sufficient, there are mental functions which are self-sufficient.

PHENOMENAL/IDEALISM

METAPHYSICS
my body, is merely an object abstracted from an idea of my experience; and what is really known in every case is a unitary experience; divisible, but not separable, into body and soul, physical and psychical factors of one and the same unitary experience. Wundt, however, has added a notion of causality, and what we know is mental phenomena, ideas regarded as objects and subjects of experience.

In contradiction to this, Wundt’s philosophy consecutively follows, beginning with his psychology. He begins with psychical elements, sensations and feelings, but he asserts that these always exist in a psychical compound, from which they can be separated. He concludes that there is an analysis and synthesis, and that a pure sensation is an abstraction is repeated by W. James. Further, Wundt declares that the psychical compound of sensations, with which, according to him, we actually start, is not a complex simple sensation: it is an idea or a compound idea, as the case may be. Wundt says that, when I hear the chord of D, I am not conscious of single sensations of D, F, A, and have only a compound idea of the chord—as if the hearing of music were merely a series of ideas! Wundt, however, proceeds to substitute a term for sub-sensation and idea that accepts Lotze’s hypothesis of logical signs, and adds a hypothesis of temporal signs. He supposes that we have no sensations of space and time, as the natsivists suppose, but that, while local signs give us spatial ideas, feelings of expectation are temporal signs giving us temporal ideas, and that these ideas enter into the psychical compound, which is our actual starting-point. It follows that every psychical compound into which temporal and spatial ideas enter must be analyzed and then added together, if one wants to find sensations, it follows that every psychical compound of sensations, containing as it does, always temporal, if not also spatial, ideas, must be a compound idea, and not, as natsivists suppose, Schuppe for instance, sensation compounded from a number of psycho-motor sensations. Wundt’s answer is that inner impulsive will, in the form of passive apperception, forms compound ideas by association; so that all these operations are necessary to the starting-point. He proceeds to say that the process of apperception is merely a fusion (Vermischung), and supposes that it is a fundamental process of fusung sensations with spatial and temporal ideas into a compound idea. But he also recognizes association of ideas (Leibnitzian synthesis). He says that an idea may be more confused in the sense of the world, and association by contingency, or complication. Recognizing then, three kinds of association in all, he supposes that they are the first processes, by which inner, in fact, all real syntheses of compound ideas take place. So far his psychology is a further development of Hume’s. He does not agree with Hume that mind is nothing but sensations, ideas, and associations, but with Kant, that there are higher complications. According to him, inner decisive apperception, the process called apperception, proceeds to what he calls “apperceptive combinations” (Apperzeptionveränderungen); first to simple combinations of relating and comparing, and then to complex combinations of synthesis and analysis in imagination and understanding; in consequence of which synthesis issues in an aggregate idea (Gesammt- 

In his logic, and especially in his epistemology, Wundt appears as a mediator between Hume and Kant, but with more leaning to the latter. While he regards association as lying at the basis of all knowledge, he does not deny it, as Kant does, that Hume that he does not account for necessity, nor for substance and causation as known in the sciences. He accepts on the whole system of synthetic understanding which Kant superimposed on Hume’s, and made it conformable to his transcendentalism. Between Hume’s posteriori and Kant’s a priori hypothesis he proposes a logical theory of the origin of notions beyond experience. He explains that the arrangement of the mind as a logical machine is an immediate inference of judgment, so is inference a mediate, reference of the members of any aggregate of ideas to one another” (System der Philosophie, 66, first ed.). He cannot allow any inference beyond ideas. His psychology poisons his logic.

What kind of metaphysics, then, follows from this compound of psychology and epistemology? As with Kant against Hume, and against Mach and Avenarius, the world we know will contain sensations and ideas, but more of sensations, more than pure experience: with Wundt it will be a world of real causes and some substances, constituted partly by experience and partly by logical thinking, or active inner will. But as with Kant, so with Wundt, this world will be only richer, not the wider, for these notions of understanding; because they are only contributed to the original experience, and, being mentally contributed, only the more surely define knowledge to experience of mental phenomena. Hence, according to Wundt, the world we know is still unitary experience, distinguished, not separated, into subject and object, aggregates of ideas analysed by judgment and combined by inference, an object of idea elaborated into causes and substances by logical thinking. But when a mental thought breaks away out of our sensations, and arranged under our categories of our understanding by our inner wills, or a world of our ideating will; but nothing else. It is Wundt’s own statement of his solution of the epistemological problem “that on the one hand the whole outer world exists for us only in our ideas, and that on the other hand a consciousness without objects of idea is an empty abstraction which possesses no actuality” (System, 212–213). There remains his theory of reason. His pupil, Oswald Külpe (1862–1917), who bases his Grundsätze der Psychologie on the hypothesis of unitary experience, says in his Einleitung in die Philosophie (1895; 4th ed. 1907) that Wundt in his System derives the right of metaphysics to transcend experience from similar procedure.
within the limits of the special sciences. This is Wundt's view, but only in the sense that reason passes from ideas to "ideals," whether in the special sciences or in metaphysics. Reason, as in most modern psychologies and idealisms, is introduced by Wundt, after all sorts of operations, too late; and, when at length introduced, it is described as going beyond ideas and notions to "ideals" (Ideen), as an ideal continuation of series of thoughts beyond given experience—nothing more. Reason, according to Wundt, is like pure reason according to Kant; except that Wundt, receiving Kantism through Neo-Kantism, thinks that reason arrives at "ideals" not a priori, but by the logical process of ground and consequent, and, having abolished the thing in itself, will not follow Kant in his inconsequent passage from pure to practical reason in order to postulate a reality corresponding to "ideals" beyond experience. Wundt, in fact, agrees with Lange: that reason transcends experience of phenomena only to conceive "ideals." This being so, he finds in mathematics two kinds of transcendence—real, where the transcendental, though not actual in experience, can become partly so, e.g. the divisibility of magnitudes; imaginary, which consists in the idea of the same transcendence in forming cosmological, psychological, and ontological "ideals." He supposes real as well as imaginary transcendence in cosmological "ideals"; the former as to the forms of space and time, the latter as to content, e.g. atoms. But he limits psychological and ontological "ideals" entirely to imaginary transcendence. The result is that he confines metaphysical transcendence to "a process into the imaginary" as regards the substantial and causal content of cosmological "ideals," and altogether as regards psychological and ontological "ideals." Thus, according to him, in the first place reason forms a cosmological "ideal" of a multitude of simple units related; secondly, it forms a psychological "ideal" of a multitude of wills, or substance-generating activities, which communicate with one another by ideas so that will causes ideas in will, while together they constitute a collective will, and it goes on to form the moral ideal of humanity (das sittliche Menschheitsideal); and, thirdly, it forms an ontological "ideal" of God as ground of this moral "ideal," or limitation of all being as means to this end, and an "ideal" of God as world-will, of which the world is development, and in which individual wills participate each in its sphere. "Herein," says Wundt, "consists the imperishable truth of the Kantian proposition that the moral order of the world is the single real proof of the existence of God" (System, 405; cf. 439). "Only," he adds, "the expression proof is here not admissible. Rational 'ideals' are in general not provable." As the same limit is applied by him to all transcendent rational "ideals," and especially to those which refer to the content of the notion of the world, and, like all psychological and ontological "ideals," belong to the imaginary transcendental, his conclusion is that reason, in transcending experience, logically conceives "ideals," but never logically infers corresponding realities.

The conclusion that reason in transcending experience can show no more than the necessity of "ideals" is the only conclusion which could follow from Wundt's phenomenism in psychology, logic, and epistemology. If knowledge is experience of ideas distinguished by inner will of apperception into subject and object in inseparable connexion, if the starting-point is ideas, if judgment is analysis of an aggregate idea, if inference is a connecting of the contents of the ideas of one another, then, as Wundt says, all we can know, and all reason can logically infer from such data, is in our ideas, and consciousness without an object of idea is an abstraction; so that reason, in transcending experience, can show the necessity of ideas and "ideals," but infer no corresponding reality beyond, whether in nature, or in Man, or in God. Wundt, starting from a psychology of unitary experience, deduces a consistent metaphysics of no inference of things transcending experience throughout—or rather until he came to the very last sentence of his System der Philosophie (1889), where he suddenly passes from a necessity of "ideals" (Ideen), to a necessity of "faith" (Glauben), without "knowledge" (Wissen). He forgets apparently that faith is a belief in things beyond ideas and ideals, which is impossible in his psychology of judgment and logic of inference. The fact is that his System may easily seem to prove more than it does. He describes it as idealism in the form of ideal realism, because it recognizes an ideating will requiring substance as substratum or matter for outer relations of phenomena. But when we look for the evidence of any such will beyond ourselves and our experience, we find Wundt offering nothing but an ontological "ideal" of reason, and a moral "ideal" requiring a religious "ideal," but without any power of inferring a corresponding reality. The System then ends with the necessity of an "ideal" of God as world-will, but provides no ground for the necessity of any belief whatever in the being of God, or indeed in any being at all beyond our own unitary experience.

Wundt, however, afterwards wrote an Einleitung in die Philosophie (1901; 4th ed., 1906), in which he speaks of realism in the form of ideal realism as the philosophy of the future. It is not to be idealism which resolves everything into spirit, but it is to be an idealism of the spiritual and the material each in its own place in harmony and agreement. It is not to be dualistic but monistic realism, because matter is not separate from spirit. It is not to be materialistic but ideal realism, because the physical and the psychical are inseparable parallels inexplicable by one another. It is to be monistic ideal realism, like that of Fichte and Hegel; not, however, like theirs idealistic in method, a Phantastisches Begriffsgebäude, but realistic in method, a Wissenschaftliche Philosophie. It is to be ideal realism, as in the System—but of realism. How are we to understand this change of front? We can only explain it by supposing that Wundt wishes to believe that, beyond the "ideal," there really is proof of a transcendent, ideating, substance-generating will of God; and that he is approaching the noumenal voluntarism of his younger contemporary Paulsen.

But to make such a conversion from phenomenalism plausible, it is necessary to be silent about his whole psychology, logic, and epistemology, and the consequent limitation of knowledge to experience, and of reason to ideas and "ideals," without any power of inferring corresponding things.

What a pity it is that Wundt had committed himself by his psychology to phenomenalism, to unitary experience, and to the limitation of judgment and reason to ideas and ideals! For his phenomenalism prevents him from consistently saying the truth inferred by reason—that there is a world beyond experience, a world of Nature, and a will of God, real as well as ideal. To understand Wundt is to discover what a mess modern psychology has made to metaphysics. To understand phenomenal idealism in Germany is to discover what a narrow world is to be known from the transcendental idealism of Kant shorn of Kant's inconsistencies. To understand noumenal idealism in Germany and the rise of metaphysical idealism in modern times is to discover that psychological is the origin of all metaphysical idealism. If we perceive only what is mental, all that we know is only mental. Who has proved that psychological starting-point? Who has proved that, when I scent an odour in my nostrils, I apprehend not odour but the sensation of odour; and so for the other senses? Sensation, as Aristotle said, is not of itself: it is the apprehension of a sensible object in the organism. I perceive pressure, heat, colour, sound, flavour, odour, in my five senses. Having felt reciprocal pressures in touch, I infer similar pressures between myself and the external world.

6.—ENGLISH IDEALISM

1. The Followers of Hume's Phenomenalism.—Compared with the great systems of the Germans, English idealism in the 19th century shows but little originality. It has been largely borrowed either from previous English or from later German idealism, and what originality it has possessed has been mainly shown in that spirit of eclectic compromise which is so dear to the English mind. The predominant influence, on the whole,
has been the phenomenalism of Hume, with its slender store of sensations, ideas and associations, and its conclusion that all we know is sensations without any known thinkers or any other known things. This phenomenalism was developed by James Mill (1773-1836) and J. S. Mill (1806-1873), and has since been continued by A. Bain. It also became the basis of the philosophies of Huxley and of Spencer on their phenomenalistic side. It is true that Spencer's "transfigured realism" contains much that was not dreamt of by Hume. Spencer widens the empirical theory of the origin of knowledge by his brilliant hypothesis of inherited organized tendencies, which has influenced all later psychology and epistemology, and tends to a kind of compromise between Hume and Kant. He describes his belief in an unknowable absolute as "carrying a step farther the doctrine put into shape by Hamilton and Mansel." He develops this belief in an absolute in connexion with his own theory of evolution into something different both from the idealism of Hume and the realism of Hamilton, and rather falling under the head of materialism. Nevertheless, as he believes all the time that everything knowable throughout the whole world of evolution is phenomena in the sense of subjective affections of consciousness, and as he applies Hume's distinction of impressions and ideas as a distinction of vivid and faint states of consciousness to the distinction of ego and non-ego, spirit and matter, inner and outer phenomena, his philosophy of the world as knowable remains within the limits of phenomenalism. Nothing could be more like Hume than his final statement that what we are conscious of is subjective affections produced by objective agencies unknown and unknowable. The "anti-
realism," which takes the lion's share in "transfigured realism," is simply a development of the phenomenalism of Hume. Hume was also at the bottom of the philosophies of G. H. Lewes, who held that there is nothing but feelings, and of W. K. Clifford. Nor is Hume yet dethroned, as we see from the works of Karl Pearson and of William James, who, though an American, has exercised a considerable influence on English thought. The most flourishing time of phenomenalism, however, was during the lifetime of J. S. Mill. It was counteracted to some extent by the study at the universities of the deductive logic of Aristotle and the inductive logic of Bacon, by parts of Mill's own logic, and by the natural realism of Reid, Stewart, and Hamilton, which met Hume's scepticism by asserting a direct perception of the external world. But natural realism, as finally interpreted by Hamilton, was too dogmatic, too unsystematic, and too confused with elements derived from Kantian idealism to withstand the brilliant criticism of Mill's Examination of Sir William Hamilton's Philosophy (1865), a work which for a time almost persuaded us that Nature as we know it from sensations is nothing but permanent possibilities of sensation, and oneself only a series of states of consciousness.

2. The Influence of Kant and Hegel.—Nevertheless, there have never been wanting more soaring spirits who, asked at the narrowness of the popular phenomenalism of Hume, have found a wider idealism. They have, as a rule, sought it in Germany. Before the beginning of the 19th century, Kant had made his way to England in a translation of some of his works, and in an account of the Elements of the Critical Philosophy by A. F. M. Willich, both published in 1788. After a period of struggle, the influence of Kant gradually extended, and, as we see in the writings of Coleridge and Carlyle, of Hamilton and Mansel, of Green and Caird, of Laurie, Martineau and others, has secured an authority over English thought almost equal to that of Hume (see IDEALISM). Both philosophers appeal to the English love of experience, and Kant had these advantages over Hume: that within the narrow circle of sensible phenomena his theory of understanding gave it to experience a fuller content, and that beyond phenomena, however inconsistently, his theory of reason postulated the reality of God, freedom and immortality. Other and wiser German philoso-
phies gradually followed that of Kant to England. Coleridge (1772-1834) not only called attention to Kant's distinction between understanding and reason, but also introduced his countrymen to the noumenal idealism of Schelling. In the Biographia Literaria (1817) he says that in Schelling's Naturphilosophie und System des transcendentalen Idealismus he first found a general coincidence with much that he had toiled out for himself, and he repeated some of the main tenets of Schelling. Carlyle (1795-1881) laid more emphasis on Fichte. At the height of his career, when between 1840 and 1850 many of Fichte's works were being translated in the Cathlic Series, he called attention to Fichte's later view that all earthly things are but a vesture or appearance under which the Divine idea of the world is the reality. Extravagant as this noumenalism is, it was a healthy antidote to the phenomenalism of the day. Among other followers of German idealism were J. F. Ferrier (q.v.), who adopted the hypothesis of Schelling and Hegel that there is one absolute intelligence (see his Lectures and Philo-
osophical Remains, 1866, i. 1-33; ii. 545-568), and J. Hutchinson Stirling (q.v.). About the same time Benjamin Jowett (q.v.) had been studying the philosophy of Hegel; but, being a man endowed with much love of truth but with little belief in first principles, he was too wise to take for a principle Hegel's supposi-
tion that different things are the same. He had, however, sown seeds in the minds of two distinguished pupils, T. H. Green and E. Caird (q.v.). Both proceeded to take Hegelianism seriously, and between them spread a kind of Hegelian orthodoxy in metaphysics and in theology throughout Great Britain. Green (Prolegomena to Ethics, 1883) tried to effect a harmony of Kant and Hegel by proceeding from the epistemology of the former to the metaphysics of the latter. Taken for granted the Kantian hypothesis of a sense of sensations requiring synthesis by under-
standing, and the Kantian conclusion that Nature as known consists of phenomena united by categories as objects of experi-
ence, Green argued, in accordance with Kant's first position, that knowledge, in order to unite the manifold of sensations by relations into related phenomena, requires unifying intel-
ligence, or what Kant called synthetic unity of apperception, which, on itself be sensation, because it arranges sensations; and he argued, in accordance with Kant's second position, that therefore Nature itself as known requires unifying intelligence to constitute the relations of its phenomena, and to make it a connected world of experience. When Green said that "Nature is the system of related appearances, and related appearances are impossible apart from the action of an intelligence," he was speaking as a pure Kantian, who could be answered only by the Aristotelian position that Nature consists of related bodies beyond appearances, and by the realistic supposition that there is a tactical sense of related bodies, of the inter-resisting members of the organism, from which reason infers similar related bodies beyond sense. But now, whatever opinion we may have about Nature, at all events, as Green saw, it does not come into exist-
ence in the process by which this person or that begins to think. Nature is not my nature, nor your nature, but one. From this fact of unity of Nature and of everything in Nature, combined with the impossibility of separating them, Green proceeded to argue, altogether beyond the spirit of Kant, that Nature, being one, and also requiring unifying intelligence, requires one intelligence, an eternal intelligence, a single spiritual principle, prior to, and the condition of, our individual knowledge. According to him, therefore, Nature is one system of phenomena united by relations as objects of experience, one system of related appearances, one system of one eternal intelligence which reproduces itself in us. The "true account" of the world in his own words is "that the concrete whole, which may be described indiscriminately as an eternal intelligence realized in the related facts of the world, or as a system of related facts rendered possible by such an intelligence, partially and gradually repro-
duces itself in us, communicating piecemeal, but in inseparable correlation, understanding and the facts understood, experience and the experienced world." Nobody can mistake the Schellin-
gian and Hegelian nature of this conclusion. It is the Hegelian view that the world is a system of absolute reason. But it is
not a Kantian view; and it is necessary to correct two confusions of Kant and Hegel, which have been imported with Hegelianism by Green and Caird. Ferrier was aware that in Kant's system: "there is no common nature in all intelligence" (Lectures, ii. 568). Green, on the other hand, in deducing his own conclusion that the world is, or is a system of, one eternal intelligence, incautiously put it forward as "what may be called broadly the Kantian view" (Prolegomena, § 36), and added that he follows Kant "in maintaining that a single active consciousness, by whatever name it be called, is necessary to constitute such a world, as the condition under which all phenomena, i.e. appearances to consciousness, can be related to each other in a single universe" (§ 38). He admitted, however, that Kant also asserted, beyond this single universe of a single principle, a world of unknowable things in themselves, which is a Kantian not a Hegelian world. But Caird endeavoured to break down even this second barrier between Kant and Hegel. According to Caird, Kant "reduces the inaccessible thing in itself (which he at first speaks of as affecting our sensibility) to a noumenon which is projected by reason itself" (Essays, ii. 465); and in the Transcendental Dialectic, which forms the last part of Kant's Kritik, the noumenon becomes the object of a sintulative intuition: "as a thing in itself, which is one with the existence of the objects it knows" (ibid. 412, 413). Kant, then, as interpreted by English Hegelians, already believed, before Hegel, that there is one intelligence common to all individuals, and that a noumenon is a thought of this common intelligence, "an ideal of reason"; so that Kant was trying to be a Hegelian, holding that the world has no being beyond the thoughts of one intelligence. But history repeats itself; and these same two interpretations of Kant had already been made in the lifetime of Kant by Fichte, in the two Introductions to the "Wissenschaftslehre," which he published in his Philosophical Journal in 1797. Now, the curious fact is, that Kant himself wrote a most indignant letter, dated 7th August 1790 (Kant's Werke, ed. Hartenstein, vili. 600-601), on purpose to repudiate all connexion with Fichte. Fichte's "Wissenschaftslehre," he said, is a completely untenable system, and a metaphysics of fruitless apices, in which he disclaimed any participation; his own Kritik he refused to regard as a propaedeutic, to be construed by the Fichtian or any other standpoint. Pointing out that the Fichtian system is inadequate, he goes on to say that Kant, in the letter; and he went so far as to assert that his own critical philosophy is so satisfactory to the reason, theoretical and practical, as to be incapable of improvement, and for all future ages indispensable for the highest ends of humanity. After this letter it cannot be doubted that Kant not only differed wholly from Fichte, both about the synthetic unity of apperception and about the thing in itself, but also is to be construed literally throughout. When he said that the act of consciousness "I think," is in allem Bewusstsein ein und dasselbe, he meant, as the whole context shows, not that it is one in all thinkers, but only that it accompanies all my other ideas and is one and the same in all my consciousness, while it is different in different thinkers. Though again in the Transcendental Dialect he spoke of pure reason conceiving "ideals" of noumena, he did not mean that a noumenon is nothing but a thought arising only through thinking, or projected by reason, but meant that pure reason can only conceive the "ideal" while, over and above the "ideal" of pure reason, a noumenon is a real thing, a thing in itself, which is not known, but determined by practical reason in the three instances of God, freedom, and immortality. Consequently, Kant's explanation of the unity of a thing is that there is always one thing in itself causing in us many phenomena, which as understood by us are objectively valid for all our consciousnesses. What Kant never said and what his whole philosophy prevented his saying, was that a single thing is a single thought of a single consciousness; either of men, as in Fichte's philosophy, or of God and man, as in Hegel's. The passage from Kant to Hegel attempted by Green and Caird, are unhistorical, and have caused much confusion of thought. The success, therefore, of the works of Green and Caird must stand or fall by their Hegelianism, which has indeed secured many adherents, among critical and partly theological. Among the former we may mention W. Wallace, the translator of most of Hegel's Encyclopaedie, who had previously learnt Hegelianism from Ferrier; W. H. Fairbrother, who has written a faithful account of The Philosophy of Thomas Hill Green (1836); R. L. Nettleship, D. G. Ritchie, J. H. Muirhead, J. S. Mackenzie, and J. M. E. M'Taggart, who closes his acute Studies in Hegelian Cosmology (1901) with "the possibility of finding, above all knowledge and volition, one all-embracing unity, which is only not true, only not good, because all truth and all goodness are but distorted shadows of its absolute perfection—das Unbegreifliche, weil es der Begriff selbst ist."

There are still to be mentioned two English Hegelians, who have not confused Kant and Hegel as Green did: namely, Simon Sommerville Laurie (1829-1909) and F. H. Bradley (b. 1846), fellow of Merton College, Oxford. Laurie, wrote Metaphysica, nova et velutina, a Return to Dualism, by Sections Novem (1839 and enlarged 1840). His attitude to Green is expressed towards the end of his book, where he says: "The more recent argument for God which resolves itself into the necessity of a self-distinguishing one basis to every truth, . . . modifying thereby what has been the simple old argument of the necessity for a First Cause dressed up in new clothes. Not by any means an argument to be despised, but stopping short of the truth through an inadequate analytic of the concepts. His method of philosophy is based on the conviction that a true metaphysics is at bottom psychology, and a true psychology fundamentally metaphysics. His psychology is founded on a proposed distinction between "true" and "real" as regards our knowledge of things, so that we suppose that we become conscious of objects outside ourselves, is his "return to dualism," and is indeed so like natural realism as to suggest that, like Ferrier, he starts from Hamilton to end in Hegel. As, however, he supposes that we have direct perception of something resisting the organization of an organism, that has been maintained, it becomes necessary to state exactly what he means by "attuition." It is, according to him, something more than sensation, but less than perception; it is common to us with lower animals such as dogs; its operation consists in co-ordinating sensations into a aggregate which the subject throws back into space, and thereby has a consciousness of a total object outside itself, e.g. a stone or a stick, a man or a moon. He carries its operation before reason still further, supposing that "attuition" makes particular inferences about outside objects, and that a man, or a dog, through association "attuities" sequence and invariableness of succession, and, in fact, gets as far in the direction of causation as he can. He says: 'but that the dog who has no higher faculty than "attuition," can go no farther; but that a man goes farther by reason. He thinks that "attuition" gives us consciousness of an object, but without knowledge, and that knowledge begins by a "relational" act, whereby it is brought in contact with the German idealists: he accepts from Kant the hypothesis of synthesis and a priori categories, from Fichte the hypothesis that will is necessary to reason, from Schelling and Hegel the hypothesis of universal reason, and of an identity of the human with the divine and the divine with God. But he has a peculiar view of the powers of reason; that (1) under the law of excluded middle it states alternatives, A or B or C or D; (2) under the law of contradiction it negates both A and B; consequently, by reason of the law of identity, A is B; and (3) under the law of identity it concludes, A is B. In working out this process he supposes that reason throws into consciousness a priori categories, synthetic predicates a priori, or, as he also calls them, "attuities", and thereupon finds, by deductive reasoning, of which his theory, in short, is that by this a priori category and the process of reason we go on from sequence to consequence; first stating that an effect may be caused by several alternatives, then proving that such and such an effect is the result of the reason of which the hypothesis is due, or, as he says, "attuition," and finally attaining the necessity of the causal nexus by converting causality into identity, e.g. instead of "Fire burns wood," putting "Fire is combustible, wood is combustible." Lastly, while he agrees with Kant about a priori categories, he differs about the knowledge of being, and draws all his conclusions, not only to sensations, concluded that we can know nothing beyond our means. But Laurie, applying to them "attuitions" of objects outside, considers that, though they are "reason-born," yet they make us know nothing of the things outside which are known and the objects of knowledge. There is the farthest point of his dualism, which suggests a realistic theory of knowledge, different in process from Hamilton's, but with the same result. Not so: Laurie is a Hegelian, using Kant's categories, but interpreting them in a different way, which is indeed a bold thing but there is the same object and the same thought. At first in his psychology he speaks of the "attuition"
and the rational perception of an outside object. But in his metaphysics founded thereon he interprets the outside object to mean an object outside you and me, but not self-substantive; not outside universal reason, but only "Bétri reason." He quotes with approval the phrase "straightforward Intelligence visible Intellect be Nature!" He agrees with Hegel that there are two fundamental identities, the identity of all reason, and the identity of all reason and all being. Hence he explains, what is a thing in two senses. In one sense, "it" is a thing in its essence; in the other, "it" is a thing in its relation to its own essence. In this latter sense, it is a thing in which there is a contradiction, as Aristotle said between a man being determined by many attributes, such as rational, six-foot-high, white, and a father, and yet being one whole substance distinct from any other, including his own son; nor is there any contradiction between his body being in bed at 8.15 and at breakfast at 8.45 within the same hour. Bradley's supposed contradictions are really mere differences. So far he reminds one of Herbart, who founded his "realistic" metaphysics on similar misunderstandings; except that, while Herbart concluded that the world consists of a number of simple "reals," each with a simple quality but unknown, Bradley concludes that reality is one absolute experience which harmonizes the supposed contradictions in an unknown manner. If his starting-point recalls Herbart's method of arriving at the absolute recalls Spinoza.

His Table of Contents, ch. xiii., on the General Nature of Reality, he says, in true Spinozistic vein, "The Real is one substantially. Plurality of Reals is not possible." In the text he explains that, if there were a plurality of reals, they would have to be beings independent of each other, and yet, as a plurality related to each other—and this again seems to him to be a contradiction. Throughout the rest of the work he often repeats that a thing which is related cannot be an independent thing. Now, if "independent" means "existing alone" and unrelated the same thing could not be at once related and independent; and, taking substance as independent in that sense, Spinoza concluded that there could only be one substance. But this is not the sense in which a plurality of things would have to be independent in order to exist, or to be substances in the Aristotelian sense. "Independent" (διαφορως), or "self-substantive" (kai's aoros) means "existing apart," i.e., existing differently: it does not mean "existing alone," solitary, unrelated. This existing apart is the only sense in which a plurality of things need be independent in order to be real, or in order to be substances; and it is a sense in which they can all be related to each other, as I am not you, but I am addressing you. There is no contradiction, then, though Bradley supposes one, between a thing being an individual, independent, self-substantive substance, existing apart as a distinct thing, and being also related to other things. Accordingly, the many things of this world are not self-discrepant, as Bradley says, but are distinct and relative substances, as Aristotle said. The argument, therefore, for one substance in Spinoza's Ethics, and for one absolute, the Real, which is one substantially, in Bradley's Appearance and Reality, breaks down, so far as it is designed to prove that there is only one substance, or only one Real. Bradley, however, having satisfied himself, like Spinoza, by an abuse of the word "independent," that "the finite is self-discrepent," goes on to ask what the one Real, the absolute, is; and, as he passed from Herbert to Spinoza, so now he passes from Spinoza to Kant. Spinoza answered realistically that the one substance is both extended and thinking. Bradley answers ideally realistically that the one Real is one absolute experience, because all we know is experience. "This absolute," he says, "is experience, because that is really what we mean when we predicate or speak of anything." But in order to identify the absolute with experience he obliged, as he before abused the words "contradictory" and "independent," so now to abuse the word "experience," "Experience," says he, "may mean experience only direct, or indirect also. Direct experience I understand to be confined to the given simply, to the merely felt or presented. But indirect experience includes all fact that is constructed from the basis of the 'this' and the 'mine.' It is all that is to be taken to exist beyond the bare moment" (248). This is to substitute "indirect experience" for all inference, and to maintain that when, starting from any "direct experience," I infer the back of the moon, which is always turned away from me, I nevertheless have experience of it; nay, that it is experience. Having thus confused contradiction and difference, independence and solitariness, experience and inference, Bradley is able to deduce finally that reality is not different substances, experienced and inferred, as Aristotle thought it, but is one absolute super-personal experience, to which the so-called plurality of things, including all bodies, all souls, and even a personal God, is appearance—an appearance, as ordinarily understood, self-contradictory, but, as appearing to one spiritual reality, somehow reconciled. But how?

3. Other German Influences.—Brief reference only can be made to four other English idealists who have quarried in the rich mines of German idealism: G. H. Lewes, W. K. Clifford, G. J. Romanes and Karl Pearson. Lewes (q.v.), starting from the phenomenonalism of Hume, fell under the spell of Kant and his successors, and produced a compromise between G. H. Lewes. Hume and Kant which recalls some of the later German phenomenalisms which have been described (see his Problems of Life and Mind). Rejecting everything in the Kritik which savoured of the "metempirical," he yet sympathized so far with Hegel's noumenalism as to accept the identification of cause and effect, though he interpreted the hypothesis phenomenalistically by saying that cause and effect are two aspects of the same phenomenon. But his main sympathy was with Fechner, the gist of whose "interpsychophysics" he adopted, without, however, the hypothesis that what is conscious in us is conscious in the all-embracing spirit of God. His phenomenalism also compelled him to give a more modified adhesion to Fechner's "outer psychophysics." It will be remembered that Fechner regarded every composite body as the appearance of a spirit; so that when, for example, molecular motion of air is said to cause a sensation of sound in me, it is really a spirit appearing as air which causes the sensation in my spirit. This noumenalism would not do for Lewes, who says that air is a group of qualities, and qualities are feelings, and motion is a mode of feeling. What, then, could he make of the external stimulus? Implied by his phenomenalism to say that it is only one feeling causing another in me. He ingeniously suggested that the external agent is one feeling regarded objectively, and the internal effect another feeling regarded subjectively; "and therefore," to quote his own words, "to say that it is a molecular movement which produces a sensation of sound, is equivalent to saying that a sensation of sight produces a sensation of hearing." Accordingly,
ENGLISH IDEALISM

METAPHYSICS

his final conclusion is that "existence—the absolute—is known to us in feeling," and "the external changes are symbolized as motion, because that is the mode of feeling into which all others are translated when objectively considered: objective consideration being the attitude of looking at the phenomena, whereas subjective consideration is the attitude of any other sensible response." He does not say what happens when we use vision alone and still infer that an external stimulus causes the internal sensation. But his metaphysics is an interesting example of a phenomenalist, sympathizing with noumenalists so different as Hegel and Fechner, and yet maintaining his phenomenalism. In this feature the phenomenalism of Lewes is the English parallel to the German phenomenalism of Wundt. At the same time, and under the derivative influence of Wundt, rather than the more original inspiration of Fechner, W. K. Clifford (1845) was working out the hypothesis of psychophysical parallelism to a conclusion different from that of Lewes, and more allied to that of Leibnitz, the prime originator of all these hypotheses. Clifford advanced the hypothesis that the supposed unconscious units of feeling, or psychical atoms, are the "mind-stuff" out of which everything physical and psychical is composed, and are also things in themselves, such as Kant supposed when he threw out the hint that after all " the Ding-an-sich might be of the nature of mind " (see Mind, 1878, p. 67). As a matter of fact, this " mind-stuff " of Clifford is far more like the " petites perceptions " of Leibnitz, from which it is indirectly derived. This hypothesis Clifford connected with the hypothesis of psychophysical parallelism. He maintained that the physical and the psychical are two orders which are parallel without interference; that the physical or objective order is merely phenomena, or groups of feelings, or " objects," while the psychical or subjective order is both a stream of feelings of which we are conscious in ourselves, and similar streams which we infer beyond ourselves, or, as he came to call them, " ejects "; that, if we accept the doctrine of evolution at all, we must carry these evocative streams of feelings through the whole organic world and beyond it to the inorganic world, as a " quasimential fact "; that at bottom both orders, the physical phenomena and the psychical streams, are reducible to feelings; and that therefore there is no reason against supposing that they are made out of the same " mind-stuff," which is the thing-in-itself. The resemblance of this noumenal idealism to that of Fechner is unmistakable. The difference is that Clifford considers " mind-stuff " to be conscious, and denies that there is any evidence of consciousness apart from a nervous system. He agrees with du Bois-Reymond in refusing to regard the universe as a vast brain animated by conscious mind. He disagrees with Fechner's hypothesis of the world-soul, the world-spirit, God, who embraces all psychophysical processes. Curiously enough, his follower G. J. Romanes (1845) took the one step needed to bring Cliffordism completely back to Fechnerism. In his Rede Lecture on Mind and Motion (1883), he said that Clifford's deduction, that the universe, although entirely composed of " mind-stuff," is itself mindless, did not follow from his premises. Afterwards, when the lecture was published in Mind and Motion and Monism (1895), this work also contained a chapter on " The World as an Eject, " in which Romanes again contended against Clifford that the world does admit of being regarded as an eject, that is, as a mind beyond one's own. At the same time, he refused to regard this " world-eject " as personal, because personality implies limitation. He concludes that the integrating principle of the whole—the Spirit, as it were, of the Universe—is something akin to, but immeasurably superior to, the " psychism " of man. With this exception, however, the way in which a school of English philosophers, which originally started from Hume, the most sceptical of phenomenalists, thus gradually passed over to Leibnitz and Fechner, the originators of psychophysical idealism. The Spirit of the Universe contemplated by Romanes is identical with the World-soul contemplated by Fechner.

Karl Pearson (The Grammar of Science, 1892, 2nd enlarged ed., 1900), starting from Hume's phenomenal idealism, has developed views closely allied to Mach's universal physical phenomenology. What Hume called repeated sequence Pearson calls " routine " of perceptions, and, like his master, holds that cause is an antecedent stage in a routine of perceptions; while he also acknowledges that his account of matter leads him very near to John Stuart Mill's definition of matter as " a permanent possibility of sensations." His views, in his chapter on the Laws of Motion, that the physicist forms a conceptual model of the universe by aid of corpuses, that these corpuses are only symbols for the component parts of perceptual bodies, and that force is a measure of motion, and not its cause, are the views of Mach. At the end of this chapter he says that the only published work from the perusal of which he received any help in working out his views in 1882 and 1884, was Mach's Die Mechanik in ihrer Entwicklung (1883). Mach had begun to put them forward in 1872, and Kirchhoff in 1874. But they may well have been developed independent of both in Germany and in England from their common source in Hume. Their point is to stretch Hume's phenomenalism so as to embrace all science, by contending that mechanism is not at the bottom of phenomena, but is only the conceptual shorthand by aid of which men of science cannot briefly describe phenomena, and that all science is description and not explanation. These are the views of Mach and of Pearson, as we read them in the latter's Preface. Nor can we find any difference, except the minute shade that Pearson takes up a position of agnosticism between Clifford's assertion of " mind-stuff " and Mach's denial of things in themselves.

James Ward (q.v.), in Naturalism and Agnosticism (1899), starts from the same phenomenalistic views of Mach and Kirchhoff about mechanisms; he proceeds to the hypothesis of duality within experience, which we have traced in the phenomenalisms of Schuppe, Avenarius and Wundt, and to the hypothesis of one consciousness, which was variously in the German idealisms, not of Kant, as Ward thinks, but of Fichte, Hegel and Schuppe; and somehow he manages to end with the noumenalistic conclusion that Nature is God's Spirit. Though this work evinces a thoroughly English love of compromise, yet it is not merely eclectic, but is animated throughout by the inspiration of his " old teacher, Lotze." Lotze, as we saw, rejected bodily mechanism, reduced known bodies to phenomena, and concluded that reality is the life of God. Ward on the whole follows this triple scheme, but modifies it by new arguments founded on later German phenomenalism.

Under the first head he attacks mechanics precisely as Mach has done (see below). This attack had been consistently carried out it would have carried him not further than to the second head, according to Ward, as according to Wundt, knowledge is experience; we must start with the duality of subject and object, and proceed to explain the unity of experience and the object, and believe, as realists do, that either subject or object is distinct from the unity; moreover, experience requires "conation," because it is to interesting objects that the subject attends; conation is the condition for all synthesis, association and intellective thinking: thinking is doing; presentation, feeling, conation are one inseparable whole; and the unity of the object is due to activity and not to a substrate. But, in opposition to Wundt and in common with the more general idealism of Spencer, Ward believes that the object of knowledge is not a " thing in itself, " but a " thing in process, " the object of experience is the individual, and (2) experience of the race, which is the extension of individual experience, and is variously called, in the course of the discussion, universal, collective, conceptual, rational experience, commonness in general, universality, unity, intelligence, and even after Caird, " a perfect intelligence." He regards this universal experience as the result entirely of intersubjective course, and concludes that its subject is not numerically distinct from the hypothesis of the individual experience, but is the origin of the categories of causality, which he refers to " conation, " and substance, which he attributes to the interaction of active subjects with their environment and to their intercourse with each other. Ward's system, however, is completely idealist. He may explain the unity of the object, and its independence of individual experience, and not of universal experience, holding that the one sun, and the whole world of intersubjective intercourse, or the " trans-subjective " or spiritual, is not independent of the universal experience, pericent of such, is " not independent of the universal experience, but the object of that experience " (ii. 196-197). He applies universal experience
to explain how we come, falsely in his opinion, to believe that the object of experience is an independent thing; and he uses three arguments, which are respectively those of Schuppe, Avenarius and Wundt. He supposes first, that we falsely conclude from the sun's setting or falling off of all men, that the sun or the race may be said, secondly, that by "introduction" we falsely conclude that another's experience is in him and therefore one's own in oneself, while the sun remains outside; and thirdly, that by reification the naturalist confounds the object and psychology the subject, each falsely believes that its own abstract, the sun or the subject, is an independent thing. What, then, could we know from this "duality in experience"? He has a formal theory of inference, but implies throughout that it only transcends perceptions, and perceptual realities or phenomena, in order to conclude with ideas, not facts. When we combine his view of Nature under the first head that what we know in experience, is not knowledge; and under the second head that knowledge is experience, and experience, individual or universal, is of duality of subject and object in the unity of experience, it follows that all we could know from the data would be one experience of the race, one subject consisting of individual subjects, and in Nature some unity and individuality, the unity of this universal experience; and beyond we should be able to form conceptions dependent on the perceptions of individual experience in the unity of universal experience: that is all. There can be no doubt that his system, however complicated and eclectic, is a rationalistic system of phenomena from the most rationalistic conclusions from such phenomenalistic data. Not so Ward, who proceeds to a Natural Theology, on the ground that from a world of spirits to a Supreme Spirit is a possible step. But perhaps Caird's phrase "a perfect intelligence" has beguiled him into thinking that the one subject of universal experience is not mere man, but God Himself. I am not speaking, however, of any subject of individual experience, you should suppose, and that Nature is a whole. Not so, according to Ward; but "God as the living unity and the reality of the common acts of the one Supreme." What then, is the relation of God to the one universal experience, of the experience of the race, which was under the second head the unity in duality of all knowledge? He does not say. But instead of any longer identifying the experience of the race and universal experience, he concludes his book by saying, "Our reason is confronted and determined by universal reason." This is his way of destroying Naturalism and Agnosticism.

4. Personal Idealism.—The various forms of idealism which have been described naturally led in England, even among idealists themselves, to a reaction against all systems which involve the denial of personality. English moral philosophy cannot long tolerate a metaphysics which by merging all minds in one would destroy personality, personal causation and moral responsibility, as James Martineau well said. The result therefore, arose of which the protagonist was Andrew Seth Pringle-Pattison (b. 1856; professor of logic and metaphysics at Edinburgh University from 1880) in his Scottish Philosophy (1885), and Hegelianism and Personality (1887).

"Each of us, he says," and in another passage, "The real self is one and indivisible, and is unique in each individual. This is the unequivocal testimony of consciousness. What makes the Hellenic conception of personality more interesting is that he has so much in common with the Hegelians; agreeing as he does with Hegel that self-consciousness is the highest fact, the ultimate category of thought through which alone the universe is intelligible; and that self-consciousness must be a principle of the universe. He agrees also that there is no object without subject. It is difficult to see exactly where he begins to differ from Hegel; but at any rate he believes in different self-conscious persons; he does not, as Hegel does, attempt to construct a system of thought beginning from the personal experience of one's own self-consciousness; and he is not very clear on the subject, he would have to admit that a thing, such as the sun, is a different object in each person's consciousness; but not a different system of thought; and, but is too much affected by the eclectic notion of reconciling all philosophies. F. C. Schiller (b. 1864, fellow of Corpus Christi College, Oxford), in Riddles of the Sphinx (1891), is a more systematic thinker. He rejects the difference between matter and spirit. He agrees with Leibnitz in the analysis of the material into the immaterial, but with Lotze in holding that the many immaterial elements coexist and interact. At the same time he differs from Lotze's conclusion that their union requires one absolute substance. Again, he thinks that substance is activity; differing from both Leibnitz and Lotze. Lotze, among all the idealists, may be said to have taken up the idea of knowledge in the most independent and materialistic manner. An idealism and a phenomenalism should be made to a work entitled Personal Idealism, Philosophical Essays by Eight Members of the University of Oxford (1902), edited by H. Sturt, and numbering Schiller, as well as G. F. Stout, and others. In a brief essay, "The Ideal and the Real," in Idola theatris, 1908. They do not all agree with each other, or perhaps even with the title. Nevertheless, there is a common tendency in them, and in the University of Oxford, towards the belief that nothing, of whatever kind, can be known except by the aid of ideas or sensations. This is a sort of antithesis between the one and the many has appeared in the United States. Josiah Royce (b. 1855, professor of philosophy, Harvard) believes in the absolute like Green and Bradley, in the unity of a single self-consciousness, which includes both the finite and the infinite. He states "the conscious meanings in one eternal present insight," as he says in The World and the Individual (1900; see also later works). G. T. Ladd (q.v.) also believes in "a larger all-inclusive self," and he is among extreme idealists; but "self" may be made coincident with an infinite being. While Royce is Hegelian, Ladd prefers Lotze, but both believe in one mind. William James (q.v.), on the other hand, in his psychological works shows that the "ego," which he calls "the personal equation," is an indefinitely divisible with a one infinite being. But by a curious coincidence, almost at the time of the appearance of the Essays on Personal Idealism, by Richards (1879); Essays on the Tenfold World, by John G. Bennett, Limits, and Other Essays Illustrating the Metaphysical Theory of Personal Idealism (1901). In fact there has been an increase of philosophical interchange between English and American universities, which is a very good sign.

The advent of personal idealism is a welcome protest against the confusion of God and man in one mind, and against the confusion of one man's mind with another's. The school undoubtedly tends towards realism. I am conscious only of myself as a person, and of my bodily signs. I know the existence of other human persons and minds only through their giving similar bodily signs. If the personal idealist consistently denies other bodies, then the bodily signs become, according to him, only part of his experience, which can prove only the existence of himself. To infer another mind he must infer another body, and the bodily environment including his and other bodies. Again, in being conscious of myself, I am not conscious of my mind in the abstract without my body. I cannot separate touching from my tactile organs, seeing from my eyes, or sensing from my ears. I cannot think my body away. Moreover, I am not conscious of my personal life in all. How do I know that I was born, though I cannot remember it, and that I should die, though I am not now conscious of death? How do I know that I am the same person from birth to death? No, this consciousness, but by knowing the bodies of others—of babies on the one hand, and of old men on the other hand. It is usual to say that the body has not enough unity to be part of the person: the objection is much more true of conscious mind. The truth is that the unity of consciousness but the fact of its existence is the important point. The existence of my consciousness is my evidence for my soul. But it does not prove that I am nothing but soul. As a human person, I am body and soul; and the idealistic identification of the Ego with soul or mind, involving the corollary that my body belongs to the non-Ego and is no part of myself, is the reductio ad absurdum of idealism. Lastly, the personal idealist is right in rejecting the hypothesis of one mind, they are too hasty in supposing that the hypothesis is useless for idealistic purposes. No idealism can explain how we all know one sun, except by supposing that we all have one mind. The difficulty of personal idealism, on the other hand, is to reconcile the unity of the thing with the plurality of thinkers. The unity of the sun can only be explained either ideologically.

For Dr Schiller's views, see further Pragmatism.
REALISM

by supposing it to be one object of one mind, or realistically by supposing it to be one thing distinct from the many minds which think about it. The former alternative is false, the latter true. Personal idealism, therefore, must end in personal realism.

7.—REALISM

1. Metaphysical and Psychological Realism.—Realism is the view that some known things are bodily, and some are mental. At its best, it is the Aristotelian view that both are substances. The modern misunderstanding of "substance" has been a main cause of the confusion of modern thought. Aristotle meant by it any distinct thing; e.g., I, you, an animal, a plant, the earth, the moon, the sun, God. He calls each of these, as existing apart, a thing per se (καθ' ἄρθρο). It is true that, having divided a natural substance into form and matter, he called each element "substance." But these are not primary meanings; and matter, or supposed substratum, in particular, he says, is not actually substance (Met. Z 3) or is only potentially substance (Met. H 1–2).

In modern times, Spinoza, by a mere mistake, changed the meaning of "substance" from "existing apart" to "existing above," and consistently confused that there is only one. Locke took it to mean "substratum," or support of qualities, and naturally concluded that it is unknown. Kant, taking it in the mistaken meaning of Locke, converted it into the a priori category of the permanent substrate beneath the changes of phenomena, and even went so far as to separate it from the thing in itself, as substantia phenomenon from noumenon. When it had thus lost every vestige of its true meaning, Kant’s successors naturally began to speak of things as being distinct without being substances. Fichte began this by saying that ego is activity, and being is life. Hegel said that spirit is not substance but subject, which to Aristotle would have meant that it is not a distinct thing, yet is a distinct thing. Fechner, Wundt and Paulsen have fixed the conclusion in psychology that soul is not substance but unity of mental life; and Wundt concludes from the modern history of the term that substance or "substrate" is only a secondary conception to that of causality, and that, while there is a physical causality distinct from that of substance, psychical causality requires no substance at all.

The result of this confusion is that the moderns have no name at all for a distinct thing, and, being mere slaves of abstract terms, constantly speak of mere attributes, such as activity, life, will, actuality, unity of mental operations, as if they were distinct things. But an attribute, though real, is not a distinct reality, but only a determinant of a substance, and has no being of its own apart from the substance so determined; whereas a substance, determined by all its attributes, is different from everything else in the world. Though, for simplicity and universality of thought, even in science, we must use the abstraction of attributes, and, by the necessity and weakness of language, must signify what are not substances by nouns substantive, we must guard against the over-abstraction of believing that a thing exists as we abstract it. The point of true realism is Aristotle’s point that the world consists of such distinct, though related, things, and therefore of substances, natural and supernatural. Again, the method of true realism is that of Aristotle, and consists in recognizing the independence of metaphysics. The contrary method is psychological metaphysics, which makes metaphysics dependent on psychology, on the ground that the origin of knowledge determines its limits. This is the method which, as we have seen, has led from psychological to metaphysical idealism, by the argument that what we begin by perceiving is mental, and, therefore, what we end by knowing is mental. Now, there is no principle of method superior to that of Aristotle—we must begin with what is known to us. The things best known to man are the things which he now knows as a man. About these known things there is some agreement: about the beginnings of knowledge there is nothing but controversy. We do not know enough about the origin of knowledge to determine its limits. Hence, to proceed from psychology to metaphysics is to proceed from the less to the more known; and the paradoxes of psychological idealism have caused those of metaphysical idealism.

The realist, then, ought to begin with metaphysics without psychological prejudices. He must ask what are known things, and especially what has been discovered in the sciences; in mechanics, in order to find the essence of bodies which is neglected by idealism; in mental science, in order to understand consciousness which is neglected by materialism. With the conviction that the only fair way of describing metaphysics has been to avoid putting forward one system, and even to pay most attention to the dominant idealism, we have nevertheless been driven occasionally to test opinions by this independent metaphysical method. The chief results we have found against idealism are that bodies have not been successfully analysed except into bodies, as real matter; and that bodies are known to exert reciprocal pressure in reducing one another to a joint mass with a common velocity by being mutually impenetrable, as real forces. The chief results we have found against materialism are that bodies evolving account neither for the origin of themselves, their nature, and their fundamental order of resemblance and difference, nor for the nature and origin of consciousness, nor even as yet for their becoming good for indefinite being. Hence we come to the realistic conclusions that among known substances some are bodies, others are souls; that man is body and soul; and that God is a pure soul or spirit. At the same time, while the independence of metaphysics leads us to metaphysical realism, this is not to deny the value of psychology, still less of logic. Besides the duty of determining what we know, there is the duty of determining how we know it. But in order to discharge it, a reform of psychology as well as of metaphysics is required. Two psychological errors, among many others, constantly meet us in the history of idealism—the arbitrary hypothesis of a sense of sensations, or of ideas, and the intolerable neglect of logical inference. Logical inference from sense is a process from sensible to insensible existence. The former error needs something deeper than a Kantian critique of reason, or an Averian criticism of experience; it needs a criticism of the senses. We want an answer to this question—What must we know by the senses in order to enable us to know what we infer by reason in the sciences? Without here aiming at exhaustiveness, we may bring forward against the dominant idealism a psychological theory of sense and reason. By touch I perceive one bodily member reciprocally pressing another in myself, e.g., lip pressing lip; by touch again I perceive one bodily member similarly pressing but not another member in myself, e.g., only one lip pressing; by inference from touch I infer that it is reciprocally pressing another body similar to my other bodily member, i.e., another body similar to my other lip. On this theory, then, founded on the conscious facts of double and single pressure in touch, and on the logic of inference, we have at once a reason for our knowledge of external bodies, and an explanation of the early appearance of that knowledge. The child has only to have its mother’s nipple in its mouth in order to infer something very like the mutually pressing parts of its own mouth. Having thus begun by touch and tactile inference, we confirm and extend our inferences of bodies in Nature by using the rest of the senses. This is not to forget that the five senses are not our whole stock or to confuse inference to body. We have also the inner sense of consciousness which is inexplicable by body alone. By combining, moreover, our knowledge of Nature with our consciousness of our own works, we can infer that Nature is a work of God. Next, finding that He gives signs of bodily works, but no signs of bodily organs, we can infer that God is a Spirit. Finally, returning to ourselves, we can conclude that, while the conscious in God is Spirit without Body, in us it is spirit with body. This final distinction between bodily and spiritual substances we owe to Descartes.

2. The Undercurrent of Modern Realism.—Coming after the long domination of Aristotelian realism, Descartes and Locke, though psychological idealists, were metaphysical realists.

Their position was so illogical that it was easily turned into metaphysical idealism. But their psychological method and
idealism produced another mistake—the tendency to a modicum of realism, as much as seemed to this or that author to follow from psychological idealism. In Germany, since the victory of Kant over Wolff, realism has always been in difficulties, which we can appreciate when we reflect that the Germans by preference apply the term “realism” to the paradoxes of Herbart (1776–1841), who, in order to avoid supposed contradictions, supposed that bodies are not substances, but show (Schein), while “reals” are simple substances, each with a single quality, and all preserving themselves against disturbance by one another, whether physically or psychologically, but not known to be either material or spiritual because we do not know the simple quality in which the nature of the real consists. There have indeed been other realisms in Germany. Tredelenburg (1802–1872), a formidable opponent of Hegel, tried to surmount Kant’s transcendental idealism by supposing that motion, and therefore time, space and the categories, though a priori, are common to thought and being. Dühring, with a similar object, makes matter a common quality. While these realisms come dangerously near to materialism, that of the Roman Catholic A. Günther (1783–1863), “Cartesius correctus,” erected too mystical an edifice on the psychological basis of Leibnizian idealism. Yet Günther’s realism has produced a school, of which the most distinguished representative is the Old Catholic bishop in Bonn, Th. Weber, whose *Metaphysik*, completed in 1891, starting from the ego and the analysis of consciousness, aims at arriving at the distinction between spirit and nature, and at rising to the spirit of God the Creator. Other realistic systems are those of J. H. von Kirchmann (1802–1884), author, among other works, of *Die Philosophie des Wissens* (1864) and *Ueber die Prinzipien des Realismus* (1872); Goswin Uphues (b. 1841; professor of philosophy at Halle), directed against the scepticism of Shute’s *Discourse on Truth*; and Hermann Schwarz (born 1864), who completes the psychological view of Uphues that we can know objects as they are, by the metaphysical view that they can be as we know them. But German realism lacks critical power, and is little better than a weed overshadowed by the luxuriant forest of German idealism.

In France, the home of Cartesian realism, after the vicissitudes of sensationalism and materialism, which became the philosophy of the French, the French mind with the Revolution, the spirit of French Realism. Descartes revived in the 19th century in the spiritualistic realism of Victor Cousin. But Cousin’s psychological method of proceeding from consciousness outwards, and the emphasis laid by him on spirit in comparison with body, prevented a real revival of realism. He essayed to answer Locke by Kant, and Kant by Reid, Maine de Biran and Schelling. From Reid he adopted the belief in an external world beyond sensation, from Biran the explanation of personality by will, from Schelling the identification of all reason in what he called “impersonal reason,” which he supposed to be identical in God and man, to be subjective and objective, psychological and ontological. We start, according to him, from a psychological triptych in consciousness, consisting of sensation, personal will and impersonal reason, which by a priori laws of causality and substance carries us to the ontological triptych of oneself as ego willing, the non-ego as cause of sensation, and God as the absolute cause beneath these relative causes. So far their realism is real. But when we adopt his theory of the monad, and find that it resolves matter into active force and this into animated activity, identifies law with reason, and calls God absolute substance, we see at once that this spiritual realism is not very far from idealism. About 1840, owing largely to the teaching of E. Saisset in the spiritualistic school, the influence of Descartes began to give way to that of Leibnitz. Leibnitz has been used both realistically and idealistically in France. He was taken literally by spiritual realists, e.g. by Paul Janet (q.v.). Janet accepted the traditional ontologico-triplicity—God, souls and bodies—and, in answer to Ravaissin, who called this realism “semi-realism,” rejoined that he was content to accept the title. At the same time, like Cousin, his works show a tendency to underrate body, tending as they do to the Leibnizian analysis of the material into the immaterial, and to the supposition that
which is extended and solid, which may be measured and weighed, is the immediate object of my touch and sight. And this object I take to be matter, and not an idea. And, though I have been taught by philosophers that what I immediately touch or see is but a mere image, yet I have never been able to cover this by the most accurate attention to my own perceptions. No opposition to idealism could be more distinct. Reid, however, did not always express himself so distinctly. Moreover, he and his successors have a peculiar fancy to make the object of common sense coincide with the notion of common sense. He asserted a realism that the whole system broke down under its own weight. Their philosophy contained valuable points. It also contained much that was doubtful, and much that was ill-adapted to the metaphysical state. They may, however, be considered as a school of metaphysics. It is full of appeals to common sense, and of principles of common sense, which Reid also called intuitive first principles, and self-evident truths. It is spelt by Locke's hypothesis that the soul has a pre-established but indeterminate will. Analyzing the will, it asserted a realism of individuals, it admitted a conceptualism of universals. Stewart also said that our knowledge of matter and mind is merely relative. Hamilton went still further; he tried to combine the oil of Reid with the water of Kant; and converting the intuitive into the a priori, he found a further reason for the relativity of knowledge. Our knowledge is relative, Reid maintained, for the mind, only under modification, determined by these faculties themselves. Not only so, but in his review of Cousin ("Philosophy of the Infinite," Philadelphia, 1825), he observed that the test of knowledge, argued that the mind can conceive, and consequently can know, only the limited, and the conditionally limited, that to think is to condition, that all we know either of matter or of ideas, is that, however selective, highest generalizations rise above the finite," and concluded that we cannot conceive nor know the unconditioned, yet must believe in its existence. Nevertheless, in spite of all this Kantism, he adhered to Reid's original anality in a real analysis of the problem of the perception of the external world; but his final view (edition of Reid's works, note D*) consisted in supposing that (1) sensation is an apprehension of secondary qualities purely as affections of the organism; (2) perception is an apprehension of primary qualities as relations of sensations in the organism viewed as non-ego; and (3) a special perception of a so-called "secondo-primary quality consists in the conscious realization of the condition of the external object. He had seen the problem both in the absolute and on perception affected Mannel and Spencer. They were not, however, received without question even by his followers. H. Calderwood, in his Philosophy of the Infinite (1854), made the pertinent objection that, though thought, conception and knowledge are finite, the object of thought may be infinite. Hamilton, in fact, made the double mistake of limiting knowledge to what we can conceive, and confusing the finite with the absolute, or it might be the infinite. We know very little as except as determined by its attributes; but that would not prevent us from inferring something determined as unconditioned, whether infinite or absolute. J. M'Cosh again, in The Presalting Types of Physical Science, presents a new hypothesis of perception in opposition to Hamilton's combination of Scottish and German schools which will not coalesce, and exhorts the former "to throw away its crusts of impressions, instincts, suggestions, and common sense, and give the mind a power of seeing things directly." He has the merit of presenting natural or intuitive realism in its purity.

The common tenet of the whole school is that without inference we immediately perceive the external world, at all events as a resisting something external to our organism. Is it true? There are three reasons against it, and for the view that we perceive a sensible object within, and infer an external object without, the organism. In the first place, there are great differences between the sensible and the external object; they differ in secondary qualities in the case of all the senses; and even in the case of touch, heat felt within is different from the vibrating heat without. Secondly, there is the so-called "subjective sensation," which is an external object as stimulus, most commonly in vision, but also in touch, which is liable to formication, or the feeling of creeping in the skin, and to horrilpitation, or the feeling of bristling in the hair; yet, even in "subjective sensations," we perceive something sensible, which, however, must be within, and not outside, the organism. Thirdly, the external world and the senses always act on one another by cause and effect and by pressure, although we only feel pressure by touch. Now, when the thing with which touch is in a state of reciprocal pressure is external, e.g. a table, we feel our organism pressed and pressing; we do not feel the table pressing and pressed, but infer it. The Scottish School never realized that every sensation of the five senses is a perception of a sensible object in the bodily organism; and that touch is a perception, not only of single sensible pressure, but also of double sensible pressure, a perception of our bodily members sensibly pressing and pressed by one another, from which, on the recurrence of a single sensible pressure, we infer the pressure of an external thing for the first time. Intuitive Realism is to be replaced by Physical Realism.

3. Reaction to Hypothetical Realism.—The three evidences, which are fatal to intuitive realism, do not prove hypothetical realism, or the hypothesis that we perceive something mental, but infer something bodily. This illogical hypothesis, which consists of incanquently passing from the truth that the sensible object perceived is not external but within the organism to the non-separation that therefore it is within the mind, derived what little plausibility it ever possessed from three prejudices: the first, the scholastic dogma that the sensible object is a species sensibilis, or immaterial sensible form received from the external thing; the second, the Cartesian a priori argument that the soul as thinking thing can perceive nothing but its own ideas; the third, the common assumption of a sense of sensations. But notwithstanding its illogicality, its tendency to undermine Nature as inferred from such idealistic premises, and its certain transition into a consistent idealism, hypothetical realism has, with little excuse, revived among us in the writings of Shadworth Hodgson, James Martineau and A. J. Balfour. The cause of this anachronism has been the failure of intuitive realism and the domination of idealism, which makes short-sighted men suppose that at all events they must begin with the psychology of the logical idealism of the day, in the false hope that on the sands of psychological idealism they may build a house of metaphysical realism.

Shadworth Holloway Hodgson (born 1832; hon. fellow of Corpus Christi College, Oxford), whose chief work is The Metaphysic of Experience (4 vols., 1898), believing that philosophy is an analysis of the contents of consciousness, or experience, and that this is metaphysics, begins, like Kant, with an analysis of experience. Like Kant, he supposes that experience is concerned with sensations, distinguishes matter and form in sense, identifies time and space, eternal time and infinite space, with the formal element, and substitutes synthesis of sensations of touch and sight for association and inference, as the origin of our conception of such a thing as a material object as a bell. Although he does not agree with Kant that either the formal element of sense or the synthesis of sensations is a priori, yet in very Kantian fashion, through not distinguishing between operation and object, he holds that, in synthetically combining sensations of touch and sight, we not only have a complex perception of a solid body, but also know this "object thought of" as itself the complex of these sensations objectified. Hence he concludes that "matter is the name for the sensation-elements derived from both senses, abstracting in thought, 'so far as possible, from the extension-elements of both' (i. 296).

Here you would expect him to stop, as the German Neo-Kantism of Lange stops, with the consistent conclusion that all we know of things is their effect on our senses. But he continues, with a leap, that the complex of sensations needs accounting for, we infer a real condition, e.g. the solid interior of a bell. What we know, however, of this condition, according to him, has two limits: on the one hand, it is the condition only of the existence of our sensations; on the other hand, all we know of its nature is our perceptions. Matter thus, which had at first been defined as a complex of perceptions objectified, now turns...
out to be a condition without which perceptions would not exist, but whose nature is known only as a complex of perceptions. Finally, according to him, having inferred matter as the condition of our perceptions, we are entitled to infer that the condition of the existence of matter is God, whose nature, however, can be inferred only by practical reason from conscience. He avers that this "metaphysics of experience" is not idealism, or the tenet that consciousness is the only reality. It is realism—but inconsistent and inadequate realism, something of an illusion, at best. In accordance with our knowledge of the distinction between Nature as condition of sensations and God as condition of Nature; but very like in holding that all we know of natural forces is our perceptions. We know more, however, about a body, such as a bell, than a sense, and the lockjaw of Nature.

Metaphysics
